Immobilization-related bone loss occurs in many neurological conditions including stroke, spinal cord injury (SCI), Parkinson's disease, multiple sclerosis, and amyotrophic lateral sclerosis. The rapid and extensive sublesional bone loss after SCI is a difficult medical problem that has been refractory to available interventions except the potent anti-resorptive agent, denosumab (a human monoclonal antibody to RANKL). While promising, this agent has potential to suppress bone formation that might be associated with adverse side effects, highlighting a critical need to develop better treatment options. We previous reported an ability of low-intensity vibration (LIV) to improve selected biomarkers of bone turnover and gene expression and to reduce osteoclastogenesis. In this study, we demonstrate for the first time that a prolonged course of LIV for 8 weeks can protect against loss of bone after SCI in rats. LIV stimulates bone formation and improves osteoblast differentiation potential of bone marrow precursors while inhibiting osteoclast differentiation potential of bone marrow precursors and reducing bone resorption. We further demonstrate a combination of LIV and RANKL antibody reduces SCI-related bone loss more than each intervention alone. Our findings indicate that LIV is efficacious in maintaining sublesional bone mass, suggesting that such physical-based intervention approach would be noninvasive, simple, inexpensive and easy to implement in the treatment of bone loss after SCI. The data that the combination of LIV with RANKL antibody is able to better preserve sublesional bone loss after SCI is also a novel finding, providing a groundwork for the future development of clinical protocols based on activity-based (e.g., LIV) and pharmacological (e.g., RANKL inhibitor) approaches to treat osteoporosis after SCI or other conditions associated with severe immobilization, with a goal to identify more effective and safer therapeutic approaches.

SAT-565

Bone Structure and Turnover in Postmenopausal Women with Long-Standing Type 1 Diabetes *Viral Shah[1], Shijing Qui[2], Jason Stoneback[3], Lubna Qamar[1], Virginia Ferguson[3], Wendy kohrt[3], Janet Snell-Bergeon[1], Sudhaker Rao[2]. [1]Barbara Davis Center for Diabetes, United States. [2]Henry Ford Hospital, United States. [3]University of Colorado, United States

Purpose: Fracture risk in people with type 1 diabetes (T1D) is increased 2- to 6-fold and may be related to compromised bone quality. We investigated bone histomorphometry in postmenopausal women with T1D and controls without diabetes using a tetracycline double-labeled trans-iliac bone biopsy.Methods: Postmenopausal women with T1D of at least 10 years and women without diabetes were studied to evaluate effects of T1D on bone structural and mechanical properties. After in vivo tetracycline double labeling, participants underwent trans-iliac bone biopsy. An expert (Dr. Qui) who was blinded to study group performed histomorphometry. Static and dynamic histomorphometry measurements were performed and compared between the two groups using Student's -test.Results: The analysis included postmenopausal women with T1D (n=9, mean age 58.4+/-7.1y with 37.9+/-10.9 y of diabetes, and HbA1c 7.1+/-0.4%) and postmenopausal women without diabetes (n=7, mean age 60.9+/-3.3 y and HbA1c 5.4+/-0.2%). There were no significant differences in menopause duration (11.6+/-9.8y vs 8.0+/-5.5 y) or serum PTH (38.6+/-8.1 vs 51.9+/-23.9 pg/mL), CTX 90.4+/-0.2 vs 0.51+/-0.34 ng/mL) or P1NP (64.5+/-26.2 vs 87.3+/-45.3 ng/mL) . Serum 25 (OH) D levels were higher in T1D than controls (53.1+/-20.8 vs 30.9+/-8.2, p<0.05). 75% of T1D participants reported fractures compared to 42.9% in controls. Bone volume, trabecular thickness and cortical thickness were similar between the groups but indices of bone formation and remodeling were non-significantly lower in T1D (Table). Conclusion: Long-standing T1D may affect bone turnover, mainly bone formation, without affecting bone structure. The findings of our study are similar to previous study suggesting T1D is a disease of low bone turnover. Non-significant differences may reflect inadequate statistical power. Further research is needed to understand bone turnover and factors affecting bone turnover in people with T1D.

Table: Differences in bone turnover between postmenopausal women with T1D and without diabetes.

Variables	With T1DM (N=9)	Without T1DM (n=7)	Percent difference (T1D versus controls)#
Bone volume (BV/TV)	17.2±4.6	15.5±2.6	+10%
Trabecular thickness (Tb.Th)	111.4±25.0	103.7±4.9	+7%
Cortical thickness (Ct.Th)	1.60±0.64	1.60±0.39	0%
Osteoid surface (OS/BS)	5.93±3.54	8.44±6.22	-30%
Osteoblast surface (Ob.s/BS)	1.31±0.60	1.94±2.34	-32%
Mineralized surface (MS/BS)	2.71±1.24	4.67±3.56	-42%
Bone formation rate (BFRs)	6.13±2.95	9.66±7.40	-37%
Activation frequency (Ac.f)	0.20±0.08	0.32±0.25	-37%

#Unadjusted, age- and menopausal duration-adjusted differences remained non-significant between groups.

Introduction: Patients with type 2 diabetes (T2DM) have an increased risk of bone fractures compared with non-diabetic controls (doi: 10.3390/jcm11082206). However, areal bone mineral density (aBMD) is increased in these subjects (doi: 10.1001/jama.2011.715) and it could not use as bone fragility predictor. Studies using HR-pQCT techniques has reported an increased cortical porosity in patients with T2DM (doi: 10.1530/EJE-15-0860). However, pQCT images involve a higher radiation and cost than DXA images. 3D-DXA allow cortical and trabecular volumetric parameters assessment from routine DXA. The aim of this study is to evaluate if any 3D-DXA parameter could be used as bone fragility predictor in T2DM.Methods: This case-control study included 91 T2DM patients (40F, 51M) and 135 non-diabetic controls (67F, 68M). 3D-DXA analysis was performed using hip DXA scans and 3D-Shaper software (v2.12, 3D-Shaper Medical, Spain). Differences in aBMD and 3D-DXA parameters between T2DM patients and controls were assessed using Student's t-test.Results: aBMD was significantly higher in the T2DM group compared to controls at total hip (13.2%, p<0.001) and femoral neck (12.0%, p<0.001). 3D-DXA parameters were also higher in the T2DM group compared to controls at total hip (11.2% for integral vBMD, 12.3% for trabecular vBMD, 5.7% for cortical vBMD, 6.3% for cortical thickness and 12.2% for cortical surface BMD, all p<0.001). No differences were found in integral and trabecular vBMD at the neck (p=0.175 and p=0.169, respectively). Cortical thickness at the neck was lower in the T2DM group compared to controls, although the difference was not statistically significant (-2.3%, p=0.174). Cortical thickness at the superior aspect of the neck was lower in the T2DM group compared to controls (-5.9%, p=0.007), as shown by the regions in yellow in the figure.Conclusions: aBMD and 3D-DXA parameters at total hip were higher for T2DM patients than for non-diabetic controls. However, patients with T2DM had significantly lower cortical thickness at the superior aspect of the femoral neck, which could potentially explain the increased risk of femoral neck fractures in this population. Future longitudinal studies are required to confirm this finding.

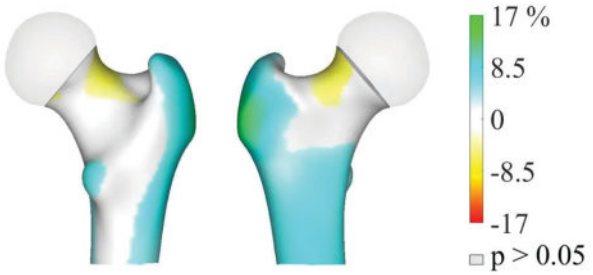

Figure 1: Distribution of the average differences (p<0.05) in cortical thickness between the T2DM group (n=91) and controls (n=135). Regions with non-significant changes (p>0.05) are shown in grey.

Association of Advanced Glycation End-products with Bone and Muscle Parameters in Obese Individuals With and Without Diabetes *Laurel Walfish[6], Claudie Berger[2], Michelle Wall[3], ANNE-FREDERIQUE TURCOTTE[4], MAHDI HOSSEINITABATABAEI[5], Bettina Willie[6], Fabrice Mac-Way[7], Claudia Gagnon[8], Suzanne Morin[6, 6]McGill University, [2]Research Institute of the McGill University Health Center, Canada, [3]Research Institute of the McGill University Health Centre, Canada, [4], [5]Shriners Hospital for Children, McGill University, [6]McGill University, Canada, [7]L Hotel-Dieu de Quebec, Canada, [8]CHU de Quebec, Universite Laval, Canada

Purpose: Obesity and Type 2 Diabetes Mellitus (T2DM) are associated with poor muscle and bone health. Tissue accumulation of advanced glycation end-products (AGEs) is associated with fractures and decreased muscle strength. We characterized the association between skin AGEs and bone and muscle parameters in adults with obesity, with and without T2DM.Methods: We analyzed baseline data from adults with obesity (body mass index [BMI] >=35kg/m2) participating in a multicenter observational cohort study on the effect of bariatric surgery on bone and muscle health. Skin AGEs, expressed in arbitrary units (AU), were measured by autofluorescence using the AGE Reader (Diagnoptics, UK). We measured total hip trabecular volumetric bone mineral density (vBMD), femoral neck (FN) cross-sectional moment of inertia (CSMI), FN maximal Z-scores and quadriceps muscle cross sectional area (CSA) by quantitative computed tomography, and isokinetic muscle force by dynamometer. Linear regression was used to determine the association between AGEs and the bone and muscle parameters. Covariables included sex, age, T2DM, BMI and percent predicted six-minute walking distance.Results: We included 69 participants (48 females, mean age 45 [SD 10] years) with a mean BMI 42 (SD 4) kg/m2. Twenty-nine (42.0%) participants had a diagnosis of T2DM (mean A1C 7.1 [SD 1.4] %) with a median disease duration of 2 years (interquartile range 1 to 9). Participants with T2DM were significantly older (50 [SD 6] years vs 42 [SD 11] years) and had higher AGEs (2.10 [SD 0.43] AU vs 1.86 [SD 0.47] AU). In the non-adjusted linear regression models (estimates [95% confidence interval]), AGEs were significantly associated with total hip trabecular vBMD (-6.8mg/cm3 [-12.0; -1.7] for each SD AU increase) (Table). When adjusting for T2DM, results remained significant (-5.7mg/cm3 [-11.0; -0.5] for each SD AU increase), but not after adjusting for age. Inclusion of other covariables did not change the estimate. Interactions of sex and T2DM with AGEs were non-significant. There was no association of AGEs with CSMI, maximal Z-scores, CSA or muscle force.Conclusion: Skin AGEs were negatively associated with total hip trabecular vBMD independent of diabetes status in adults with obesity. This association was no longer significant after adjusting for age. There was no association between AGEs and the other measures of bone and muscle parameters, possibly a reflection of our sample size or short duration of diabetes.

Table Unadjusted and adjusted estimates with 95% confidence interval of total hip trabecular vBMD, CSMI, max Z, CSA and Muscle Force for AGEs per 1 SD (0.5 arbitrary units)

Models	Total hip trabecular vBMD (mg/cm^3)	FN CSMI (cm^4)	FN Max Z (cm^3)	Quadriceps CSA (cm^2)	Muscle Force (Newton-Meter)
Unadjusted	**-6.8 (-12.0; -1.7)**	-0.05 (-0.32; 0.21)	-0.045 (-0.150; 0.060)	0.6 (-7.2; 8.4)	-17.8 (-36.9; 1.3)

Bone Deficits Pertain to the Trabecular Bone in Children with Type 1 Diabetes: Sex and Maturity Matched Case-control Comparison *Yuwen Zheng[1], Munier Nour[2], James (J.D.) Johnston[3], Saija Kontulainen[1], [1]College of Kinesiology, University of Saskatchewan, Canada, [2]College of Medicine, University of Saskatchewan, Canada, [3]College of Engineering, University of Saskatchewan, Canada

Children with type 1 diabetes (T1D) are experiencing a higher risk of fracture, which may be linked to impaired bone development. Our purpose was to assess differences in imaged bone and muscle characteristics between children with T1D and typically developing children (TDC). We matched 56 children with T1D (mean age 11.9yrs, SD 2.1yrs) and 56 TDC (11.5yrs, 1.9yrs) by sex and maturity from 237 participants (6-17yrs, 66 T1D). We imaged the distal radius and tibia with high-resolution peripheral quantitative computed tomography (HR-pQCT) and the radius and tibia shaft bone and muscle with pQCT. We compared limb-specific bone macro- and micro-architecture, density, and estimated strength (stiffness and failure load), along with pQCT-imaged muscle properties (area, density) using MANCOVA. We identified covariates from between-group comparisons (t-tests) of height, body mass, physical activity score, and nutrition (protein, calcium, and vitamin D intakes); only physical activity score differed (14% lower in children with T1D, p=0.003). Bone outcomes differed between the groups (Pillai's trace = 0.736-0.792, p<0.001). Children with T1D had a 5% lower trabecular number and 7% higher separation at the distal radius while cortical and tissue mineral density as well as cortical thickness were 3-18% higher. Children with T1D had 9% lower trabecular thickness at the distal tibia. They also had 4-7% higher cortical density at shaft sites. Muscle density was 3% higher in children with T1D. Findings indicate that children with T1D had deficits in trabecular bone micro-architecture at the distal radius and tibia, while the distal radius cortex had higher density and thickness. Prospective, longitudinal data characterizing bone development in children with T1D vs. TDC, along with endocrine and lifestyle factors contributing to bone development, are warranted to clarify these seemingly contradictory cross-sectional observations.

Growth Hormone Treatment Associated with Increased Vertebral Body Height in Children with Muscular Dystrophy *Malinda Wu[1], Emely Loscalzo[2], Julia See[1], Sonum Bharill[1], Nazanin Yousefzadeh[1], Ethan Gough[1], Janet Crane[1], [1]Johns Hopkins University, United States, [2]Johns Hopkins University ,

Vertebral body reshaping is a phenomenon observed in some children after vertebral fractures (VF). The purpose of this study was to examine if treatment with growth hormone (GH), testosterone (T), and/or zoledronic acid (ZA) impact vertebral body height of children with muscular dystrophy.In this retrospective study, vertebral body heights were measured in patients with Duchenne muscular dystrophy (DMD) and severe Becker MD. All participants were on chronic glucocorticoids and had been referred to endocrinology for concerns of short stature, delayed puberty, and/or osteoporosis. Serial lateral spine X-rays were scored by Genant's grading of VF. Multi-variable linear regression models analyzed change in anterior, middle and posterior vertebral heights while on treatment with GH alone, T alone and ZA with GH and/or T compared to ZA alone.The 27 participants had >400 measures of vertebral height with 34 incident VF noted. Median enrollment age was 13.5 years; median follow-up was 2.3 years. Participants were treated with GH, T and/or ZA according to typical pediatric practice: subnormal growth velocity/short stature, delayed puberty, and clinically significant fractures with low bone density respectively. Most participants were still growing during the study.After adjustment for multiple testing across vertebrae positions, GH was associated with increased vertebral height, reaching statistical significance when used alone of middle height (2.65 mm, P=0.015) or in combination with ZA of posterior height (0.80 mm, P=0.027) relative to ZA alone. In contrast, T alone was associated with decreased vertebral height, reaching statistical significance only of anterior height (-2.70 mm, P=0.032) relative to ZA alone; T with ZA had no specific trend nor statistically significant change relative to ZA alone. Co-variates associated with slight increases in vertebral height included increased age at endocrine referral, follow-up time, and body mass index and decreases in total body less head bone mineral density height-adjusted Z-score. We also observed a previously undescribed phenomenon, where some VF simultaneously both improved and worsened, i.e. changing between wedge or concave VF shapes. This observation was not frequent enough for statistical analysis. Multi-center data, more participants and longer follow-up is needed to explore the association of ZA, GH, and T use on vertebral reshaping.

Long-term bone microarchitecture assessment in patients with pregnancy and lactation osteoporosis *maria belen zanchetta[1], lujan lucchini[2], maria florencia scioscia[3, 1]md, Argentina, [2]Universidad del Salvador, Argentina, [3]IDIM, Argentina

Introduction: Previously, we described a severe trabecular bone microarchitecture deterioration in women who suffered vertebral fractures in the last trimester of pregnancy and/or early postpartum (PLO). In this study, our aim was to evaluate long-term changes in bone microarchitecture and bone mineral density (BMD) in this cohort of patients.Materials and methods: Patients with PLO who consulted our institution between 2007 and 2020 were invited to participate. All of them received calcium and vitamin D (VD) supplementation and one received 2 doses of denosumab after the diagnosis. Bone microarchitecture by High-resolution peripheral quantitative computed tomography (HRpQCT) of distal radius (DR) and tibia (DT). Assessments were performed at baseline and then annually.Results: Since 2007, 14 patients consulted for PLO but only 6 were adherent to this long-term follow-up study. Mean age was 28 yo and follow-up time varied from 2 to 14 years. Most patients had no specific risk factors except for one who receive very high glucocorticoid doses for idiopathic

thrombocytopenia during pregnancy and 2 years later was diagnosed with premature ovarian failure. This patient was excluded from the final analysis, as an outlier. Patients had irregular compliance to calcium and vitamin D supplementation. Radius trabecular density after 12-14 months, increased significantly from baseline, mean 4.4 % (range: 0 - 26%). Trabecular thickness increased 20%. Distal tibia trabecular density after 12 -14 months improved significantly (7.1%), and trabecular thickness increased (6-47%). The last assessment (9 to 14 years later) showed a significant improvement in radius Dtrab mean 12% (11 - 26%) and less in tibia (See table 1). Trabecular thickness and number also improved significantly. Dcomp. increased 3.2 % after 12 months at DT and 2.2% at RD during long follow-up. Conclusion: Trabecular bone microarchitecture improved significantly during the first year and continued to improve and maintained after 9 to 14 years. The cortical compartment recovered, to a lesser extent. PLO patients might have impaired cortical bone microarchitecture before pregnancy, probably genetically determined, and that is why there is no significant long-term recovery.Scioscia MF, Vidal M, Sarli M, Guelman R, Danilowicz K, Mana D, Longobardi V, Zanchetta MB. Altered Bone Mass and Biomarkers in Young Individuals with Long-Duration (10 Years) Type 1 Diabetes *Diana Swolin-Eide[1], Auste Pundziute Lycka[2], Daniel Novak[2], Bjorn Andersson[3], Gun Forsander[2], Per Magnusson[4]. [1]Professor, MD, Sweden. [2]MD, PhD, Sweden. [3]PhD, Sweden. [4]Professor, Sweden

Objective: Diabetes increases worldwide and is the second most common chronic disease during childhood. It is associated with several complications such as increased fracture risk. This study was designed to investigate if individuals with long-duration type 1 diabetes (T1D) have decreased bone mass and how bone biomarkers reflect bone remodeling in relation to healthy matched controls.Methods: Fifty Swedish individuals, age 15.0-17.9 years, with a T1D duration, mean 10.6 +/-2.1 years were included. Their mean HbA1c since their diabetes diagnosis was 57+/-6 mmol/mol. Thus, these individuals had diabetes through the entire puberty and growth spurt. A well-matched control group according to age, gender and geography was recruited. Bone mass was assessed by dual-energy X-ray absorptiometry and peripheral quantitative computed tomography. Clinical follow-up data were retrieved from the NDR-SWEDIABKIDS registry.Results: The groups were well-matched since there were no differences between the groups regarding age, weight, height and BMI. Fourteen individuals (28%) with T1D had sustained 16 fractures, and 18 control subjects (36%) had 19 fractures before study start Total body less head (TBLH) aBMD and TBLH BMC were lower in T1D individuals in comparison with the control group. Lumbar spine L1-L4 BMD and BMC showed no differences between the groups. Trabecular density was reduced in T1D ($p=0.012$) in contrast to cortical density which was unchanged. SSI was unchanged between the groups. PTH, 25(OH) vitamin D, sclerostin, bioactive sclerostin and bone specific ALP were not different between the groups. However, individuals with T1D had reduced CTX levels ($p<0.001$) indicating altered bone resorption.Conclusions: Young individuals with long-duration T1D have altered trabecular bone density and decreased CTX levels already at early ages and before they reach their peak bone mass. Bone health is therefore important to monitor in pediatric diabetes care.

Semaglutide Does Not Increase Bone Formation In Adults With Increased Fracture Risk *Morten Hansen[2], Eva Wölfel[2], Niklas Jørgensen[3], Richard Eastell[4], Stinus Hansen[5], Morten Frost[2]. [2]Odense University Hospital, . [2]Odense University Hospital, Denmark. [3]Rigshospitalet, Denmark. [4]University of Sheffield, United Kingdom. [5]Hospital of South West Jutland, Denmark

Incretin hormone glucagon-like peptide 1 (GLP-1) receptor agonists (GLP-1Ras) such as liraglutide are commonly used to treat type 2 diabetes (T2D) and obesity. They increase the bone formation marker P-Procollagen type 1 N-terminal propeptide (P-PINP) in obese individuals and preserve bone mass in patients with T2D despite causing weight loss. We tested the effect of semaglutide, a GLP-1Ra, on bone formation in adults with increased fracture risk.In this placebo-controlled, double-blinded clinical trial conducted at two public hospitals in Denmark, adults with a total hip or lumbar spine T-score < -1.0 and/or history of low-energy fracture and without diabetes were randomized (1:1) to receive subcutaneous semaglutide 1.0 mg (or highest tolerated dose) or placebo once weekly for 52 weeks. The primary outcome was the effect of semaglutide compared to placebo on the mean percentage change from baseline to week 52 in P-PINP. Additional outcomes included changes from baseline to week 52 in the bone resorption marker P-Collagen type I cross-linked C-terminal telopeptide (P-CTX), areal bone mineral density (BMD) (by dual-energy X-ray absorptiometry (DXA)), volumetric BMD (vBMD) (by Xtreme computed tomography (CT) II), and bone material strength index (BMSi) at the tibia (by Osteoprobe).Sixty-four individuals (86% female) with a mean age of 63 years (SD 5.5) and BMI ranging from 21 to 39 kg/m2 were enrolled. There were no differences in age, sex, and BMI between groups at baseline. The effects of semaglutide compared to placebo as the differences in mean percentage changes from baseline to week 52 included a nonsignificant 17% increase in P-PINP ($p=0.19$) (Fig. 1). By contrast, P-CTX increased by 54.8% ($p=0.005$). Lumbar spine BMD decreased by 2.1% ($p=0.01$) and total hip BMD decreased by 2.6% ($p=0.001$). Tibial vBMD decreased by 1.5% ($p=0.003$). There were no differences in changes between groups in femoral neck BMD, radial vBMD, or BMSi. With semaglutide, the mean percentage change in body weight was a 9.4% decrease after 52 weeks ($p<0.001$), while there were no change with placebo (Fig. 1). There were no serious adverse events related to semaglutide treatment and no episodes of hypoglycaemia.In conclusions, semaglutide once weekly for 52 weeks was not associated with increased bone formation in adults with increased fracture risk. The bone loss was likely caused by the increase in bone resorption which resulted, in turn, from the loss of body weight.

Figure 1. Mean percentage change from baseline for the bone formation marker P-PINP (broken lines) and body weight (solid lines) for semaglutide (orange) and placebo (purple), respectively

Vitamin D Supplementation in Primary Hyperparathyroidism: Effects on 1,25(OH)2 Vitamin D and FGF23 levels *Sthefanie Giovana Pallone[1], Monique Nakayama Ohe[1], Livia Marcela dos Santos[1], Isabela Ohki Nacaguma[1], Ilda Sizue Kunii[1], Renata Elen Costa da Silva[1], Sergio Setsuo Maeda[1], Cynthia Maria Alvares Brandao[1], Jose Gilberto Henriques Vieira[1], Marise Lazaretti-Castro[1]. [1]UNIFESP-EPM, Brazil

Background: Primary hyperparathyroidism (PHPT) is a condition characterized by high levels of PTH in the presence of hypercalcemia, and vitamin D deficiency has been associated with more severe presentations. However, Vitamin D supplementation raises safety concerns. Our objective was to understand and monitor specific metabolomic alterations resulting from Vitamin D supplementation in individuals with and without PHPT.Materials and methods: Individuals with and without PHPT received 14,000 IU/week of oral vitamin D3 for 12 weeks. At baseline and endpoint, blood samples were collected to measure 1,25(OH)2vitamin D (1,25(OH)2D), intact FGF23 (FGF23), 25-hydroxyvitamin D (25OHD), PTH, total calcium (tCa) and other biochemical markers. The intact FGF23 was measured using an automated Diasorin LIAISON kit. The 1,25(OH)2D measurement was performed using liquid chromatography and mass spectrometry (LC-MS/MS).Results: 70 subjects with PHPT and

75 healthy individuals (nPHPT) were included at the baseline, and 55 PHPT and 64 nPHPT completed the 12-week protocol. At baseline tCa, PTH, 1,25(OH)2D, and FGF23 concentrations were significantly higher in PHTP, with no difference in 25OHD levels. After the intervention, the 25OHD levels increased significantly in both groups (PHPT: from 22.6.9+/-6.1 to 31.5+/-6.8; nPHPT: from 20.3+/-5.7 to 32.5+/-6.4 ng/mL, p<0.001); the FGF23 levels increased significantly in both groups (PHPT: from 47.9+/-27.1 to 76.3+/-33.3; nPHPT: from 40.5+/-13.9 to 59.8+/-19.8 pg/mL, p<0.001). 1,25(OH)2D levels decreased in both groups (PHPT: from 94.8+/-34.6 to 68.9+/-25.3; nPHPT: from 68.7+/-23.5 to 56.4+/-20.7 pg/mL, p<0.001). No changes in tCa were observed (PHPT: from 11.02+/-0.9 to 11.1+/-0.8; nPHPT: from 9.6+/-0.3 to 9.6+/-0.3 pg/mL, p=0.153), as the same for urinary calcium (p=0.534) and PTH measurements (p=0.516) in both groups. The reduction of 1,25(OH)2D was inversely correlated with the elevation of FGF23 in both groups (r=-0.302, p=0.028).Conclusion: The weekly administration of 14,000IU of Vitamin D3 was safe and the increase in 25OHD after the supplementation did not change the calcium and PTH levels in adults with and without PHPT. Furthermore, a paradoxical decrease in 1,25(OH)2D, associated with an increase in FGF23 levels, was observed in both groups, suggesting a possible mechanism in which FGF23 reduces the production of 1,25(OH)2D, protecting PHPT patients from hypercalcemia in face of vitamin D supplementation.

Correction of Cross-Sectional Geometry for Porosity Improves Prediction of Human Rib Structural Bending Response *Mary Cole[1], Yun-Seok Kang[1], Amanda Agnew[2]. [1]The Ohio State University, United States. [2]The Ohio State University, United States

Elderly populations are particularly vulnerable to morbidity and mortality following rib fracture. Previous work has shown that rib structural properties are best explained by simplified cross-sectional geometry adjacent to the fracture location, outperforming age, sex, body size, bone mineral density, and simple whole rib geometry. Although cross-sectional geometry treats the rib cortex as a solid object, it contains hundreds of voids representing intracortical pores. The objective of this study was to evaluate whether cross-sectional geometry explains more variance in rib structural properties when calculated on a cortex with pores removed, as opposed to a solid cortex. Mid-level thoracic ribs (n = 191) from an age series (22-108 years, mean = 57.6 +/- 20.2 years) were dynamically loaded to failure in a simplified bending scenario representing a frontal thoracic impact. Structural properties of force, displacement, stiffness, and energy were predicted using cross-sectional geometry calculated from a solid cortex and a porous cortex. Predictors were compared between quantifying all pores, cortical pores only, or trabecularized pores only. Multivariate models included co-variates of age, sex, and section location (anterior or midshaft). Force, stiffness, and yield displacement were best explained by porosity-corrected cortical shape or total area. Peak displacement and energy were more sensitive to age-associated endocortical trabecularization. Compared to the solid cortex, porous cortex cross-sectional geometry explained up to 8.4% more variation in univariate analysis of structural properties and up to 6.1% more variation in multivariate analysis. Except for yield displacement, the strongest multivariate models included porous cortex cross-sectional geometry (45.2-73.3%). The porous cortex also provided a significantly closer multivariate model fit than the solid cortex for yield force, peak displacement, stiffness, and energy, and an equivalent model fit for peak force and yield displacement. Pore morphometry was evaluated as an independent predictor set, including percent porosity, pore density, mean pore area, and pore spatial distribution. With no cross-sectional geometry, pore morphometry still explained moderate variation (37.6-57.4%) in all structural properties except yield displacement. Porosity improves prediction of rib structural properties by accounting for intracortical bone loss, more accurately measuring cortical area and distribution.

Bone size may mediate multiscale relationships with radius cortical porosity in mid-life women *RANDEE HUNTER[1], ERIN BIGELOW[2], Duncan Waanders[3], Todd Bredbenner[4], Karl Jepsen[3], Amanda Agnew[5]. [1]SKELETAL BIOLOGY RESEARCH LABORATORY, United States. [2]UNIVERSITY OF MICHIGAN, United States. [3]University of Michigan, United States. [4]University of Colorado Colorado Springs, United States. [5]The Ohio State University, United States

Growing evidence of the coordinated functional adaptation of bone suggests relationships between multiscale skeletal traits that dictate fracture risk and influence discrepancies in bone strength declines across individuals should be elucidated. The early indicators of subsequent pathological bone loss that likely exist in the radius are not well understood, particularly in mid-life women. Previous work has identified unique relationships between microstructural traits such as porosity and whole-bone geometry in male radii. Thus, the purpose of this study is to investigate the relationship between cortical porosity and whole-bone geometry in the radius of mid-life women representative of ages commensurate with the menopausal transition time period. Left radii of n=20 female post-mortem human subjects (PMHS) aged 40-65 years were imaged on a high-resolution nanoCT system and reconstructed at 8µm to assess multiscale skeletal traits. Cortical porosity was quantified at the 33% site as pore area (Po.Ar), pore number, and cortical pore score (CPS). Correlations were used to investigate the relationships between porosity (Po.Ar/Ct.Ar), pore density (Pore#/Ct.Ar), and CPS with respect to robustness (R; Tt.Ar/length), a measure of whole-bone geometry. There were no significant relationships between any measure of cortical porosity and robustness (p>0.4) for the whole sample; however porosity generally decreased with increasing R, while pore density and CPS increased. When rank-ordering robustness values and separating the sample into “slender” and “robust” radii, contradictory trends emerged between groups for pore density and CPS. Slender radii demonstrated a weak (R=-0.29) decrease in pore density with robustness while robust radii demonstrated a weak increase (R=0.23). A weak positive relationship between CPS and robustness was found for the entire sample (R=0.21) but varied by size category (slender R=0.08; robust R=-0.16). Despite previous evidence that wider male radii have greater CPS, 85% of females in this sample regardless of size category, fell within a CPS range of 11.5-82 mm4 without evidence of increased CPS in robust samples. These results suggest the coordination of multiscale traits may be mediated by bone size in mid-life women but requires a larger sample to investigate these trends. The implications for discrepancies in strength-age trajectories and subsequent fracture risk will be examined using dynamic mechanical testing in future work.

The Use of Clinical Photon Counting CT In Three Dimensional Joint Space Analysis of the Wrist *Jilmen Quintiens[1], Michael Kuczynski[2], Sarah Manske[2], Harry van Lenthe[1], Walter Coudyzer[3], MELISSA BEVERS[4], Joop Van Den Bergh[5]. [1]KU Leuven, Belgium. [2]University of Calgary, Canada. [3]University Hospital Gasthuisberg, Belgium. [4]VieCuri Medical Center, . [5]VieCuri MC Noord-Limburg and Maastricht UMC,

Joint diseases such as osteoarthritis (OA) and rheumatoid arthritis (RA) are typically diagnosed based on radiographs, with a semiquantitative scale based on observed bone erosion and joint space width (JSW) narrowing. This results in floor and ceiling effects, and a significant worsening of condition is required before it can be detected. Moreover, 2D radiographs suffer from overlapping features which confuse the JSW definition. 3D JSW analysis has the potential to improve diagnosis and monitor progression in OA and RA. Previous studies have successfully developed a consensus approach for 3D joint analysis using high-resolution peripheral quantitative computed tomography (HR-pQCT) [1]. Yet, this method is limited by exclusively considering finger joints and by relying on HR-pQCT, a device not easily accessible for clinical applications. This study extends the technique to different articulations of the wrist and performs the analysis with clinical Photon Counting CT (PCCT), which is expected to become widespread in the near future.Five cadaveric wrists were scanned with PCCT (NAEOTOM Alpha, voxel size 0.1 mm) and HR-pQCT (XtremeCT II, voxel size 0.061 mm). Identical full bone masks were delineated on both modalities using image registration. Using the bone masks as input, JS masks were calculated for the scapholunate (SL), capitolunate (CL), radiolunate (RaL), scaphotrapezotrapezoidal (STT) and trapeziometacarpal (TMC) joints. The size of the morphological operations was scaled from PCCT to HR-pQCT by ratio of voxel size, and 3D analysis was performed as described by Stok et al. [1], using the ORMIR_XCT Python package.Using HR-pQCT as the reference value, mean JSW calculations in PCCT showed a RMSE of 0.254 mm. Mean RMSE for minimal JSW was 0.441 mm, a larger relative error (Fig.1).Differences in results between PCCT and HR-pQCT may be partly attributed to pose differences between scanning modalities, which is impossible to correct for. These differences may affect minimal JSW more than mean JSW. For the TMC joint, two specimens showed JS narrowing which decreased minimal JSW values below the voxel size. Moreover, HR-pQCT scans showed stack misalignments in this joint, affecting the JS quantification. In spite of these limitations, these results show that JSW analysis can be extended to different articulating surfaces and imaging modalities with acceptable consistency.[1] Stok et al., Quant Imaging Med Surg 10(2): 314-325, 2020.

Impact of Ilex paraguariensis Consumption on Rats Offspring Bone Development and Tissue Properties *Natasha Sanz[1], Laureana Villarreal[1], Florencia Buiatti Fagalde[1], Lilian Plotkin[2], Lucas Brun[1]. [1]Bone Biology Laboratory, School of Medicine, National University of Rosario, Argentina. [2]Department of Anatomy, Cell Biology & Physiology, Indiana University School of Medicine, United States

Introduction: Ilex paraguariensis is the herbal species from which Yerba Mate (YM) is derived. It is daily consumed in South American countries as infusions called 'mate' and 'terere', an alternative to tea or coffee. YM leaves contain bioactive compounds like polyphenols and xanthines (mainly caffeine). Previous studies have shown a negative impact of high caffeine consumption on BMD and increased risk of fractures in diets with low calcium intake. On the other hand, we have also observed positive effects of YM compounds on bone cells in vitro, and positive effect of YM infusions on BMD and trabecular bone biomechanical properties in vivo. Therefore, we aimed to evaluate in vivo effects of the YM exposure from embryonic stage up to youth, on bone development and tissue properties of rats. Methods: Ten-week-old Sprague-Dawley rats were divided into 3 groups: Controls consumed water ad libitum; YM group consumed an infusion prepared with 25 g of YM leaves in water at 70°C; YM+ group that consumed a YM infusion prepared with 50 g of YM in water at 90°C. After 30 days old, the rats were euthanized, and their bones were collected. The morphometry measurements were made using Image J 1.40 (NIH, USA) on digitalized radiographs of mandible and tibia bones and on cross sectional photos of femur diaphysis. On mandible, we measure its length (from the most anterior inferior bone point to the condyle), the mandibular area, the height of the jaw and the height of the molars. For femur measurements were total and bone marrow area, cortical thickness, endosteal and periosteal perimeter, internal and external diameter, width and length. For tibia measurements, we recorded the width and length. Three-point bending tests were performed on femurs and mandibles and the following parameters were collected: stiffness, ultimate load, failure load, absorbed energy and cross-sectional moments of inertia (CSMI, only in femur). Radiographs with calcium level patterns were taken, and BMD of tibias were obtained using Image J. All values are reported as mean+/-SD. Statistical tests were conducted using one-way ANOVA or Brown-Forsythe and Welch ANOVA for overall analysis. Only results with significant difference (*) vs control are shown in the Table. Conclusion: Evidence suggests that exposure to YM during the embryonic stage, weaning, and youth can cause changes in bone development and properties. Lower molar width, tibia diaphysis and femur cortical thickness were observed.

High Variabilities in Mouse Femur Strength Due to Specimen Malalignments and Testing Protocols *Ara Nazarian[1], Mason Garcia[2], Maria Buzo Mena[1], Isabella Stewart[1]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, United States. [2]Boston University, United States

PURPOSE: The 3-point and 4-point bending tests are the most prevalent methods used to determine the mechanical properties of bones in rodents. A study of 100 papers on wild-type mouse femur 3-point and 4-point bending tests reveals considerable variability in the reported mechanical indices. Notably, reported Young's moduli differed by 172% (1.3-17.4 GPa) for 3-point bending and 120% (3.1-12.5) for 4-point bending. We hypothesized that such discrepancies result from variations in testing protocols and specimen malalignment. In this study, we investigate the sensitivity of Young's modulus of rodent femur to the angular orientation of the bone relative to 3- and 4-point bending support and loading pins using finite element analysis (FEA). METHODS: Micro-CT imaging of a 15-week-old wild-type male mouse femur was used to create a 3-dimensional model in Mimics (v21.0; Materialize, Belgium) with appropriate smoothing and thresholding. A hydroxyapatite phantom was used to assign heterogeneous properties to the bone by converting bone attenuation to density, with subsequent density conversion to Young's modulus and a Poisson's ratio of 0.3 [1]. FEA was conducted in Abaqus (Dassault Systèmes, Inc., France). The load and support pins were made in Abaqus with a 2mm diameter and treated as rigid bodies. The support pin span was set at 8 mm, distributed equidistantly from the loading pin, which was placed in the center of the femur for 3-point bending. For 4-point bending, two loading pins were placed 1.3 mm away from the center of the bone, according to the literature. For both 3- and 4-point bending tests, displacement-controlled simulations at 1, 2, 3, and 4 mm of the loading pin(s) were used to determine stress and strain. Simulations were conducted in 5° increments from 0° to +/- 15° from the central axis, with the bones loaded in prone and supine positions, and Young's moduli were calculated from the slopes of the stress-strain curves. RESULT: Our simulations reveal that prone and supine 3-point bending tests with misalignments of up to 15° from the central axis resulted in 8.7% to 132.1% variation in Young's moduli. The 4-point variations were from 3.4% to 33.5% IMPACT: Minor malalignments in bone orientation, an artifact of testing, result in significant variations in 3- and 4-point testing results. Standardizations in testing apparatus and protocols are warranted for more comparable results. REFERENCES: [1] Morgan, E. F., et al. 2003

Transmembrane Protein 53 (TMEM53) Gene Deactivation Underlies Craniotubular Dysplasia (OMIM # 619727) *Michael P. Whyte[1], Robert S. Weinstein[2], Paul H. Phillips[3], Rongsheng Cai[3], G. Bradley Schaefer[3], Michelle A. Hutchinson[3], Gary S. Gottesman[1], William H. McAlister[4], Shenghui Duan[5], Steven Mumm[1]. [1]Shriners Hospitals for Children - St. Louis & Div. Bone & Mineral Diseases, Washington University School of Medicine, United States. [2]Division of Endocrinology, Metabolic Bone Diseases University of Arkansas for Medical Sciences, United States. [3]Arkansas Children's Hospital, United States. [4]Mallinckrodt Institute of Radiology at Children's Hospital, Washington University School of Medicine, United States. [5]Div. Bone & Mineral Diseases, Washington University School of Medicine, United States

Craniotubular dysplasia (OMIM # 619727) denotes the disorder, elegantly reported in 2021 from investigation of four Indian families, caused by a homozygous 4-base exonic insertion or a homozygous small deletion at the exon 2 splice acceptor site within TMEM53. TMEM53 encodes nuclear envelope transmembrane protein 53 involved in BMP-SMAD signaling (*OMIM 619722). We detail the generalized skeletal disorder of a 13-year-old American boy referred in 2018 for progressive vision and hearing loss due to cranial foramina encroachment by bone and associated with compound heterozygosity for a deletion and a missense defect within TMEM53. Steroid therapy for 6 months was ineffective, whereas optic nerve decompressions by curettage of soft overgrown vascular bone improved his vision. Radiographic skeletal survey showed bone tissue accumulation at his skull base, but generalized osteopenia elsewhere. His calvarium and facial bones were widened whereas his optic, auditory, and spinal canals were narrowed. DXA bone density was normal for the whole body assessment, but low in his spine and hip. Biochemical studies of mineral metabolism were unremarkable and bone turnover markers indicated active bone formation. Tetracycline-labeled iliac crest histomorphometry revealed abundant widely spaced "double labels" consistent with twice the expected rate of bone formation. Then, vision loss did not progress during prednisone and zoledronate treatment. Next generation sequencing of a panel of 35 genes underlying high bone turnover or high bone mass was negative. Trio whole genome sequencing subsequently identified in TMEM53: i) a paternally inherited heterozygous 54-base deletion, including the mRNA splice acceptor site for exon 2, and 31 bases of exonic sequence (c. 62-23_92), and ii) a maternally inherited extremely rare, in gnomAD (frequency = 0.000036), heterozygous missense variant (c.650C>T, p.Ser217Leu). In silico missense prediction models, SIFT and Mutation Taster, scored this variant as damaging. Ser217 is highly conserved across species. Thus, bi-allelic deactivation of TMEM53 causes

what is classified as a sclerosing bone disorder, “craniotubular dysplasia.” We find generalized features of poor bone quality and propose “TMEM53-associated skeletal disease”.

Muscle-derived FGF21 may negatively regulate bone homeostasis in DMD via promoting bone marrow adiposity *Katsuhiro Murakami[1], Jessica Li[1], Fang Guo[1], Chen Chen[1], Ling Wang[2], Hongshuai Li[1]. [1]University of Iowa, United States, [2]The University of Iowa,

Duchenne Muscular Dystrophy (DMD) is the most common muscular dystrophy seen in children which affects both muscle and bone. Poor bone health is a significant problem for DMD patients which concomitantly contributes to progressively reduced mobility and low quality of life. To date, the pathogenesis of bone abnormalities in DMD is still poorly understood and effective therapies to treat poor bone health in DMD are still lacking. We have previously identified a novel myokine, fibroblast growth factor 21 (FGF21), typically not expressed in skeletal muscle under physiological conditions, is dramatically upregulated in skeletal muscles in DMD mouse models. Systemic neutralization of circulating FGF21 significantly improved bone quality in dystrophic mice. However, how dystrophic muscle-derived FGF21 contributes to the disease progression in DMD, specifically to the poor bone health, has yet to be fully understood. In the current study, we found that rFGF21 treatment significantly increased bone marrow mesenchymal stem cell (BMSCs) adipogenesis and concomintely inhibted osteogenesis; Knockdown of beta-klotho (KLB, an obligate co-receptor of FGF21) using siRNAs blocked the effects of FGF21 on promoting adipogenic differention of BMSCs. Our data demonstrate that FGF21 directly regulats BMSCs differentiation favoring adipogenesis. We further tested in vivo whether elevated FGF21 increases bone marrow adiposity in DMD. We used osmium tetroxide staining with microCT to visualize and quantify bone marrow adipose tissue (BMAT) in tibia of dystrophic mice. Significantly increased bone marrow adiposity was observed in dystrophic mice when compared with WT mice. Excitingly, significantly reduced bone marrow adiposity along with improved bone mass and bone microstructure were observed in muscle conditional FGF21 KO dystrophic mice when compared with their dystrophic loxP controls. Our observations suggest an important role of muscle-derived FGF21 in regulating bone marrow adiposity and affecting bone homeostasis in DMD.

Bone Loss caused by Adjacent Intervertebral Injury is Blunted by the Ablation of RAGE *Remy Walk[3], KAITLYN BROZ[2], Munish Gupta[3], Simon Tang[4]. [3]Washington University in St. Louis, , [2], , [3]Washington University in St. Louis, United States, [4]Washington University in St Louis, United States

Intervertebral disc (IVD) injury leads to degeneration and inflammation. Needle puncture is a standard animal model to study IVD degeneration. Here, we evaluate the vertebral endplate response. The endplates provide transport to and from the IVD and maintain the structural integrity of the vertebra; the endplates may play a role in IVD degeneration and low back pain. The receptor for advanced glycation end-products (RAGE) is implicated in many inflammatory diseases and has been implicated in skeletal pathology. The objective was to assess vertebral endplate response following IVD injury and the role of RAGE signaling.All procedures were done with WUSM IACUC approval. CC4/5 and CC6/7 IVDs in C57BL/6 mice (n = 10/time point) and RAGE-/- (n = 5/timepoint) were injured with a 30G bilateral puncture confirmed on X-Ray with adjacent IVDs as internal controls. Endplates were imaged on a vivaCT40 at 10µm prior to and following injury. A subset of the IVDs were immediately fixed in 4% PFA and paraffin embedded; 10 µm sections were stained with TRAP activity and Safranin-O/Fast Green. Vertebral endplates were segmented using a custom MATLAB GUI. Weighted averages of the endplates are reported. Paired 2-way ANOVAs were used to determine the effect of injury and time point in Prism 9.4.0.Bone loss was observed at 2 weeks and recovered by 12 weeks following injury in WT while IVD degeneration was sustained throughout. Decreased BV/TV was associated with osteoclast resorption followed by gradual bone formation. Image registration confirmed that the resorption and formation was occurring at the pores within the endplate. Osteoclast activity was correlated with IVD degeneration, suggesting that the degenerative process by the IVD may be driving osteoclast differentiation and subsequent bone resorption. With deletion of RAGE signaling, the endplates are protected from bone loss despite no changes to IVD degeneration.Endplate bone loss, associated with osteoclast resorption, following IVD injury occurs rapidly in the first 2 weeks and returns to baseline by 12 weeks while RAGE deletion prevents bone loss. Osteoclast activity may be a direct response to the inflammatory cascade created by the IVD. Vertebral endplate changes with IVD degeneration may play an important role in the development of low back pain. Future work will investigate whether RAGE inhibition protects the endplate from IVD injury induced changes.

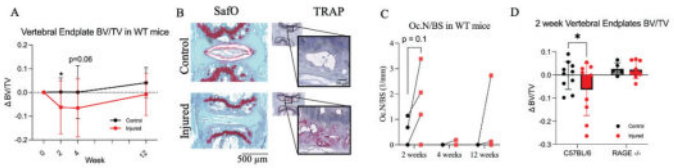

Figure 1: (A) Bone loss in WT vertebral endplates adjacent to an injured IVD was observed at 2 weeks following puncture with BV/TV returning to baseline by 12 weeks. (B) Safranin-O and TRAP stained adjacent sections from 2 weeks following injury demonstrate the correlation between IVD degeneration and osteoclast number. (C) Osteoclast number per bone surface (Oc.N/BS) is increased with injury (p = 0.05). (D) Bone loss is blunted in RAGE -/- mice.

Osteocalcin ameliorates cognitive dysfunctions in a mouse model of Alzheimer’s Disease by upregulating glycolysis in neuroglia *Chang Shan[1], Yuying Yang[1], Deng Zhang[1], Shengtian Li[2], Jianmin Liu[1]. [1]Ruijin Hospital, China, [2]Shanghai Jiao Tong University, China

Alzheimer’s disease (AD) is the most prevalent neurodegenerative disorder characterized by the build-up of amyloid ? peptides (A?) and impaired glucose metabolism in the brain. Osteocalcin (OCN), a protein derived from osteoblasts, has been found to influence brain functions, but its impact on AD remains uncertain. This study aimed to investigate the effects of daily intraperitoneal injections of OCN over a 4-week period on anxiety-like behaviors and cognitive impairments in a transgenic AD mouse model (APP/PS1). The results showed that OCN administration led to improvements in various behavioral tests: increased entries into the central area in the open field test, increased time and entries into open arms in the elevated plus maze test, increased time spent in the light chamber in the light-dark transition test, reduced escape latency, and increased preference for the target quadrant in the Morris water maze test. OCN treatment also ameliorated the accumulation of A? in the hippocampus and cortex of AD mice. Additionally, OCN enhanced the neural network function of the brain, particularly by increasing the power of the high gamma band in the medial prefrontal cortex of AD mice. Immunofluorescence analysis revealed that OCN inhibited the proliferation of astrocytes in the hippocampus of AD mice. Furthermore, OCN promoted glycolysis in astrocytes and microglia, as evidenced by increased glucose consumption, lactate production, and extracellular acidification rate. Notably, this effect was diminished when the OCN receptor, Gpr158, was knocked down in astrocytes. These findings highlight OCN as a potential novel therapeutic factor for AD, potentially through reducing A? accumulation and enhancing glycolysis in neuroglia.

Fractures and Mortality in Patients with Multiple Myeloma: A Nationwide Korean Case-Control Study *Jeonghoon Ha[1, 1], Republic of Korea

Background: Multiple myeloma (MM), a malignant hematologic disorder, profoundly impacts patients' bone health, heightening their susceptibility to pathologic fractures. These fractures compromise the quality of life and elevate mortality rates. This study examines the relationship between fractures and mortality rates in MM patients, shedding light on the subsequent impact on lifespan. Such an understanding aims to improve therapeutic decision-making, bolster patient outcomes, and potentially increase survival rates in the MM populations. Methods: In this population-based case-control study, data from 14,207 MM patients and age-, sex-, index date-, and comorbidity-matched healthy controls were analyzed in a 1:3 ratio using the Korean National Health Insurance Service database. Differences in mortality due to fractures following an MM diagnosis were compared across fracture sites for up to eight years. Results: Of the 14,207 MM patients, 1,193 (8.4%) experienced vertebral fractures (HR 2.210, 95% CI, 2.017-2.421), 202 (1.4%) had hip fractures (HR 2.502, 95% CI, 2.121-2.952), and 197 (1.4%) suffered upper limb fractures (HR 1.556, 95% CI, 1.343-1.801) during the observation period. The hazard ratios for mortality from any fracture, vertebral fracture, and hip fracture were 1.625 (95% CI, 1.423-1.856). 1.718 (95% CI, 1.481-1.993), and 2.040 (95% CI, 1.483-2.806), respectively (p<0.001 for all). Conclusion: This study establishes a significant correlation between fractures and increased mortality in MM patients. The findings underscore the urgent need for enhanced bone health management in MM patients to mitigate fracture risks and improve survival outcomes, offering critical insights for clinicians to formulate effective, personalized therapeutic strategies for MM patients.

Dementia medications, acetylcholinesterase inhibitors, reduce the risk of all fractures *Charles Inderjeeth[1], Emma Boland[2], Maxine Isbel[2], Diren-Che Inderjeeth[2]. [1]University of Western Australia & North Metropoitan Health Service, [2]SCGH, Australia

Background: Older people are at high risk of osteoporosis and dementia. We reported that in vitro and in vivo mouse models suggest that antidementia medications acetylcholinesterase inhibitors improve bone health through its impact on inhibiting osteoclasts and a potential anabolic effect on osteoblasts (Li, Xu, Inderjeeth et al, Journal Cellular Physiology 2023).Methods: In this aged care, dementia clinic, cohort study we follow-up 744 patients annually for 4 years. The main outcomes assessed were, incidence of new fracture and death. Data was entered into SPSS with analysis of frequency and comparison of groups using Chi-Square Test. Main analysis was demographics at baseline, diagnosis of dementia, prevalence of baseline osteoporosis and fracture, falls risk, dementia medications, osteoporosis medications and follow up incidence of fracture and mortality.Results: There were 744 patients followed up. At baseline fifty-nine percent were female and mean age 81 years (SD6.8). Twenty one percent had prior hip fracture Fifty six percent had dementia and 113 (15.2%) were on dementia medications. During 4 years of annual follow up 137(18%) reported new fractures. Overall mortality rate was 267/744 (36%). Patients with dementia were more likely to die (180/415 vs 87/329; p <0.001) with a trend to more fractures (73/415 vs 64/329; p = 0.078). Patients on dementia medications were less likely to fracture 15/113 vs 122/631 (p = 0.029). Conclusions: Patients with dementia have a higher risk of recurrent fractures and mortality. Treating dementia with Acetyl cholinesterase inhibitors appear to reduce the risk of all fractures. This clinical finding is consistent with our recently published in vitro and in vivo mouse model confirming the benefit of cholinesterase on bone histology, biology and biomarkers.

Risk factor	Fracture (1 year)	Fracture (4 years)	Deceased(1 year)	Deceased(4 year)
Dementia (yes)	26/299	73/415	27/415	180/415

Weight Loss Exacerbates Bone Loss in Women on Aromatase Inhibitors: A Study of Breast Cancer Survivors *Sandra Naaman, MD, PhD[1], Tamara Vokes, MD[2], John Cursio, PhD[2], Rajesh Jain, MD[2]. [1]Rush University Medical Center, United States, [2]University of Chicago, United States

Background: Breast cancer survivors on aromatase inhibitors (AI) experience abrupt and profound estrogen deprivation. Estrogen loss is associated with overall reductions in lean mass (LM) and redistribution of fat mass (FM), favoring the abdominal region, changes that may contribute to bone loss observed during AI therapy. Since women with breast cancer are frequently counseled to lose weight to reduce breast cancer recurrence risk, we investigated the association of changes in weight, LM, and FM with bone loss in black (B) and white (W) women on AI.Methods: Using a retrospective cohort design, we analyzed B and W females with hormone sensitive breast cancer on AI who completed baseline and follow up BMD's from 1 to 3 years apart. Excluded were patients who did not have both hip and spine BMD available or had metastatic breast cancer or primary hyperparathyroidism. Previously validated equations from our center were used to calculate FM and LM from spine and hip soft tissue measurements. Multivariate linear regression analyses were performed with BMD as the outcome and either weight change or FM and LM change as the predictor(s) in those who gained or lost weight, while controlling for age, race, and height. Results: In 45 subjects who received medications for osteoporosis, there was no significant decrease in BMD during AI therapy. The primary analysis included 153 women (70 B; 83 W) who had not received osteoporosis therapy. Compared to W, B were older (64.8 +/- 10.7 vs. 58.9 +/-9.2, p < 0.001); had higher BMI (30.9 +/- 5.9 kg/m2 vs. 28.2 +/- 6.0 kg/m2, p < 0.01) and higher BMD (lowest T-score -0.8 +/- 1.1 vs. 1.2 +/- 0.9, p<0.01). They also had higher FM (36.7 +/- 10.9 kg vs. 30.9 +/- 11.5 kg, p <0.01) and lower LM (39.8 +/- 5.7 kg vs. 42.0 +/- 5.1 kg, p < 0.02).Among 77 women who lost weight during the study, there was an association between weight loss and decreases in spine BMD (0.003 gm/cm2 decrease per 1 kg loss, figure 1) and total hip (TH) BMD (0.002 g/cm2 decrease per 1 kg loss), regardless of race or BMI. Loss of FM, but not LM, was significantly associated with a decrease in spine BMD (0.005 g/cm2 decrease per 1 kg loss, p=0.01) in these women. There were no significant changes in BMD in those with weight gain.Conclusions: Breast cancer survivors on AI who lost weight experienced greater BMD loss than those who gained weight, irrespective of race or baseline BMI, suggesting a need for close BMD monitoring and consideration for osteoporosis therapy.

Effects of Sleeve Gastrectomy on Bone Mass and Microarchitecture Differ By Sex and Menopausal Status *KARIN WU[4], Po-hung Wu[2], Galateia Kazakia[3], Sheena Patel[4], Dennis Black[5], Thomas Lang[3], Tiffany Kim[3], Nicole King[3], Hanling Chang[6], Gaia Linfield[7], Stanley Rogers[3], Jonathan Carter[3], Andrew Posselt[3], Anne Schafer[8], [4], United States, [2]University of California - San Francisco, , [3]University of California, San Francisco, United States, [4], , [5]UC San Francisco, , [6]Liberty University, United States, [7]New York Presbyterian-Weill Cornell Medical Center, United States, [8]University of California, San Francisco and the San Francisco VA Health Care System,

Laparoscopic sleeve gastrectomy (LSG) is a popular and effective treatment for obesity and related comorbidities. However, LSG has been shown to impair intestinal calcium absorption and negatively affect bone metabolism. Studies of skeletal effects have generally examined areal bone mineral density (aBMD) by dual-energy X-ray absorptiometry (DXA), but DXA may be biased in the setting of marked body composition changes and does not provide information about bone microarchitecture. Further, it is not known whether the skeletal impacts differ by sex and menopausal status. In this study, we examined the effect of LSG on aBMD and volumetric BMD (vBMD) and appendicular bone microarchitecture and estimated strength.A prospective cohort of adults (30 premenopausal women, 17 postmenopausal women, 8 men) with severe obesity (BMI 46 +/-7) underwent assessment of skeletal health by DXA, quantitative computed tomography (QCT), high-resolution peripheral QCT (HR-pQCT), and laboratory evaluation preoperatively and 6 and 12 months postoperatively (n=55 preoperatively and n=50 with at least one follow-up scan), although time to last follow-up was longer in some due to the COVID19 pandemic. Log-transformed linear mixed effect models were used to assess how bone parameters change with time after LSG, by sex and menopausal status. The fixed effect of the model was the interaction of time since LSG and sex and menopausal status, and the random effect was the individual participant.Mean 12-month weight loss was 35 kg. Overall median 12-month increase in serum c-telopeptide (CTx) was +87%, and in procollagen-1-N-propeptide (P1NP), +47% (both p<0.001). Predicted total hip aBMD by DXA decreased by 6.8% [95%CI -8.1 to -5.5%] over 12 months. The effect of time on total hip aBMD varied by sex and menopausal status, with a more rapid decline in postmenopausal women (by 7.3% over 12 months, p=0.01; Figure). Predicted spinal vBMD by QCT decreased by 3.4% in postmenopausal women over 12 months (p=0.01), while there was no significant change in spinal aBMD. Radial and tibial vBMD, trabecular bone volume fraction, and estimated strength by HR-pQCT declined, with significant interactions of time on postmenopausal women.In conclusion, axial and appendicular bone mass and microarchitecture decline after LSG, particularly among postmenopausal women. Targeted skeletal health screening and treatment may be warranted in postmenopausal women after LSG.

LB SAT-595

Influence of Human Dental Pulp Stem Cells Osteogenic Spheroids Secretome in the Immunomodulatory Potential on Macrophages *Katiucia Paiva[1], Gabriel Albuquerque-Silva[1], Daniel Barrozo-Ferreira[1], Niels Camara[2], [1]ry of Extracellular Matrix Biology and Cellular Interaction, Department of Anatomy, Institute of Biomedical Sciences, University of São Paulo, Brazil, [2]Department of Immunology, Institute of Biomedical Sciences, University of São Paulo, Brazil

In Bone Tissue Engineering, 3D culture models, such as spheroids, has gained more attention for enabling greater cell-cell and cell-extracellular matrix interactions and enhancing regenerative properties of mesenchymal stem cells. Among them, human adult dental pulp stem cells (DPSCs) have attractive properties for bone reconstruction. DPSCs secrete a wide range of biofactors that together are called secretome which can communicate with different cells, including macrophages (M?), being able to polarize them towards the M2/pro-regenerative phenotype that differs from the M1/proinflammatory. It is known that proinflammatory and hypoxic conditions affect the M? polarization. Thus, this project goal was to evaluate the DPSC spheroid secretome influence on M? polarization under an osteogenic, proinflammatory and hypoxic microenvironment. The single 500µm spheroid was formed by 5,5 x 104 DPSCs seeded on u-shape non-adherent 96 wells plates in a basic medium (BM). After spheroid compaction (3-days), differentiation was induced or not by osteogenic medium (OM) for 7 days under hypoxia (2% O2) or normoxia (20% O2). Then, spheroids were incubated or not with TNF-? for 2h and, then, conditioned media (CM) was carried out in an serum-free media for 2 more days. M? derived from THP-1 monocyte lineage were incubated with the spheroids CM for 2 days. M1 and M2 positive controls were induced by LPS and IFN-? or IL-4 and IL-10, respectively. The markers for M1 (IL-6, IL-12, IL-1B, TNF-a, TNFR1B, TIMP-1, CD80, CD96 and CD68) or M2 (IL-10, IL-13, TGF-B, CD200R, MMP-12 and TIMP-2) were evaluated by RT-qPCR analysis. Proinflammatory markers were more upregulated in M1 than M2. Inversely, antiinflammatory markers were upregulated in M2 than M1, except TIMP-2 and IL-10. M? incubated with CM-BM cultivated spheroids expressed more proinflammatory genes than those which was incubated with CM-OM spheroids, excepted TNF-a and IL-12. The same profile was observed for the antiinflammatory genes CD200R, TIMP-2 and MMP-12. M? incubated with CM-OM cultivated spheroids expressed more antiinflammatory genes than proinflammatory ones. Hypoxia microenvironment does not seem to affect the spheroid secretoma. Thus, our data suggest the pro-regenerative immunomodulatory potential of DPSCs spheroids secretome, and OM culture seems to be more important than hypoxia, increasing M2 polarization, even in a pro-inflammatory environment.

Bone Marrow Sinusoidal Endothelial Cells Show Fgf23 Upregulation in Murine Beta-Thalassemia and in Response to Direct Administration of Erythropoietin *JACKIE FRETZ[1], Xiuqi Li[1], Larisa Lozovatsky[1], Eileen Chua[1], Karin Finberg[1], [1]Yale School of Medicine, United States

Both iron deficiency and parenteral iron formulations can elevate circulating levels of fibroblast growth factor-23 (FGF23), a hormonal regulator of mineral metabolism classically thought to be produced primarily by osteocytes. Previously, using an Fgf23-eGFP knock-in reporter allele, we identified BM sinusoidal endothelial cells (BM-SEC) as a novel site of Fgf23 upregulation in iron-deficient Tmprss6-/- mice and in mice with phlebotomy-induced anemia. However, the stimuli inducing Fgf23 expression in BM-SEC remain unclear. Here, we used a heterozygous Fgf23-eGFP reporter allele to assess sites of Fgf23 upregulation in the Hbbth3/+ mouse model of non-transfusion dependent ?-thalassemia, which exhibits systemic iron loading and elevated circulating FGF23. Eight-week-old Hbbth3/+ mice showed expected anemia and splenomegaly, which were not altered by the Fgf23-eGFP allele. Anti-GFP immunohistochemistry detected greater Fgf23-eGFP reporter expression in BM-SEC of Hbbth3/+ mice versus Hbb+/+ controls. Fgf23-eGFP expression was also detected in the thymic vasculature but not vasculature of the liver, spleen, or kidney. These thalassemic mice showed a significant induction of circulating intact and c-terminal FGF23 in plasma. Furthermore, introduction of the Fgf23-eGFP allele created a noticeable dosage effect caused by heterozygous Fgf23 disruption. Because we detected both Fgf23 and erythropoietin receptor mRNA in wild-type murine BM-SEC by mining single cell RNA-Seq data from BM stromal populations (PMID: 31130381), and because our anemic mouse models with Fgf23-eGFP reporter expression in BM-SEC all show high serum erythropoietin (EPO), we examined if EPO could induce Fgf23-eGFP reporter expression in BM-SEC of mice with normal iron balance. Fgf23+/eGFP bone marrow plugs, gently flushed from long bones and treated with EPO ex vivo showed significant upregulation of green fluorescence compared to vehicle after 4 and 24 hours of treatment. Additionally, when animals were dosed with EPO for 6 hours, we detected more intense Fgf23 reporter expression in BM-SEC of Fgf23+/eGFP mice treated with EPO compared to saline. This was accompanied by an increase in plasma c-terminal FGF23 expression. Collectively, our studies expand the set of anemic states characterized by Fgf23 upregulation in BM-SEC to include ?-thalassemia and support a model in which EPO acts directly on BM-SEC to upregulate Fgf23 expression.

Addition of ATM Inhibitors to Radium223 Reduces Prostate Cancer Bone Metastases In Vivo *Diane Lefley[1], Callum Jones[1], Sarah Danson[1], Helen Bryant[1], Spencer Collis[1], Janet Brown[1], Penelope Ottewell[1], [1]University of Sheffield, United Kingdom

Rationale/Hypothesis:Bone metastases from prostate cancer are commonly treated with Radium223, and whilst initially effective, patients ultimately experience relapse. Radium223 causes DNA strand breaks within tumour cells that are in close proximity to the bone surface. We hypothesise that relapse is in part due to Radium223 induced activation of DNA damage response pathways, and that inhibition of DNA repair pathways with ATM inhibitors (ATMi) will increase the anti-tumour efficacy of Radium223 in bone.Methods:Male BALB/c nude or C57BL/6 mice received PC3 or RM1 cells, respectively, via intra-cardiac injection. 20mg/kg/day ATMi was administered on day 2, 7 or 10 and Radium223 treatment (50kBq/kg/week or 300kBq/kg/week) commenced 24 hours after first ATMi treatment. Tu-

mour burden was monitored by IVIS and effects on bone and immune cells were monitored by micro-CT, flow cytometry, and heam-analysis.Results:Radium 223 caused an increase in trabecular bone and reduced lymphocytes and monocytes in whole blood, which were not exacerbated with the addition of ATMi. 300kBq/kg Radium223 reduced PC3 tumours in bone by 86% compared with placebo. Addition of either ATMi AZD0156 or AZD1390 to 300KBq Radium223 further reduced bone metastasis by 98.3%. Furthermore, combining AZD1390 with a clinically relevant dose of Radium223 (50mg/kg) synergistically reduced tumour size in bone.Radium223 almost eliminated the growth of RM1 cells in bone when treatment started on day 2 (1.8x106 p/s for placebo vs 3x105 p/s for Radium223) and this effect remained when ATMi was added. Importantly, delaying treatment to mimic the treatment of established tumours (day 7) or large tumours in bone (day 10) resulted in synergistic anti-tumour effects when ATMi was added to Radium223 (tumour burden in bone = 6x104 p/s in placebo vs 1.8x104 p/s; day 10).ConclusionCombining Radium223 with ATMi is more effective at reducing bone metastasis compared with Radium223 alone in vivo.

Oncogenic FLT3 ITD and CD45/PTPRC Control Osteogenesis and Osteoclast Formation *Carolin Lossius[1], Anne Kresinsky[2], Akua Annoh[3], Martina Rauner[4], Lorenz Hofbauer[5], Joerg Mueller[6]. [1]Institute of Molecular Cell Biology, Center for Molecular Biomedicine (CMB), Jena University Hospital, Germany. [2]Research Group Waskow, Leibniz Institute on Aging - Fritz Lipmann Institute, Germany. [3]Division of Nephrology, University Hospital Dresden, Germany. [4]Medical Faculty of the TU Dresden, Germany. [5]TU Dresden University Medical Center, Germany. [6]Institute of Molecular Cell Biology, Center for Molecular Biomedicine (CMB), Jena University Hospital, , Germany

Activating mutations in the receptor tyrosine kinase FLT3 occur in 25 - 30 % of acute myeloid leukemia (AML) patients. In particular, internal tandem duplications (ITD) lead to oncogenic constitutive FLT3 ITD kinase activity with an altered signaling quality promoting leukemic cell transformation. The counteracting role of protein tyrosine phosphatase CD45 on FLT3 activity was demonstrated in vivo using Ptprc-/- mice in a FLT3 ITD knockin background. The inactivation of Ptprc in FLT3ITD/ITD mice resulted insevere hematopoietic phenotypes like leukocytosis, anemia and splenohepatomegaly (Kresinsky et al., Oncogene 2019).Surprisingly, 14-week-old male and female FLT3ITD/ITD Ptprc-/- mice also showed pronounced alterations in bone morphology and microarchitecture. Shortened bones, amorphous epiphyseal plates, high cortical porosity and reduced bone mineral density were observed. Increased trabecular structures were accompanied with severely reduced numbers of osteoclasts (OC), osteoblasts (OB), and virtually absence of adipocytes in the femoral trabecular bones of FLT3ITD/ITD Ptprc-/- mice.Ex vivo differentiation experiments showed reduced capacity in the formation of multinucleated OC of FLT3ITD/ITD Ptprc-/- mice. Their RNAseq data revealed impaired mRNA expression of bone resorption and OC differentiation markers like Oscar, Ocstamp, Dcstamp, Acp5, and Ctsk. Upregulation of proliferation markers and STAT5 target genes indicated pronounced FLT3 ITD signalling activities in the differentiated OC. Thus, oncogenic FLT3 ITD was found to drive proliferation of OC precursor cells, potentially at the expense to produce large, multinucleated OC.In contrast to OC, differentiation and mineralization capacity of FLT3ITD/ITD Ptprc-/- derived OB tended to be reduced compared to control animals. Here, downregulated expression of OB-markers Bmp5, Tgfb1, and Cxcl12 was observed. Further, suppression of adipocyte-related genes like Adipoq and Pparg might explain almost complete absence of adipocyte in situ. Taken together, the observed bone phenotype suggests a previously unnoticed role of FLT3 and CD45 in the formation of the hematopoietic niche and osteogenesis.

The Effects of the Nuclear Localization Sequence and C-Terminus of Parathyroid Hormone-Related Protein on the Growth Hormone-IGF-1 Axis *Thomas Rosol[1], Waleed Hashmi[1], Nathan Hoggard[1], Noriko Kantake[1], Megan Turner[1], shiyu yuan[1], Eason Hildreth[2]. [1]Ohio University, United States. [2]The University of Alabama, United States

Osteoarthritis (OA) is a progressive multifactorial joint disease characterized by the degeneration of articular cartilage. Up to now, OA is incurable and treatment options are very limited. Parathyroid hormone-related protein (PTHrP) plays an important role in the regulation of chondrocyte development. In bone, PTHrP acts as a downstream effector, regulating the rate and size of bone formation. PTHrP consists of an N-terminus, a mid-region, a nuclear localization sequence (NLS), and a C-terminus. PTHrP mediates intracrine actions through its NLS which translocates to the nucleus to act as a transcription factor for the regulation of genes involved in growth and metabolism. We intend to explore the cellular and molecular interaction of PTHrP with other factors including signaling molecules such as insulin-like growth factor (IGF-1) whose dysregulation leads to abnormal chondrocyte function and cartilage degeneration in OA. To study the function of NLS and C-terminus of PTHrP in vivo, we generated PTHrP ?/? mice (1-66) that lack the NLS and C-terminus of PTHrP. Pthrp ?/? mice showed stunted growth, altered skeletal development, and most die within 5 days after birth. Previous results show a decrease in IGF-1 levels in these mice, which could lead to defects in cartilage development. Histological analysis by Alcian blue staining and immunofluorescence shows a decrease in the expression of proteoglycans and type II collagen in chondrocytes isolated from Pthrp ?/? mice compared to the control. Overall, the NLS and C-terminus of PTHrP are essential for normal chondrocyte function and may be protective against articular cartilage degeneration.

A simple and minimal method for differentiation of chondrocytes from human dental pulp stem cells using a thienoindazole derivative small compound TD-198946 *Yuki KANNO[1], Yurika DANTSUJI[1], Monika NAKANO[1], Yuri MATSUI[1], Yoko Kawase-Koga[2]. [1]Department of Oral and Maxillofacial Surgery, Tokyo Women's Medical University, Japan. [2]Tokyo Women's Medical University, Japan

Human dental pulp stem cells (DPSCs) are now considered a type of mesenchymal stem cells and exhibit higher clonogenic and proliferative potential than bone marrow stem cells. Therefore, we hypothesized that human dental pulp stem cells, which have higher proliferative capacity than bone marrow mesenchymal stem cells, could be a new stem cell source for three-dimensional cartilage regeneration. Several studies have shown that a thienoindazole derivative small compound TD-198946 (TD) induces chondrogenic differentiation of mesenchymal cells. In our previous studies, we investigated whether chondrogenic differentiation could be enhanced by the use of TD in the currently known chondrogenic differentiation induction medium. the optimal concentration of TD was 10-7 M. Our previous chondrogenic medium is costly and complicated because it contains seven additives, including two growth factors. Therefore, we hypothesized that the benefits of TD could be maximized by simplifying the medium more. The aim of this study is to establish a highly efficient and low-cost method to induce DPSCs into chondrocytes as a cell source.DPSCs were obtained from dental pulp of premolars or third molars from 24 to 45-year-old patients and cultured in normal medium (NM, control) and chondrogenic medium with/without TD (C, C+TD) for 14-28 days. All procedures of the present experiments were approved by the ethics committee of the Tokyo Women's Medical University (ethics permission #2021-0039). Previous chondrogenic mediums were expensive and complex. Therefore, with reference to other reports, we decided to use a simple medium. This new chondrogenic differentiation medium consists ?-MEM with 5% FBS, 10 ng/mL transforming growth factor (TGF)-?1, 100 nmol/L dexamethasone, 6.25 ?g/mL insulin, 50 nmol/L ascorbic acid-2-phosphate, 110 mg/L pyruvate sodium.Real-Time Quantitative Reverse Transcription PCR (RT-qPCR) results showed that chondrogenic medium supplemented with TD (10-7M) most effectively increased gene expression levels of col2a1and aggrecan, that are chondrogenic differentiation markers. However, expression of sox-9 was not stable.The present results suggested that TD-induced DPSCs are a useful cell source for cartilage regenerative medicine. Furthermore, our new method successfully induced chondrocyte differentiation without the conventionally used bFGF. However, the results for sox-9 varied from cell line to cell line, suggesting that further studies, such as protein-level analysis, are needed.

TNXB regulates cartilage homeostasis in hemophilic arthropathy through AKT-mediated apoptosis *Qinghe Zeng[1], Jiali Chen[1], Xu Wang[1], Rui Xu[2], Weidong Wang[3], Yuliang Huang[3], Qi Sun[4], Wenhua Yuan[1], Pinger Wang[1], Shuaijie Lv[5], Peijian Tong[5], Hongting Jin[1]. [1]Institute of Orthopaedics and Traumatology, the First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China, China. [2]Department of Orthopedics, Affiliated Hospital of Jiangxi University of Traditional Chinese Medicine, Nanchang, China., China. [3]Department of Osteology, The Second Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China, China. [4]Department of Orthopaedic Surgery, Fuyang Orthopaedics and Traumatology Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, Zhejiang, China, China. [5]Department of Orthopaedic Surgery, the First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, Zhejiang, China, China

Recurrent joint bleeding in hemophilia patients frequently results in hemophilic arthropathy (HA). Drastic degradation of articular cartilage is major characteristic of HA, but its pathological mechanisms has not yet been clarified. DNA methylation is sensitive to environmental factors and likely involved in cartilage damage after hemophilic joint bleeding. Our genome-wide methylation analysis identidied 700 differentially methylated regions (DMRs) associated with HA. The DMR genes (DMGs) were significantly enriched

in extracellular matrix organization. Among these DMGs, Tenascin XB (TNXB) expression was down-regulated in human HA cartilages and in FVIII-KO mouse cartilages following joint bleeding. Further, TNXB knockdown enhanced catabolism and suppressed anabolism in primary chondrocytes. Importantly, the loss of TNXB in FVIII-KO mouse provides a disease-promoting role in HA by augmenting cartilage matrix degeneration and osteoporosis of subchondral bone. In addition, TNXB knockdown promote the chondrocyte apoptosis and inhibited the phosphorylation of Akt. However, AKT agonist dramatically suppressed Extracellular matrix (ECM) catabolism and apoptosis in TNXB-KO chondrocytes.In summary, our study demonstrated that TNXB is a central mediator of cartilage matrix degradation following joint bleeding, which functions by regulating the activation of AKT. These mechanistic insights allow targeted development of potentially new strategies for cartilage protection in HA.

Quantitative evaluation of osseous healing using bone mineral density in sagittal split ramus osteotomy. *Hayato Hamada[1,] Kotaro Kaneko[1,] Naoki Ikehata[1,] Yasuyuki Fujii[1,] On Hasegawa[1,] Daichi Chikazu[1,] [1]Tokyo Medical University , Japan

Introduction: Orthognathic surgery, such as Sagittal Split Ramus Osteotomy (SSRO), performed on patients with Ian deformities, is widely employed surgical procedure worldwide. SSRO allows for broad contact area between the divided bone segments, resulting in high postoperative stability and making it an applicability as an osteotomy technique. However, there have been no previous reports conducting a quantitative assessment of the osteogenic healing of the divide bone segments at the surgical site. Therefore, this study presents a quantitativ evaluation using bone mineral density to assess the osteogenic healing between bone segments after SSRO surgery.Materials and methods: The subjects were cases diagnosed with jaw deformities and underwent bilateral SSRO at the department of oral and maxillofacial surgery and orthodontics, Tokyo Medical University Hospital, between December 2021 and July 2022. The Obwegeser-Dal Pont technique was used for the surgical procedur, and bone fixation was performed titanium miniplate. Intermaxillary fixation was not applied postoperatively. Quantitative CT imaging was performed on the subjects at 1month preoperatively, 3 months, 6 months and 1 year postoperatively for evaluatio. Image analysis was conducted using SYNAPSE Vincent Ver.6.7.0003 (Fuji film Medical, Tokyo). Results: The subjects comprised 5 cases involving 10 sides (1 male, 4 females). The age at the time of surgery ranged from 21 to 36 years, with an average age of 26.8 years. Preoperative diagnosis included mandiblar prognathism in 4 cases and facial asymmetry in 1 case. The average BMD was as follows: Preoperatively; 561.4mg/cm3, 3 months postoperatively; 492.8mg/cm3, 6 months post operatively; 473.3mg/cm3, 1 year postoperatively; 476.9mg/cm3.Conclusion: The BMD between the divided bone segments after SSRO showed a decrease up to 6 months post operatively. However,there was no significant difference between the BMD at 6 months and 1 year postoperativly. The findings suggest that the osteogenic healing between the bone segments at 6 months and 1 yea postoperatively is nearly equivalen, indicating a stable bone healing process over time.

Anabolic Therapy for Treatment of Recurrent Fractures in a Young Patient with Rett Syndrome *Gina Woods[1,] Soumya Kurnool[2,] [1]University of California, San Diego, United States, [2]Endocrinology Fellow, United States

Background: Rett syndrome (RTT) is a rare neurodevelopmental disorder in women that is associated with osteopenia and a 4-fold higher risk of fractures.Patient Case: A 27-year-old ambulatory woman with RTT, osteoporosis, and catamenial seizure disorder presents with recurrent fractures after multiple falls. Initially, she received depot medroxyprogesterone acetate (DMPA) to control menstrual cycle-related seizures which was discontinued after navicular and clavicular fractures from falls. The patient then received two annual doses of zoledronic acid but developed multiple foot fractures after another fall. Subsequently, she was treated with abaloparatide for two years, during which she experienced no further fractures despite additional falls.A repeat DXA after 2 years of abaloparatide showed Z-scores of -2.1 (lumbar spine), -2.7 (R femoral neck), and -2.8 (L femoral neck). There was a statistically significant increase in BMD after anabolic therapy, with a 6.9% increase in the lumbar spine and 8% and 12.5% increases in the left and right femoral neck, respectively. As the patient's Z-scores remained low for her age, abaloparatide treatment was continued for another year.Conclusion: This case highlights the vulnerability of young women with RTT to early and severe osteoporosis. In a case report of 20 patients, DXA scans showed lower BMD in RTT patients compared to age-matched peers, potentially due to reduced bone formation. Ambulatory disability was also associated with a significant decrease in BMD in a 10-year longitudinal study. In this patient's case, her use of carbamazepine and previous treatment with DMPA were additional risk factors for osteopenia, as DMPA reduces ovulation and estrogen levels, resulting in lower BMD. The 2016 Clinical Guidelines for Management of Bone Health in RTT advise against using DMPA for hormonal intervention and recommend bisphosphonates for osteoporosis treatment but make no mention of anabolic agents. A case report of an 18-year-old nonambulatory patient with RTT on carbamazepine showed significant improvement in BMD and no further fractures after 8 months of teriparatide and 3 annual doses of neridronate. Therefore, in young RTT patients with osteoporosis, it is important to address risk factors such as nutritional deficiencies, monitor anticonvulsant use, avoid DMPA, and consider treatment with anabolic agents.

A giant parathyroid lesion with innumerable lytic lesions *Muhammad Faiz Muhamad[1,] Anne Mc Gowan[1,] [1]Tallaght University Hospital, Ireland

42 year old South-East Asian woman admitted with persistent vomiting on the background of 6 months history of lethargy, generalised aches and visibly large right sided neck mass. She is a non smoker with medical history of hypertension and hyperlipidaemia.Laboratory results revealed severe hypercalcaemia of 3.16mmol/L, phosphate of 0.91mmol/L, alkaline phosphate of 1338mmol/L and PTH of 1926pg/ml. The Vitamin D level was 31nmol/L, and urine calcium/creatinine ratio was elevated at 1.76mmol/mmol. The clinical diagnosis was made at this stage - severe primary hyperparathyroidism with raised suspicion of parathyroid carcinoma based on the presence of large neck mass and exceedingly high level of PTH(30 times upper limit).The Technetium-99 Sestamibi scan coupled with SPECT/CT neck confirmed the initial finding on the ultrasound of neck as it revealed intense uptake in the right neck mass which representing a giant parathyroid lesion. Osseous abnormalities were seen on the bone windows, concerning for skeletal changes of hyperparathyroidism. The whole nuclear body scan showed uniformly increased uptake affecting the entire skeleton, characterised as a superscan as there was diminished uptake by the kidneys. The SPECT-CT scan of pelvis confirmed the presence of innumerable lytic lesions consistent with Osteitis Fibrosa Cystica.The initial management included rigorous IV fluid, followed by IV bisphosphonates. A 44.9 grams measuring 6cm right parathyroid lesion was resected. Her postoperative course was complicated by development of hungry bone syndrome with prolonged HDU stay.The histology analysis reported a well circumscribed encapsulated lesion with no lymphovascular or perineural invasion or necrosis, suggestive of parathyroid adenoma. The genetic analysis for familial hyperparathyroidism including AIP, CASR, MEN1, CDKN1B and CDC73, was negative to identify a pathogenic variant.Additional results include elevated CTX-1, osteocalcin, P1NP and HCG. The elevation of HCG has been analysed as potential biomarker for parathyroid carcinoma in small studies .This case illustrates a severe skeletal manifestation of hyperparathyroidism caused by a large autonomous parathyroid lesion with underlying chronic vitamin D deficiency. WHO in the year of 2022 listed atypical parathyroid tumour as the third classification, to reflect its unknown potential of malignancy. This lady is under close observation due to concern of possible recurrence.

Recombinant human monoclonal antibody for fibroblast growth factor 23 (Burosumab, Crysvita®) treatment for FGF23-related hypophoshatemia in an adult patient with severe fibrous dysplasia in McCune-Albright syndrome. *Maria Stelmachowska-Bana?[1,] Karolina Cylke-Falkowska[2,] Wojciech Zgliczy?ski[1,] Waldemar Misiorowski[1,] [1]Department of Endocrinology, Centre of Postgraduate Medical Education, Poland, [2]I Department of Internal Medicine, Biela?ski Hospital, Poland

Background: McCune Albright syndrome (MAS) is a rare mosaic genetic disorder affecting 1/100 000 to 1/1000 000 of the population. It arises from a somatic gain-of-function mutation in GNAS gene. The clinical picture is complex and includes fibrous dysplasia (FD), café-au-lait spots, precocious puberty and other hyperactive endocrinopathies. The degree of FGF23 overproduction is correlated with FD severity, and frank hypophosphatemia occurs only in patients with extensive skeletal involvement, resulting in frequent fractures, pain, increased propensity for deformities, and muscle weakness. Burosumab is a monoclonal antibody that targets FGF23, indicated for the treatment of hypophosphatemic rickets caused by overproduction of FGF23 (XLH, TIO). To date, there is no evidence on the effectiveness and safety of burosumab treatment in adults with FD/MAS.Case presentation: A 27-year-old male with MAS was under the care of the Endocrinology Department for persistent hypophosphatemia despite treatment with oral phosphate supplements and alfacalcidol. MAS was diagnosed at the age of 6 years and his medical history included precocious puberty, multiple fractures, skeletal deformities, muscle weakness and exacerbated skeletal pain due to severe FD. The patient was diagnosed with GH excess at the age of 22 years and has been treated with pasireotide 40 mg every 4 weeks i.m. with normalization of IGF-1 level for age and sex. Because of persistent hypophosphatemia (serum phosphate 0.38 mmol/L) resulting from FGF23 excess (serum FGF23 495kRU/L), bone pain and frequent fractures, the treatment with burosumab has been attempted (1 mg/kg body weight s.c. every 4 weeks). Over the 6-month course of treatment, the patient reported improved general well-being, reduced bone pain and increased muscle strength. Normalization of serum phosphate, PTH and a significant reduction in alkaline phosphatase levels were achieved (serum phosphate 0.83mmol/L, alkaline phosphatase 618.8 IU/l, PTH 51.6 pmol/L). No adverse effects of the short-term therapy were observed.Conclusions: This is the first reported case of burosumab treatment in an adult patient with FGF23-related hypophosphatemia in MAS. In our case, positive effects of the therapy were observed, both in terms of the patient's reported well-being and in terms of calcium-phosphate balance and bone markers. However, a longer follow-up in a larger group of adult patients with MAS seems necessary.

Platelet-Rich Fibrin Accelerates Osteogenic differentiation of Human Dental Pulp Stem Cells *Yoko Kawase-Koga[1], Ayano Hatori[2], Eva Dohle[3], Yasuyuki Fujii[4], Yuki Kanno[1], Sarah AI-Maawi[3], Robert Sader[3], Daichi Chikazu[4], Shahram Ghanaati[3]. [1]Division of Maxillofacial Surgery and Stomatology, Department of Oral and Maxillofacial Surgery, Tokyo Women's Medical University , Japan. [2]Department of Oral Health and Diagnostic Sciences, School of Dental Medicine University of Connecticut Health, United States. [3]FORM, Frankfurt Oral Regenerative Medicine, Clinic for Maxillofacial and Plastic Surgery, Goethe University, Germany. [4]Department of Oral and Maxillofacial Surgery, Tokyo Medical University, Japan

[Background] Human dental pulp stem cells (hDPSCs) have demonstrated higher clonogenic and proliferative potentials than bone marrow stem cells and can be easily obtained from extracted teeth in minimally invasive surgeries without any ethical issues. Generally, the conventional culture methods for hDPSCs have used high concentrations (10-20%) serum, such as fetal bovine serum (FBS), to maintain cell viability. However, the use of animal components that are at risk of transmitting pathogens and immune responses to recipients must be considered for the clinical application of stem cell-based therapy. Platelet-rich fibrin (PRF) is a blood concentrate system derived from human peripheral blood obtained through centrifugation without the addition of anticoagulants or external chemicals. PRF performs biological processing of acellular biomaterials with autologous cells and growth factors by combining them with biomaterials to enhance and accelerate the regeneration process within the graft bed. The aim of this study was to evaluate the effectiveness of the PRF-conditioned medium (PRF-CM) compared to FBS general medium in promoting hDPSC proliferation and differentiation. [Methods & Results] Venous blood samples were obtained from 3 healthy donors and immediately centrifuged at medium speed 1200 rpm for 8 minutes. The obtained PRF was cultured for 2 weeks to prepare RPF-CM. hDPSCs were obtained from dental pulp of third molars from 26-31 years old patients and cultured with 15%PRF-CM or 15% FBS in general culture condition and in osteogenic condition. The cell proliferation assay indicated PRF-CM group exhibit lower cell numbers and proliferation rates compared to FBS group. Interestingly, Alizarin Red staining and von Kossa staining in PRF-CM group showed significantly higher calcification than the FBS group by quantification analysis. RT-PCR showed significantly higher expression levels of ALP, osteocalcin, type I collagen alpha 1, and RUNX2 in the PRF-CM group. [Conclusion] This study introduces the novel application of PRF-CM in enhancing the differentiation of hDPSCs, providing an alternative to FBS culture medium, and addressing concerns associated with the use of animal components in clinical settings.

The Therapeutic Effect of AAV9-lncR-APDC in Mitigating Periodontitis-Induced Bone Loss *Zoe (Xiaofang) Zhu[1], Jake Chen[1]. [1]Tufts University, United States

Periodontitis, a chronic inflammatory disease that is highly prevalent, triggers an excessive host immune response, leading to alveolar bone resorption and subsequent tooth loss. Our prior research demonstrated that the long noncoding RNA APDC (lncR-APDC) influences bone remodeling by enhancing osteogenesis and inhibiting osteoclastogenesis. The current study explores the role of lncR-APDC in periodontitis progression and therapy. Our experiment with a periodontitis (EP) animal model exhibited exacerbated bone loss and disrupted pro-inflammatory cytokine regulation in lncR-APDC knockout (KO) mice. Single-cell RNA sequencing of EP gingival tissue revealed changes in the proportion and function of epithelial cells and immune cells, including T and B cells, macrophages, and neutrophils due to LncR-APDC silencing. We discovered a new epithelial cell subset (Krt8+, Krt18+, Krt5-, Krt14-) in the lncR-APDC-KO group, which interacts with immune cells through multiple ligand-receptor pairs. Interestingly, the cell-cell communication between macrophages and other cell types, such as neutrophil, T cells and fibroblasts, were extremely active through Trem1/Pglyrp1/Il1 ? axis. The gene Tff2, which was significantly elevated in lncR-APDC KO bone and gingival tissues, has a predicted direct binding site on LncR-APDC. Furthermore, intra-gingival administration of AAV9-lncR-APDC demonstrated remarkable therapeutic effects on periodontitis by alleviating bone mass and inflammation. In conclusion, our results suggest that LncR-APDC plays a pivotal role in the epigenetic control of periodontitis pathogenesis and holds therapeutic potential for periodontitis.

Roles of osteoblast dopamine D2 receptor in type 1 diabetes-induced bone loss *YASER PEYMANFAR[1], Philip Trackman[2]. [1]Forsyth Institute/ Harvard School of Dental Medicine , United States. [2]The Forsyth Institute , United States

Poor bone health in diabetic patients increases the risk of bone fractures, loss of mobility and can be life threatening. Bone mineral density (BMD) in diabetic patients only partially determines bone strength while there is increasing evidence that the structural integrity of the organic phase of bone made up primarily of type 1 collagen is also important. Extracellular lysyl oxidase (LOX) catalyzes the oxidative deamination of hydroxylysine and lysine residues in collagen, and required for the formation of biosynthetic crosslinks and subsequent stability of functional collagen that ultimately increases bone strength. Lysyl oxidase-dependent cross-linking of bone collagen is deficient in type 1 diabetes, while regulation of lysyl oxidases in diabetes is under-studied. Previously, we have reported that downregulation of bone LOX occurs in type 1 diabetes and is associated with trabecular bone loss and poor collagen structure. Importantly, we have determined that gut-derived peripheral circulating dopamine in diabetic mice is abnormally elevated and is associated with LOX downregulation which in turn adversely affects collagen structure and bone strength. We have seen that blocking of dopamine D2 receptor (D2R) activity pharmacologically with the highly selective antagonist Amisulpride in type 1 diabetic mice rescued trabecular bone loss and partially rescued LOX expression levels in osteoblasts in type 1 diabetic mice.Since the systemic administration of Amisulpride may trigger secondary effects on metabolism and bone turnover, we generated a novel osteoblast-specific dopamine receptor 2 (D2R) knockout mouse using Col1-2.3-cre+/- and D2rfl/fl and control mice in the C57BL6/J background. Type 1 diabetes was induced by streptozotocin following standard protocols. Diabetes was confirmed by measuring blood glucose (glucose>300 mg/dl). Our hypothesis is that bones in osteoblast-specific conditional D2r knockout mice will be resistant to diabetes-induced pathology. Surprisingly but interestingly, our results exhibited a high degree of apparent embryonic lethality in homozygous KO mice. However, micro-CT data indicate that osteoblast heterozygous D2r knockout female mice exhibited femurs rescued from diabetic bone deficiency (n=8), and the same response observed in fewer male mice as well. We are investigating both the apparent embryonic lethality and mechanisms by which D2r regulates bone homeostasis.

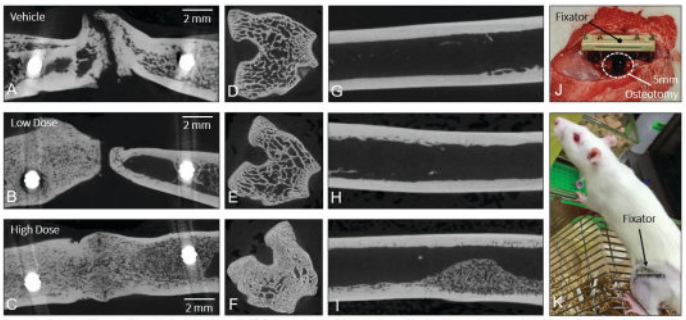
Effects of Systemically Administered Mes-1022, a Bone-Targeted EP4 Agonist, in Rats with a Critical-Size Femoral Segmental Defect *Jack Chapman[1,] Catherine Julien[1,] Mayumi Umebayashi[1,] Taylor deVet[1,] Michal Kulasek[1,] Aijing Shen[1,] Frank Rauch[2,] Bettina Willie[3.] [1]Co-Author, Canada[.] [2]Shriners Hospital for Children, Montreal, Canada[.] [3]McGill University, Canada

Introduction: Up to 5% of long bone fractures exhibit delayed healing or non-union. Mes-1022, a novel anabolic prodrug, has been shown to promote bone healing when applied locally, but it is unclear whether systemic administration enhances healing. We aimed to evaluate the effect of systemically-administered Mes-1022 on critical-sized bone defect healing and mass and microstructure of the intact contralateral femur.Methods: Ten-week-old female Sprague-Dawley rats (8/group) had a 5 mm osteotomy of the left femoral mid-shaft, stabilized by a unilateral external fixator (Fig 1J,K). Rats received weekly subcutaneous injections of Mes-1022 at 5 mg/kg (high dose), 1.7 mg/kg (low dose), or Vehicle (PBS + 25 nM EDTA). Serum markers and open field activity including rearing were measured pre-osteotomy and throughout study. Rats were sacrificed after 12 weeks and osteotomized and unoperated femora were imaged via micro-CT. Dissected intact femora underwent destructive three-point bending. Data were analyzed by ANOVA followed by post-hoc Tukey testing, with significance at $p < 0.05$.Results: Full bony bridging only occurred in 1 rat, which was treated with high dose Mes-1022 (Fig. 1A-C). At the osteotomy, high dose rats had higher tissue mineral density (TMD) of newly formed lower mineralized bone versus vehicle rats. For unoperated femurs, increased cortical area and max moment of inertia, as well as decreased TMD and medullary area were evident at the mid-diaphysis (Fig. 1G-I) of high dose versus low dose animals. Vehicle and low dose groups had lower porosity when compared to the high dose group. At the distal metaphysis (Fig 1D-F), high dose rats had higher trabecular number and thickness versus low dose rats. There was no difference in mechanical properties between groups. High dose treated rats had a higher rearing count at week 9 compared to low dose rats. P1NP was higher with high dose versus vehicle and low dose at week 1, and with high dose versus vehicle at week 6. TRAcP-5b was lower with high dose versus vehicle at week 10. Serum ALP did not differ between groups.Conclusion: High dose treatment with Mes-1022 enhanced cortical and trabecular microstructural parameters in the contralateral femur diaphysis by stimulating endocortical bone formation and initiating new trabeculae and (re)modeling of existing trabeculae. Histological analysis of callus tissue composition within the osteotomized femur is ongoing to determine if healing was enhanced.



Reconstructed microCT scans of the mid-diaphysis of operated (left) femurs in rats with most advanced healing from each group: vehicle (A), low dose (B), and high dose (C). Representative reconstructed microCT scans of metaphysis of intact (right) femurs for vehicle (D), low dose (E), and high dose (F) rats. Representative reconstructed microCT scans of diaphysis of intact (right) femora for vehicle (G), low dose (H), and high dose (I) rats. Higher-mineralized tissue (> 614 mg HA/cm³), termed quiescent bone, was distinguished from newly formed lower-mineralized tissue (287 - 614 mg HA/cm³) termed non-quiescent bone. External fixator on rat day 6 post-surgery (K), and immediately post implantation during surgery (J). Four titanium pins are threaded through a unilateral bar and then drilled into the femur. The 5 mm osteotomy is created with a gigli wire saw and saw guide.

LB SAT-610

Sclerostin but not Dickkopf-related protein 1 predicts bone mass and markers of bone turnover in older adults *MARILENA CHRISTODOULOU[1,] Terry Aspray[2,] Isabelle Piec[3,] WILLIAM FRASER[4,] Inez Schoenmakers[5.] [1]University of East Anglia, [2]Translational and Clinical Research Institute, United Kingdom[.] [3]BioAnalytical Facility, University of East Anglia, United Kingdom[.] [4]UNIVERSITY OF EAST ANGLIA, United Kingdom[.] [5]UEA, United Kingdom

Sclerostin (SOST) and Dickkopf-related protein 1 (DKK1) are antagonists of Wnt signalling and inhibit osteoblast activity and indirectly stimulate osteoclast activity. SOST and DKK1 antibody therapy leads to increases in bone mass and bone formation. However, reported associations between plasma SOST and DKK1 concentrations and measures of bone mass and turnover are conflicting.This study in healthy older men and women (n=379; median[IQR] 74.1 [71.5-77.0]y) investigated associations between plasma SOST and DKK1 and (a) BMD and BMC at the hip and femoral neck, (b) markers of bone turnover and Wnt signalling (C-terminal telopeptide (CTX), Procollagen 1 N-terminal Propeptide (P1NP), bone alkaline phosphatase (BAP), osteoprotegerin (OPG) and soluble receptor activator of nuclear factor ?-B ligand (sRANKL) and (c) hormonal regulators (parathyroid hormone (PTH), 1,25-dihydroxyvitamin D (1,25(OH)2D), 25 hydroxy vitamin D (25(OH) D), intact and c-terminal Fibroblast Growth Factor 23 (iFGF23, cFGF23) and KLOTHO). Associations were analysed by univariate (model 1) and multivariate linear regression with adjustment for height, weight and age (model 2) or renal function (CKD-EPI eGFR; model 3).Plasma SOST was significantly, positively associated with BMD and BMC at both sites (all $P<0.001$) and negatively with CTX, P1NP and BAP (all $P<0.01$). Associations of SOST with DKK1, OPG and RANKL were non-significant. SOST was negatively associated with 1,25(OH)2D ($P=0.002$) and positively with cFGF23 and iFGF23 ($P<0.001$ and 0.025). Associations with PTH, 25(OH)D and KLOTHO were non-significant. Multivariate model 2 provided similar results. Adjustment for eGFR attenuated associations with 1,25(OH)2D ($p=0.06$) and iFGF23 ($p=0.07$).Plasma DKK1 was negatively associated only with cFGF23 in univariate and both multivariate models.In conclusion, plasma SOST but not DKK1 was positively associated with bone mass and negatively with markers of both bone formation and resorption, suggestive of a lower rate of bone remodelling. This was independent of body size and renal function.

Physiologic Load Induced Strain of 3D Printed Truss Element Amplifies Osteogenic Response of Human Mesenchymal Stem Cells Compared To Static Surface Feature Influence *Ali Kiapour[1,] Se-Hwan Lee[2,] Brendan Stoeckl[2,] Lewis Harrison[3,] Jessee Hunt[4,] Robert Mauck[2,] Su-Jin Heo[2.] [1]Department of Neurosurgery, Massachusetts General Hospital Harvard Medical School, United States[.] [2]University of Pennsylvania, United States[.] [3]4WEB Medical Inc., United States[.] [4]4WEB MEDICAL Inc., United States

INTRODUCTION:Proprietary build themes have been developed to create a hierarchical surface roughness on a Ti truss-based implant using Electron Beam Melting (EBM) technology. This study evaluated how surface features influence MSC morphology, adhesion, clustering, and osteogenic differentiation. We also assessed the amplification effect of dynamic physiologic load-induced strain of a truss element on the osteogenic response of human MSCs beyond the baseline differentiation initiated by static surface technology. METHODS:Three different hierarchical surface roughnesses were fabricated using EBM:1) Smooth Titanium (Smooth), and two proprietary 3D-printed (P3D) titanium surfaces, which consist of a hierarchical surface roughness that spans from the macro to nano-scale having lesser 2) P3D1 or greater 3) P3D2 surface roughness. Human bone marrow-derived MSCs (hMSCs) were obtained, and passage two cells (5×10e5 cells) were seeded onto P3D2 surfaces (10mm×60 mm). A custom bioreactor system was designed to apply 3-point bending

to hMSC-seeded P3D2 surfaces [35µm of cyclic deformation, 1Hz, one time (DL×1), twice (DL×2), or 3 times (DL×3) in daily 3-hour cyclic loading increments on day 1, 2, and 3; Fig.1C] in basal cell growth media]. The Live/Dead assay and RT-PCR were performed after the first dynamic loading.RESULTS:3D scan images (Fig.1A) showed non-uniform 3D peaks and valleys on the P3D1 and P3D2. The areal method analysis showed that P3D1, and P3D2 had similar surface roughness, and the height distribution of P3D2 was sharper compared to P3D1. Live (green)/Dead (red) staining confirmed high cell viability on the P3D2 surface with the application of cyclic tensile strain (Fig.1D). Dynamic loading enhanced all osteogenic gene expression compared to static culture conditions (Fig.1E). BMP2 expression was considerably higher than the static baseline, with a significant increase between DLx1 and DLx2, while ALP, Runx2 and OPN showed amplified expression on DLx1 and leveled off after DL×2. Compared to the static control, OCN expression was higher with each loading event (Fig.1E).CONCLUSION:The hMSCs seeded on the rough Ti surfaces and exposed to dynamic loading experienced amplification in the osteogenic expression (above that seen with surface-feature driven differentiation), indicating synergistic effects of the material microenvironment on differentiation and the macro environment through strain distribution enabled by the truss design.

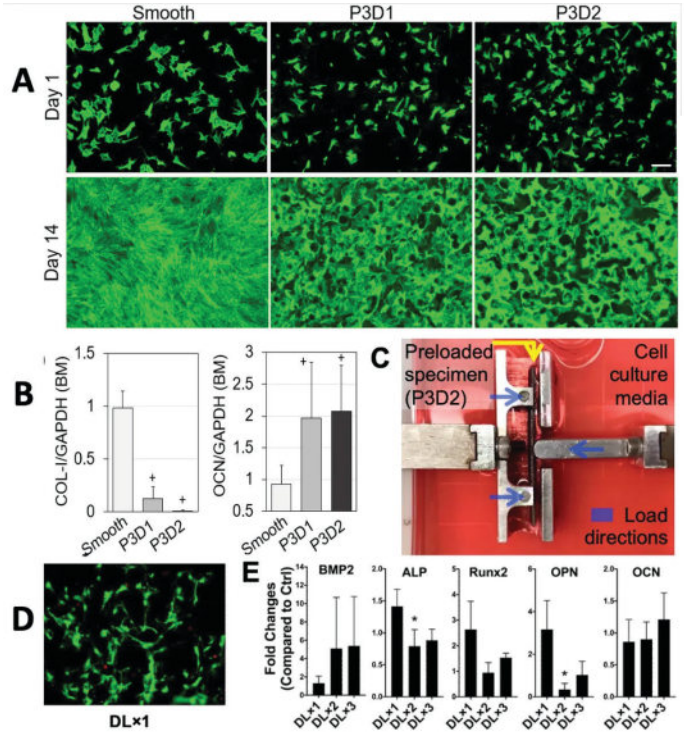

Figure 1: (A) Cell morphology at days 1 and 14. (B) Gene expression in basal media comparing smooth vs. rough titanium surfaces, (C) Image of bioreactor, (D) Live (green)/Dead (red) stain images (5X, after DL×1), (E) Gene expression: BMP2, ALP, Runx2, Osteopontin (OPN), or Osteocalcin (OCN) (n=3, *: p<0.05 vs. DL×1).

LB SAT-612

Effect of implant surface roughness and porosity on osteoblastic genes expression in Bone marrow Mesenchymal stem cells *Ali Kiapour[1], Xin Xiaonan[2], Elie Massaad[3], John Shin[3], David Rowe[4]. [1]Massachusetts General Hospital, Harvard Medical School, [2]Department of Reconstructive Sciences, University of Connecticut, United States, [3]Department of Neurosurgery, Massachusetts General Hospital, Harvard Medical School, United States, [4]University of Connecticut Health Center, United States

INTRODUCTION: Hierarchal surface roughness of the 3D printed orthopedic implants can lead to better osteointegration rates compared to conventional PEEK or machined (smooth surface) titanium implants. We compared P3D (Rough Ti),SmTi (Smooth Ti),and PEEK surfaces for bone differentiation through assessing osteogenesis rate and magnitude, including a bone formation regulator and early/late bone differentiation markers.METHODS: BSP-GFP/DMP-RFP transgenic mouse bone marrow stem cells were used to monitor bone mineralization with fluorescently-tagged genes. The BSP and DMP proteins, located in bone tissue and involved in mineralization, were evaluated for gene activation in newly formed osteoblasts and mineral-embedded osteocytes (figure-1a). Low-density, first-passaged cells from the primary bone marrow stromal culture (BMSCs) were seeded at 10e6 cells/mL onto three replicate plates: P3D, SmTi or PEEK. From days 7 through 22, cell constructs were placed under osteogenic conditions. The plates were harvested on days 3,7,14, and 22 and evaluated for fluorescence and RNA expression. Cell entry into osteogenesis was determined by fluorescence intensity at day 22.RESULTS: Significantly greater percentage of BMSC-derived progenitor cells were osteogenic on the P3D Ti surface at day 22 (Figure-1b, p<0.05) as compared to SmTi and PEEK. On each surface, almost all osteogenic markers increased over time with maximum osteogenic gene expression occurring at day 14 (Figure-1c). BMSC-derived progenitor cells cultured on P3D resulted in noticeably (P<0.005) greater increases in the late osteogenic markers Bglap and Phex (indicative of osteocyte formation) by more than 1,000- and 100-fold, respectively, at day 14. At day 22, stem cells cultured on P3D showed significant increases (P<0.005) in early osteogenic markers Alp and Col1A1, by over 15- and 35-fold respectively.DISCUSSION: 3D-printed rough Ti surface enabled a greater proportion of stem cells to enter the osteogenic lineage relative to PEEK and SmTi surfaces. Stem cells on the P3D surface resulted in greater gene expression master regulators of bone differentiation, early bone markers, and markers associated with bony mineralization. Faster and more robust late-stage osteogenic differentiation was demonstrated (>100-fold) increase in osteocalcin and Phex for P3D relative to PEEK and SmTi. These attributes may facilitate a more rapid and stable fixation of the bone-implant interface post surgical intervention.

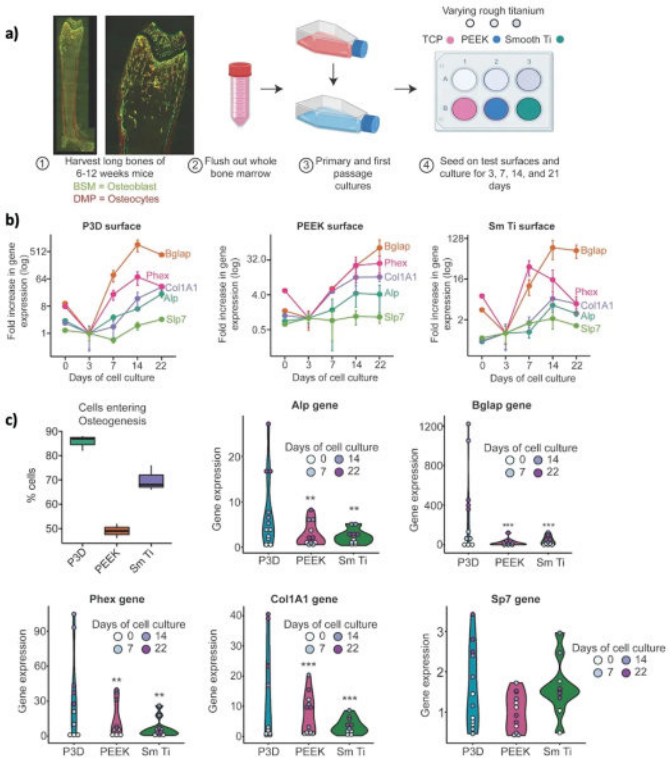

Figure 1. a) Experimental setup b)Osteogenic gene expression over time (day 3, 7, 14 and 22) for the BMSCs cultured on (left) P3D, (middle) PEEK and (right) smooth titanium.
c) Comparison P3D for markers of osteogenic expression versus PEEK and SmTi at each time point of the growth curve.

Severe Prolonged Hypocalcemia due to Sensipar in a Patient after Monoglandular Parathyroidectomy *Tanya Aggarwal[1], Evgenia Korytnaya[2], Young Min Cho[3]. [1]Northeast Georgia Medical Center, United States, [2]Peach State Endocrinology, United States, [3]Donald & Barbara Zucker School of Medicine, United States

BackgroundCinacalcet is a calcimimetic that is used for treatment of hypercalcemia in patients with primary hyperparathyroidism (PHPT) who are unable to undergo parathyroidectomy. It is sometimes used as a bridge to parathyroidectomy when patients with PHPT present with severe hypercalcemia and surgical treatment is delayed.Case presentationA 78-year-old Caucasian man with hypertension, stage IIIa chronic kidney disease presented from the nursing home (NH) with weakness, and confusion and was found to have a calcium (Ca) level of 15.7 mg/dl, serum creatinine (sCr) of 2.3 mg/dL, PTH of 295.2 pg/ml, phosphorus 1.8 mg/dl. He was treated with intravenous (IV) fluids, subcutaneous calcitonin, and pamidronate IV. Ca and sCr improved to 11.8 mg/dl and 0.95 mg/dl respectively. After discharge, Ca levels increased to 13 mg/dl and he was started on Cinacalcet. ?Computerized tomography of the parathyroid glands showed a solitary right lower pole parathyroid adenoma and parathyroid surgery was planned. Doses of Cinacalcet were gradually titrated over 11 months preceding surgery up to 90 mg three times a day with Ca in the 10-11's

mg/dl range. Monoglandular parathyroidectomy was performed. The patient was readmitted 11 days post-op with Ca 4.7 mg/dl, magnesium 1.2 mg/dl, phosphorus 5.6 mg/dl, vitamin D25OH 113 ng/ml, PTH 16.8 pg/ml, sCr 1.37 mg/dL. A review of the medication list from his NH confirmed the administration of cinacalcet. The patient was started on IV calcium infusion, oral calcium carbonate and calcitriol requiring over 13 grams of elemental calcium per day for two days before his Ca finally improved to 7.7 mg/dl. ?Hypomagnesemia was corrected. Since the patient was on pantoprazole he was switched to calcium citrate (2520 mg of elemental calcium per day) in addition to calcitriol 1 mcg twice a day. Three weeks later hypocalcemia resolved, and he was taken off all supplements.Conclusion:There are currently no guidelines addressing the use of calcimimetics in the preoperative period in patients with PHPT. We describe a case of severe prolonged hypocalcemia due to Cinacalcet in a patient with PHPT who underwent monoglandular parathyroidectomy. There is a need for consensus recommendations addressing the optimal timing for discontinuation of calcimimetics prior to parathyroidectomy. Effective communication between providers involved in the care of such patients is needed to avoid complications

Novel Human Osteoblast Effector Gene EPDR1 Demonstrates Differing Outcomes after Knock-down or Knock-out in Murine In vitro Osteoblastogenesis and During Murine Bone Modeling *Yadav Wagley[1], Parker K. Acevedo[1], Karen Kessell[1], Robert W Goulet[1], Conor S. Locke[1], Tristan Maerz[1], Kenneth M. Kozloff[1], James A Pippin[2], Alessandra Chesi[2], Andrew D. Wells[2], Struan Grant[3], Kurt Hankenson[1]. [1]University of Michigan, United States; [2]Center for Spatial and Functional Genomics, United States; [3]Children s Hospital of Philadelphia / University of Pennsylvania, United States

EPDR1 is a recently characterized human osteoblast effector gene previously identified by intersecting BMD GWAS data with functional genomics in differentiating human mesenchymal stem cells (MSC). Loss of EPDR1 function biases hMSC towards adipogenic differentiation via metabolic and immunologic reprogramming. However, the role of EPDR1 in murine cells and bone development is not known. We generated Epdr1fl/fl mice to investigate its role in osteoblastic and adipogenic differentiation of mouse MSC (mMSC) and to dissect the effect of global loss of EPDR1 function during bone development using whole body knock-out EIIA-Cre mediated genetic recombination. Adenovirus mediated recombination of Epdr1fl/fl mMSC led to a decrease in alkaline phosphatase expression and mineralization similar to our published results with hMSC. The Epdr1 recombined cells showed a general reduction in Runx2, Alpl, Sp7, Ibsp, and Bglap expression suggesting a requirement of EPDR1 function for osteoblastogenesis. However, unlike results observed in hMSC upon EPDR1 silencing, mMSC adipogenesis decreased with Epdr1 recombination and was accompanied by a modest reduction in Pparg gene expression. Next, we crossed the Epdr1fl/fl mice with EIIA-Cre to generate global Epdr1 knock-out mice. These mice appeared normal at birth and showed no developmental abnormalities. Intriguingly, the overall body weight of Epdr1 knockout male mice showed a reduction at 6 months of age that could be associated with reduction in the amount of body fat depots. At the cellular level, mMSC harvested from 1-month old Epdr1-/- showed a minor reduction in mineralization capability, but these differences were not observed with cells harvested from 3- and 6-months old mice. Correspondingly, bone parameters of the 6 months old Epdr1fl/fl and Epdr1-/- mice using microCT imaging of the femurs showed no major genotype differences. Gene expression analysis using the tibial diaphysis and metaphysis from the same mice groups did not establish genotype or sex-specific reduction on bone metabolism. We are currently processing microCT images from the 1-and 3-month-old femur samples, but do not anticipate significant changes. Collectively, these results indicate a compensatory mechanism could exist upon global Epdr1 knock-out in the murine model, and warrants future investigations using conditional loss of Epdr1 function to understand osteoblast and adipocyte cell lineage specific roles in vivo.

Rapamycin Prevents Senescence and Functional Decline of High-Density Placental Mesenchymal Stem Cells *Kristin Delgado[1], Aaron Sheppard[1]. [1]LSU Health Science Shreveport School of Medicine, United States

Our group has shown that high-density mesenchymal stromal cell (MSC) sheet implantation improves bone healing in a critical-sized bone defect model; however, these cells exhibit increased aging and cellular senescence in prolonged sheet culture, diminishing their therapeutic potential. Promisingly, rapamycin has emerged as a potential agent to rejuvenate aged MSCs. This study aimed to confirm rapamycin's ability to prevent senescence and isolate specific pathways/genes responsible. Human pMSCs were seeded at high density (65,000 cell/cm²) and treated with either rapamycin (10 nM) or control vehicle (DMSO) for up to 7 days. Senescence and autophagy were assessed by senescence-associated ?-galactosidase (SA ?-Gal) staining and DAPI nuclear staining, respectively. Additionally, cell culture media was extracted at different time points to assess senescence-associated cytokines IL-6 and IL-8 via ELISA. Finally, total RNA was extracted for differential gene analysis via GeneChip Clariom A Human Arrays. Rapamycin significantly decreased SA ?-Gal staining at all time points, with 67.7% and 72.9% less area when compared to control at day 4 and 7, respectively. Senescent-associated cytokine IL-6 levels were significantly reduced when compared to control, with 614.3 pg/ml and 286.6 pg/ml decreased at day 2 an 4 of treatment, respectively. Interestingly, IL-8 expression had increased significantly at all time points, with a 979.9 pg/ml difference at day 4 of treatment compared to vehicle. Autophagy-associated vacuoles-stained area had a 3.94-fold increase at day 4 of treatment compared to vehicle. Microarray gene analysis identified a total of 429 genes with a 2-fold or greater change in expression following treatment. FoxO, cellular senescence, and cell cycle pathways are some of many effected with significantly altered expression of FBXO32, PSAT1, CXCL8, and MYC, acting as potential players in rapamycin's anti-aging effects. Rapamycin has proven effective in prolonging pMSC lifespan. Numerous pathways identified in this study may explain rapamycin's anti-aging functionality and lead to the creation of therapeutics specifically targeting relevant genes. The presence of enhanced IL-8 may prove beneficial in stem cell wound healing application. These findings prove rapamycin is a candidate for improving stem cell preparation and support previous studies indicating IL-8 may enhance stem cell viability, results useful in advancing stem cell therapy for bone remodeling.

Investigating The Cell Population That Produces BMP2 In The Periosteum. *David Maridas[1], Laura Gamer[1], Emily Moore[1], Vicki Rosen[1]. [1]Harvard School of Dental Medicine, United States

Our lab previously reported that deletion of BMP2 in Prx1-expressing skeletal progenitors (Bmp2;Prx1 cKO mice) results in longitudinal and appositional growth deficiency of bones in the appendicular skeleton. Additionally, Bmp2;Prx1 cKO mice have fragile long bones that spontaneously fracture and do not heal, reinforcing the central role that BMP2 signaling plays in periosteal function. However, Prx1-Cre targets a wide range of skeletal progenitors, making it unclear if a specific cell population is responsible for producing BMP2. To begin to investigate this question, we used the recently described Ctsk-Cre strain to delete BMP2 in a specific osteogenic subpopulation of cells in the periosteum (Bmp2;Ctsk cKO mice). In contrast to Bmp2;Prx1cKO mice, Bmp2;Ctsk cKO mice did not exhibit alterations in longitudinal or appositional growth at 4 and 12 weeks of age. Concordantly, no spontaneous fractures were detected at 12 weeks of age in Bmp2;Ctsk cKO mice. We then performed femur fractures at 12 weeks of age in Bmp2;Prx1 cKO and Bmp2;Ctsk cKO mice. At 5 days post-fracture, periosteum expansion, callus formation, and chondrogenesis occur similarly in controls and Bmp2;Ctsk cKO mice but are absent in Bmp2;Prx1 cKO mice. Together, our data indicate that Ctsk-Cre driven deletion of BMP2 does not recapitulate the Prx1-Cre phenotype and therefore Ctsk-expressing cells are not a critical source of BMP2 in the periosteum. We were also curious about whether Prx1-Cre deletion of BMP2 results in the loss of the cell population that normally produces BMP2 in the periosteum. To investigate this possibility, we crossed mice carrying the Bmp2-LacZ knock-in (loss of function allele) with the Bmp2;Prx1 cKO mice. In this mouse model (Bmp2;Prx1/LacZ cKO), BMP2 is deleted from the long bones because the LacZ knock-in gene is nonfunctional. However, cells that would otherwise produce BMP2 will be LacZ positive. We found that Bmp2;Prx1/LacZ cKO mice recapitulated the longitudinal and appositional growth phenotype of the Bmp2;Prx1 cKO mice. When fractured, the periosteum of the Bmp2;Prx1/LacZ cKO mice did not expand and callus formation did not occur, yet we detected LacZ staining in cells located at the fracture site, indicating that the cell population responsible for producing Bmp2 during fracture is still present in the adult periosteum even with deletion of Bmp2 with Prx1-Cre. In summary, our data suggest that a subpopulation of periosteal cells that are

Prx1-positive but Ctsk-negative produce BMP2 in the periosteum. Additionally, these cells survive but are dysfunctional in the absence of BMP2.

Integrated microRNA-mRNA analyses of the osteogenic induction of a helioxanthin derivative in human dental pulp stem cells *Yasuyuki Fujii[1,] Sakura Minami[2,] Ayano Hatori[2,] Yoko Kawase-Koga[3,] Toru Ogasawara[4,] Hayato Hamada[2,] Yuki Kanno[2,] Daichi Chikazu[2,] [1]Tokyo medical university, Japan, [2]Tokyo Medical University, Japan, [3]Tokyo Women's Medical University, Japan, [4]The University of Tokyo, Japan

Dental pulp stem cells (DPSCs) have high proliferative and multilineage differentiation potential in mesenchymal stem cells. Many studies have reported that DPSCs have osteogenic differentiation ability and that small chemical compounds induce osteogenesis of DPSCs. We previously reported that the helioxanthin derivative 4-(4-methoxyphenyl) pyrido[40,30:4,5]thieno[2,3-b]pyridine-2-carboxamide (TH), an osteogenic small molecule, induced the osteogenic differentiation of DPSCs. However, this osteogenesis mechanism of TH in DPSCs are still unknown. The purpose of this study was to identify functional exosomal microRNAs (miRNAs) and the key genes involved in the TH-induced osteogenesis of DPSCs.DPSCs were obtained from dental pulp of the wisdom teeth of three healthy patients and cultured with or without TH (approval No. T2020-0343 by the Institutional Ethics Committee of the Faculty of Medicine, Tokyo Medical University, Japan; approved on January 5, 2021). miRNAs were extracted from DPSCs-derived exosomes. These gene expression patterns were compared using RNA-Seq and miRNA-Seq. To investigate the specific miRNA/mRNA interacting network, these data were analyzed and the functional analyses were generated through the use of Ingenuity Pathway Analysis (IPA, QIAGEN Inc.).Alkaline phosphatase (ALP) staining showed that TH enhanced ALP activity in DPSCs at 7 days. RT-PCR analyses showed that TH-induced DPSCs had significantly higher expression levels of ALP and type 1 collagen alpha 1 in day 7. RNA-Seq and miRNA-Seq showed 869 differentially expressed genes (DEGs) and 18 miRNA-DEGs. Integrated miRNA-mRNA analyses showed these miRNAs have the targeting information of 277 mRNAs in DEGs. Among them, 24 target genes known to be involved in the differentiation of bone cells and 17 target genes known to be involved in the differentiation of osteoblasts were identified. The upstream regulator analysis predicted WNT3a may be responsible for gene expression changes in DPSCs after TH stimulation.The exosomal miRNA regulatory networks might play vital roles in TH-induced osteogenic differentiation of DPSCs. These results provide support for further investigations into the mechanism of osteogenesis in DPSCs.

Deletion of Ror2 in skeletal muscle promotes intramuscular adipogenesis during aging *Martina Pauk[1,] Hiroaki Saito[1,] Eric Hesse[1,] Hanna Taipaleenmäki[1,] [1]1 Institute of Musculoskeletal Medicine, University Hospital, LMU Munich, Munich, Germany; 2 Musculoskeletal University Center Munich, University Hospital, LMU Munich, Munich, Germany, Germany

Decline in skeletal muscle function during aging involves the accumulation of fatty and fibrotic tissue within muscles. Recently, a specific group of stromal cells called fibro-adipogenic progenitors (FAPs) has been identified as the cellular source of fat and fibrous deposits in muscles. However, the mechanisms behind the differentiation of FAPs into adipocytes or fibroblasts are not well understood. To investigate this question, we isolated FAPs from mouse muscles and induced their differentiation into adipogenic and fibroblast lineages. During this process, an increased presence of the non-canonical Wnt receptor Ror-family receptor tyrosine kinases 2 (Ror2) was observed, suggesting a potential role for Ror2 in the differentiation of adipocytes and fibroblasts. Indeed, inhibition of Ror2 using siRNA, enhanced adipocyte differentiation of FAPs, as indicated by increased Oil Red O staining and the expression of adipogenic markers such as Ppar?, Adiponectin, Perilipin, and Fabp4. On the other hand, absence of Ror2 reduced the differentiation of FAPs into fibroblasts, as demonstrated by decreased collagen production and deposition. To further investigate the impact of Ror2 on the age-related decline of muscle function in vivo, we generated mice with a specific deletion of Ror2 in their skeletal muscles using the Cre-recombinase under the control of the 1.5 kb fragment of the mouse myogenin promoter and the 1 kb mouse Mef2c enhancer element (Myo-Cre+). Muscle-specific deletion of Ror2 in aged female mice (40-55 weeks old) did not affect body weight, muscle weight, or myofiber size. However, it significantly decreased the function of the soleus muscle in Myo-Cre+;Ror2fl/fl mice compared to control, as evidenced by reduced ex vivo muscle contractility and endurance. Histological analysis revealed the infiltration of inflammatory mononuclear cells and necrotic fibers in the muscles of Myo-Cre+;Ror2fl/fl mice, along with increased fatty deposits detected by Oil Red O staining. In summary, our study uncovers the role of Ror2 in regulating FAP differentiation in vitro, while its deletion in muscle leads to increased intramuscular adipogenesis during aging, potentially contributing to reduced muscle function. These findings provide new insights into the function of FAPs and non-canonical Wnt signaling, thereby improving the understanding of age-related decline in muscle function.

VITamin D and OmegA-3 TriaL (VITAL): Genetics, Vitamin D Biomarkers, and Fractures *Meryl LeBoff[1,] Sharon Chou[1,] Dana Ratnarajah[1,] Nancy Cook[1,] Franco Giulianini[1,] Julie Buring[1,] JoAnn Manson[1,] Daniel Chasman[1,] [1]Brigham and Women's Hospital , United States

Supplemental vitamin D is commonly used in the general population to improve bone health. We recently reported that supplemental vitamin D3 (2000 IU/d) vs. placebo did not reduce total, nonvertebral, and hip fractures in 25,871 generally healthy U.S. men (aged >=50) and women (aged >=55) enrolled in the VITamin D and OmegA-3 TriaL (VITAL). The objective of this study was to evaluate modification of randomized vitamin D supplementation by genetic variation in vitamin D metabolism, absorption, and receptor function for 1) changes in vitamin D biomarkers (total 25OHD, PTH and calcium) and 2) incident fractures in a case-cohort. Genotyping using the Global Screening Array was performed by Erasmus Medical Center Rotterdam (Netherlands), with imputation to the TOPMed reference panel. Candidate single nucleotide polymorphisms (SNPs) were selected from vitamin D-related pathways (CYP27A1 [2 SNPs], GC/DBP, CD36, NPC1L1, CYP2R1, FGF23, VDR [2 SNPs], CYP27B1 [2 SNPs], SCARB1, and CYP24A1). Total 25OHD, PTH, and calcium blood levels were measured at baseline and two years of follow-up. Incident fractures in VITAL were reported on annual questionnaires and adjudicated by medical record review. The sample for this study was restricted to individuals of European ancestry (verified by genetics) and comprised of nested incident cases of fractures (N= 834) and an age/sex-matched subcohort (N= 847) selected at random from ~72% of VITAL participants who consented to genetic analysis. This case/subcohort was 68% female with mean (+/-SD) age of 70.4+/-6.8 years and BMI of 26.8+/-5.1 kg/m2. We tested for significant interaction between an additive encoding of genetic variants and randomized vitamin D vs. placebo allocation in association with 2-year changes in blood levels of total 25OHD (N=440), PTH (N=442), and calcium (N=336) and incident fractures. There were no interactions between candidate variants and randomized vitamin D vs. placebo allocation for these circulating measures of vitamin D supplementation or for incident fractures in models adjusted for age, sex, and BMI (Table 1). In VITAL, genetic differences in vitamin D-related pathways did not 1) predict biochemical response to vitamin D supplementation or 2) reveal any genetic profiles that may confer a benefit of vitamin D supplementation on fracture risk. Future VITAL studies will focus on an expanded set of pharmacogenetic hypotheses involving effects of supplemental vitamin D on bone and musculoskeletal outcomes.

Table 1. Fracture SNP Associations adjusted for age, sex, and BMI

Sex differences in the relationship between body fat, vitamin D status and biomarkers of bone and fat metabolism in adult men and women. *Marina Bonanno[1,] Gretel Pellegrini[1,] graciela brito[1,] beatriz oliveri[1,] Susana Noemi Zeni[1,] [1]INIGEM, Argentina

Evidence from diverse studies suggests that obesity is associated with low vitamin D (VD) status evaluated by the levels of 25 hydroxyVD (25HOD). Fat sequestration of VD in fat mass has been pointed out as a plausible explanation for this low levels of circulating VD. Although obesity can be assessed by body mass index (BMI), body fat content appears to provide a clearer picture of health. Our objective was to evaluate according to ranges of obesity the correlation between circulating 25HOD levels, total osteocalcin (OCN), undercarboxilated OCN (ucOCN) and the development of insulin resistance in obese adult women and men. As OCN is involved in glucose homeostasis and to avoid the close relation between obesity and impaired glucose homeostasis we only included in the study, non-diabetic subjects of both genders with normal levels of glycemia and HbA1c, presenting overweight (OW) and obesity (O). Participants aged 40 to 79 years (50 men and 143 women; 96 post and 47 premenopausal) were grouped according to sex and age (40-59 and >60 years). After body composition was recorded by bioimpedance, they were classified according to body fat percentage (%BF) (30-39 or >40). Glucose , triglycerides, HDL cholesterol and waist cir-

cumference (WC) were measured by habitual methods and insuline, leptin, 25HOD and total osteocalcin (OCN) by ELISA. BMI and Insulin resistance was also calculated. Some results (mean +/- SD) are shown as <40 or 40 to 60 years in the following order: men OW and O, women OW BMI (kg/m2): 29.1+/-0.3.a 37.5+/-7.5b 28.9+/-1.49a 37.2+/-7.31b 29.2+/-0.6a 37.3+/-4.9b 28.0+/-1.7a 34.2+/-4.5b% BF: 35.6+/-5.2a 42.5+/-5.4b 35.4+/-1.7a 49.0+/-8.2b 35.5+/-6.2a 45.8+/-4.7b 39.4+/-1.9a 49.1+/-6.9bCC (cm): 105.1+/-1.5a 120.0+/-17.2b 93.6+/-8.1a 108.8+/-15.1a 103.5+/-0.7a 120.1+/-6.7b 9.7+/-9.2a 105.7+/-9.5aGlu (mg/dL): 97.7+/-22.7 99.9+/-17.4 91.1+/-11.8 96.4+/-18.3 95.5+/-30.4a 104.9+/-12.2b 98.2+/-7.2a 97.2+/-10.8aLeptina (ng/ml): 2.4+/-1.9a 15.9+/-15.2c 11.1+/-5.7b 28.3+/-15.7d 2.72+/-3.1a 13.1+/-6.7c 9.6+/-6.0b 21.1+/-13.2dVitamina D (ng/ml): 24.9+/-6.8b 17.4+/-7.4a 20.8+/-6.8b 18.4+/-6.3a 25.0+/-8.5b 17.2+/-4.7a 25.9+/-9.8b 20.0+/-7.5aOCN (ng/mL): 31.1+/-0.5.c 18.6+/-12.6a 32.7+/-10.2c 26.1+/-12.7b 30.4+/-0.2c 30.9+/-13.8c 30.6+/-15.8c 25.6+/-15.9aDifferent letters indicate a p<0.05. 25HOD correlated with %BF but not with BMI Conclusion: The results suggest that the associations of body fat and 25(OH)D was sex-specific, with greater clarity when %BF was used instead of BMI to classify obesity.

Effects of IL-17 Blockade on Skeletal Microarchitecture in Patients with Axial Spondyloarthritis: An HR-pQCT Study *Insa Mannstadt[1], Donald McMahon[2], Douglas N Mintz[1], Weija Yuan[1], Linda Russell[1], Emma Billings[3], Susan M Goodman[1], Dalit Ashany[1], Emily Stein[1]. [1]Hospital for Special Surgery, United States. [2]Columbia University College of Physicians and Surgeons, . [3]Hospital for Special Surgery ,

Axial spondyloarthritis (AxSpA), a chronic inflammatory rheumatic disease, causes abnormal bone growth at the spine and paradoxically has been linked to osteoporosis and fragility fractures. While tumor necrosis factor alpha inhibitors have been shown to improve skeletal health in patients with AxSpA, the effect of newer medications that block interleukin-17 (IL-17) on bone metabolism remains unclear. This prospective study investigated the impact of IL-17 blockade on bone density (BMD) and microarchitecture in AxSpA. We hypothesized that treatment initiation would be associated with improved BMD and microarchitecture. Skeletal assessments included areal BMD (aBMD) and trabecular bone score (TBS) by DXA, volumetric BMD (vBMD) and microarchitecture by high-resolution peripheral QCT (HRpQCT2) at baseline and 12-months. DXA and HRpQCT measurements from patients were compared to those of age and sex-matched individuals in reference cohorts. Changes in imaging parameters were compared using Wilcoxon and paired t-tests, and predictors of change in HRpQCT were analyzed using multivariate linear regression. Of the 22 AxSpA participants, 55% were female (33% postmenopausal), mean age was 40 years, and mean BMI 30 kg/m2. Half (55%) were HLAB27 positive, mean symptom duration was 10 years, and C-reactive protein (CRP) was elevated in 32% of participants. At baseline, mean DXA and HRpQCT Z-scores were within one standard deviation of the healthy reference population. At 12-months, >80% of participants reported 100% medication adherence. Standardized assessments of disease activity improved, with a decrease in Bath Ankylosing Spondylitis Disease Activity (BASDAI -33%, p<0.01) and Metrology Index (BASMI -22%, p=0.01; Table) There was no significant change in aBMD or TBS. By HRpQCT at the radius, declines were observed in total vBMD (-2%, p=0.04) and trabecular vBMD (-2%, p=0.04). Radial trabecular separation tended to increase (4%, p=0.06). Elevated CRP tended to be associated with the decline in total vBMD (R=0.55, p=0.09). In summary, participants with AxSpA who began IL-17 blockade experienced significant improvements in clinical symptoms but had no change or small declines in BMD and microarchitecture. As our study was not controlled, we lack data regarding whether treatment may have attenuated larger declines associated with disease progression. Larger, controlled studies are needed to further investigate the long-term skeletal effects of IL-17 blockade.

Table: 12-Month Changes in Disease Characteristics and Skeletal Indices After Initiation of IL-17 Blockade

	Baseline	12-months	% change	p-value

Protein phosphatase PPM1A maintains bone homeostasis via regulating TGF-?/Smad2 signaling in osteoblast *Qinwen Ge[1], Kai-ao Zou[1], Ping-er Wang[1], Luwei Xiao[1], Di Chen[2], Xia Lin[3], Peijian Tong[1], Hongting Jin[1]. [1]Institute of Orthopaedics and Traumatology, The First Affiliated Hospital of Zhejiang Chinese Medical University, China. [2]Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, China. [3]Zhejiang University, China

Protein phosphatase magnesium-dependent 1A (PPM1A) is a member of the metal-dependent phosphatases family while its role in maintaining bone homeostasis and the precise mechanism by which PPM1A regulates osteogenesis is still largely not elucidated. To explore the role of PPM1A in bone homeostasis in vivo, we generated global Ppm1a knockout (KO) mice. The ?-CT analysis showed that PPM1A deficiency dramatically decreased trabecular bone mass at distal femur metaphysis and lumbar vertebra, but did not alter cortical bone morphology. Compared to wild-type mice, KO mice had lower osteocalcin and ALP expression and unchanged expression of osteoclastic marker cathepsin K. Also, double calcein labelling assay and von Kossa staining revealed Ppm1a ablation reduced trabecular bone mineral apposition. Moreover, KO mice displayed a diminished bone regeneration ability after femoral bone marrow ablation. In vitro, we found an increased Ppm1a mRNA expression during osteogenesis. Conversely, primary osteoblast isolated from KO mice exhibited an impaired osteogenesis as supported by the decreased mRNA expressions of osteogenic genes and reduced ALP staining and ARS staining intensity. Mechanistically, we noted that Ppm1a deficiency reduced the dephosphorylation of Smad2, causing excessive TGF-? signaling, and co-immunoprecipitation assay confirmed the interaction between PPM1A and p-Smad2 in osteoblast. Importantly, Ppm1a?/? osteoblast treated with SD-208, a selective inhibitor for TGF-?/Smad2 signaling activation, showed a restored bone formation phenotype as determined by the increased mRNA expression of osteogenic gene and ALP staining. Similarly, SD-208 treatment in vivo largely rescued the osteogenesis defects and impaired bone regeneration in KO mice, suggesting PPM1A promoted bone formation and bone regeneration mainly by regulating TGF-?/Smad2 signaling. Additionally, we identified that Miltefosine (MF), an FDA approved anti-leishmanial drug, which has been recently reported as a PPM1A activator for Alzheimer's disease, could facilitates osteogenesis in vitro and enhance bone regeneration in vivo while Ppm1a deletion completely blocked this bone anabolic action. Simultaneously, we demonstrated that MF administration strikingly alleviated bone loss in ovariectomy-induced mice. Taken together, this study revealed that PPM1A promoted osteoblastic bone formation via regulating TGF-?/Smad2 signaling and highlighted the potential of MF for osteoporosis treatment.

Regulation of differential expression and spatial distribution of the endosomal proteins in osteoblasts *Waddell Holmes[1], Marcus Winogradzki[1], Shreya Patel[1], Ahmad Othman[2], Niyati Patel[1], Ryan Ross[1], Jitesh Pratap[1]. [1]Rush University Medical Center, United States. [2]Northwestern University, United States

Recent transcriptomics and proteomics studies with differentiating osteoblasts (OB) revealed endosomal proteins as the most prominent upregulated cluster. The endosomal pathway regulates the fate of the internalized molecules to the plasma membrane, trans-Golgi network, or the lysosome. Endosomes also serve as a platform to control the growth factor signaling output. However, the regulation of expression and subcellular distribution of endosomes during osteoblast differentiation are currently unknown. Here, we utilized multiple OB models to examine the levels and subcellular distribution of the endosomal pathway-related genes via qRT-PCR, western blotting, and confocal microscopy. We found upregulation of mRNA and protein levels of Syntaxin 6 (STX6) and Rab5 in differentiating mouse IDG-SW3 osteoblasts. We found significant upregulation of mRNA levels of early endosomal antigen-1 (EEA1) and Rab7 while protein levels remain unchanged.?Next, to understand the regulation of expression levels and subcellular distribution, we examined the role of Runx2, a master regulator of osteoblast differentiation. We utilized WT and Runx2 knockout (KO) calvarial osteoblasts and found a significant reduction in EEA1 and increased levels of Caveolin-1 and Rab11 in Runx2 KO cells. The distribution and trafficking of endosomes depends on the stability of microtubules (MTs), therefore, we treated OB with MT-targeting agents and found that stabilizing MTs via docetaxel treatment increases the endosomal protein levels. Interestingly, MT depolymerization via vinblastine or nocodazole resulted in the aggregation of EEA1 puncta in Runx2 KO cells without changing the protein levels. Stabilization of MTs via tubacin treatment also yielded endosomal aggregation. These results indicate that changes in the MT dynamics and Runx2 levels can differentially regulate endosomal distribution. Data analysis of Runx2 ChIP-seq studies revealed Runx2 recruitment on STX6 promoter, suggesting a novel Runx2 target gene. Finally, to determine the effect of nutritional stress on endosomal proteins, we examined the serum- and glucose- starved OB and found reduced levels of Rab5 and Rab7.? Taken together, our studies identified the key changes in the endosomal landscape during osteoblast differentiation. Our findings suggest a novel regulation of OB differentiation via endosomal pathway proteins.

Foci-Xpress: Automated and fast nuclear foci counting tool *Woo-Jin Kim[1], Ki-Tae Kim[1], Hyun-Jung Kim[1], Hye-Rim Shin[1], Heein Yoon[1], Seung Gwa Park[1], Min-Sang Park[1], Hyun-Mo Ryoo[1], Jae-I Moon[1]. [1]Seoul National University, Republic of Korea

Quantification of DNA damage-induced foci can be used to determine DNA damage caused by oxidative stress, radiation, or aging. ?H2AX, a form of phosphorylated histone H2AX induced by DNA double-strand breaks, is one of the most sensitive markers of DNA damage. Counting foci is tedious and time-consuming for researchers. We developed open-source software that automatically counts the number of foci from the indicated image files. We compared the ?H2AX foci counting efficiency, velocity, accuracy, and convenience of the Foci Xpress with those of other conventional methods in an oxidative DNA-induced model. We can adjust the brightness of ?H2AX foci to designate a threshold of foci and assign damaged cells that have 10 or more foci over the threshold in the nucleus. The Foci-Xpress method was much faster than other conventional methods. The accuracy was similar to that of conventional methods. The biggest strength of Foci-Xpress was automation, which freed researchers from analysing equipment while counting. The greater the number of images to be counted, the greater the number of advantages. In addition, automation completely ruled out biases caused by researchers, such as individual or daily variations. Thus, Foci-Xpress is a convincing, convenient, and easily accessible focus-counting tool for cell biologists.

[4]The University of Tokyo, Graduate School of Medicine and Faculty of Medicine, Japan

Osteogenic cells play a central role in osteoclast regulation by producing RANKL and OPG. However, the precise molecular mechanisms underlying RANKL/OPG expression have not been fully understood. We explored the epigenomic landscape of osteogenic cells and identified a hitherto undescribed enhancer region in the TNFSF11 gene locus. Transcription factors involved in cell death and senescence act on this enhancer region, and genetic deletion of the enhancer leads to a high bone mass phenotype with decreased osteoclastogenesis. To characterize the OPG-producing osteogenic cells, we analyzed sc-RNAseq data and identified an extracellular matrix factor (EMF) as a marker for OPG-expressing cells. EMF-Cre mediated deletion of OPG resulted in severe osteopenia whereas RANKL-floxed EMF-Cre mice exhibit normal bone volume. Thus, OPG and RANKL are produced by distinct osteogenic subtypes, highlighting the functional diversity of osteogenic cells and the molecular mechanism of osteoclast regulation

Senescence osteoclast precursors induce SASP through cGAS-STING *Hirokazu Hattori[1], Kazuki Takaoka[1], Tomoki Kakimoto[2], Sachiko Nosaka[1], Ayaka Hatanaka[1], Masayuki Oshitani[1], Miho Ueta[1], Kazuma Noguchi[1], Hiromitsu Kishimoto[1]. [1]Department of Oral and Maxillofacial Surgery, School of Medicine, Hyogo Medical University, Japan. [2]Department of Oral and Maxillofacial Surgery, School of Medicine, Hyogo Medical University , Japan

Senescence is an unexplained life phenomenon. In recent years, it has become clear that senescent cells do not simply stop cell growth but secrete various proteins such as inflammatory cytokines and chemokines. This secretory phenomenon is called senescence-associated secretory phenotype (SASP). Cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) pathway, known as an innate immune pathway against DNA during viral infection, has been shown to induce SASP. We hypothesized that SASP factors released by osteoclast precursors (OCPs) undergoing cellular senescence with aging may affect the bone microenvironment. The purpose of this study is to elucidate the differentiation of senescent OCPs and the effects on SASP.RAW264.7 cells were used as OCPs and were cultured to passage (P)5, P10 and P20. To assess replicative senescence, the protein expressions of p53 and p-H2A.X, SA-?-gal, and telomere length were evaluated. To evaluate the ability to differentiate into osteoclasts, the expressions of TRAP and RANK and NFATc1 were evaluated. The concentration of SASP factors (IL-6, TNF-?, NO) in the culture supernatant were measured by ELISA. We extracted exosomes from the culture supernatant. The number of exosome particles was measured by ELISA and the expression of SASP factors (TGF-?1, HIF-1?, iNOS) in exosomes by western blotting, and the expression of miRNAs in exosomes were evaluated. To evaluate SASP induction pathway, the expressions of cGAS-STING pathway were assessed by western blot and ELSIA.P20 showed replicative senescence, and significantly decreased ability to differentiate into osteoclasts compared to P5 and P10. The protein expression levels of RANK and NFATc1 in cells treated with RANKL at P20 were decreased compared with those at P5 and P10. The concentration of SASP factors in the culture supernatant at P20 were significantly increased compared with those at P5 and P10. The number of exosomes at P20 was increased compared with that at P5 and P10. The protein expression level of iNOS in exosomes at P20 was increased compared with that at P5 and P10. The expression of cGAS-STING pathway was significantly elevated at P20.In conclusion, cellular senescence reduces RANKL-induced osteoclastic differentiation of RAW264.7 cells by inhibiting RANK expression. Senescent RAW264.7 cells increase production of SASP factors via cGAS-STING pathway and then release iNOS in exosomes..

The anti-osteoclastic effects of the novel geranylgeranyl diphosphate synthase inhibitor RAM2061 *Molly Muehlebach[1], Sarah Holstein[1], Yashpal Chonker[1], DJ Murry[1]. [1]University of Nebraska Medical Center, United States

Myeloma bone disease affects nearly 90% of myeloma patients, significantly impacting patient morbidity and quality of life. Current treatments include bisphosphonate therapy or monoclonal antibody denosumab, but while both treatments have been found to prevent further skeletal related events, they can be associated with adverse events such as kidney damage and osteonecrosis of the jaw. Our lab has developed a novel bisphosphonate, RAM2061, which inhibits the enzyme geranylgeranyl diphosphate synthase (GGDPS) and has been shown to have anti-myeloma effects in vitro and in vivo. In myeloma cells, we have found RAM2061 depletes intracellular levels of isoprenoid donor geranylgeranyl pyrophosphate (GGPP) necessary for the post-translational modification (geranylgeranylation) of Rab proteins. By inhibiting Rab geranylgeranylation in these cells, Rab-mediated intracellular trafficking is disrupted, inducing ER stress and subsequent apoptosis. Understanding that osteoclasts rely heavily on secretory pathways for bone resorption, we were interested in investigating whether RAM2061 could impair osteoclast activity in the same manner. We hypothesized that RAM2061 will disrupt Rab and Rho protein geranylgeranylation, disrupting intracellular trafficking and cytoskeletal rearrangement necessary for osteoclast function. In RAW264.7 pre-osteoclast cells we demonstrated that RAM2061 induces ER stress and the unfolded protein response pathway (UPR)-mediated apoptosis in a concentration-dependent manner. In mature osteoclasts, we found RAM2061 disrupts osteoclast differentiation by significantly downregulating expression of osteoclast-specific genes and inhibiting tartrate resistant acid phosphatase-positive osteoclast formation. Furthermore, we found RAM2061 inhibits osteoclast resorption at concentrations as low as 200 nM. Upon further investigation, we determined RAM2061 to disrupt Rho protein geranylgeranylation, inhibiting Rho signaling and cytoskeletal rearrangement essential for osteoclast differentiation and function. Therefore, these studies reveal that RAM2061 may represent a novel therapy for treatment of myeloma bone disease and potentially other osteoresorptive diseases.

Atenolol reduces human osteoclast resorption, but not differentiation in vitro *Tyler Roy[1], Rebecca Peters[4], David Monroe[3], Aaron Brown[4], Sundeep Khosla[5], Christine Lary[6], Katherine Motyl[7]. [1], [4]MaineHealth Institute for Research, [3]Mayo Foundation, United States. [4]MaineHealth Institute for Research, United States. [5]Mayo Clinic College of Medicine, United States. [6]Northeastern University, [7]MaineHealth, United States

?-adrenergic receptor antagonists (a.k.a. ?-blockers) are associated with increased bone mineral density and reduced fracture risk. In addition to osteoblast-mediated suppression of RANKL, we have shown that ?-blockers also directly suppress primary mouse osteoclastogenesis. While mouse models are convenient for studying osteoclast (OCL) function, primary human OCLs are needed to increase clinical relevance of our findings. Here, we report our protocol for culturing functional OCLs from human peripheral blood mononuclear cells (HPBMCs) isolated from patient-derived blood samples. Specifically, we are using this protocol in an ongoing ancillary study to the Atenolol for the Prevention of Osteoporosis (APO) clinical trial (NCT04905277) to test the effectiveness of atenolol, a ?-blocker on primary osteoclasts derived from women aged 50 to 75. To limit estrogen receptor activity and promote osteoclast differentiation, HPBMCs are cultured in an osteoclastogenic media composed of phenol red-free ?-MEM, charcoal-stripped FBS, M-CSF, and RANKL. OCLs are cultured on plastic and bone slices for 14 days with either vehicle (H2O) or atenolol (15 ?M) throughout osteoclast differentiation. To assess osteoclast number and size, mature osteoclasts cultured on plastic and bone slices are fixed on day 14 and stained for tartrate-resistant acid phosphatase (TRAP). Osteoclasts are imaged and analyzed for number and total TRAP positive area using a semi-automated method we developed using ImageJ. Additionally, media is collected from bone slices on day 14 to quantify levels of carboxy-terminal collagen crosslinks (CTX-1) as a measure of bone resorption. While preliminary data shows atenolol does not affect the number of OCLs or total area covered on bone slices (n=18 participants, with at least 5 replicates each), CTX-1 levels are significantly reduced (59%, p=0.0063, n=8) with 15 µM atenolol treatment throughout all of differentiation. In summary, atenolol treated osteoclasts are less efficient at resorbing bone, which complements the known effect of atenolol to suppress RANKL expression in osteoblasts. While these findings support atenolol as a therapy to prevent osteoporosis, ongoing studies will be necessary to

determine how atenolol influences bone density in vivo and investigate additional molecular and genetic mechanisms of bone loss prevention.

YAP and TAZ regulate adult bone formation and osteocytic bone remodeling

*YASAMAN MOHARRER[5], Ghazal Vahidi[2], DANIEL HORAN[3], TALA AZAR[4], Annemarie Lang[5], Alexander Robling[3], Xiaowei Liu[6], Chelsea Heveran[7], Joel Boerckel[6]. [5]University of Pennsylvania , [2]Montana state university , [3]Indiana University, United States, [4], [5]University of Pennsylvania , United States, [6]University of Pennsylvania, United States, [7]Montana state university, United States

Physical activity induces skeletal adaptation. However, the mechanotransductive mechanisms are unclear. Previously, using genetic methods, we found that the mechanosensitive transcriptional regulators, YAP and TAZ, regulate bone growth and osteocyte network formation. Here, we use global inhibition approaches to test the roles of YAP/TAZ in adult bone growth and osteocyte peri-lacunar remodeling.We injected 8-week-old male C57Bl/6J mice with DMSO or verteporfin (VP) for 2 weeks. VP inhibits YAP/TAZ-TEAD interaction. We evaluated bone formation by Calcein and Alizarin labeling, injected 7 days apart, and quantified the extent of mineralized bone surface (MS/BS), mineral apposition rate (MAR), and bone formation rate (BFR) in coronal and transverse tibial sections. Using a confocal microscope, we identified fluorochrome-labeled osteocytes lacuna, quantified the fluorescence intensity, and measured the lacunae mineral extent. By immunofluorescent staining on coronal sections, we checked if YAP/TAZ inhibition impacts other cell types. We quantified fracture toughness from the maximum and the yield load (KIc-max, KIc-initiation) by 3-point bending of notched femurs.YAP/TAZ inhibition significantly reduced periosteal and trabecular bone MS/BS, but modestly elevated endosteal MS/BS, though this difference was not statistically significant (Fig. 1 A and Fig. 1B). Reduced MS/BS values, without altered MAR indicate that YAP/TAZ inhibition reduced osteoblast recruitment without altering mineral deposition rate. Endomucin immunostaining showed a significant effect of VP treatment on bone marrow vascular morphology, area, and the number of endomucin+ blood vessels (Fig. 1C), highlighting the global nature of YAP/TAZ inhibition, and may explain the contrasts between endosteal and periosteal bone formation responses to YAP/TAZ inhibition. By fluorochrome labeling of osteocyte lacunae, we found that YAP/TAZ inhibition significantly reduced the intensity of the calcein-labeled lacuna, particularly in the anterior tibia, which experiences maximal tensile strains (Fig. 1D), indicating a possible interaction between YAP/TAZ signaling and strain on osteocyte peri-lacunar mineralization. While Kc-max and Kc-initiation values were similar between groups, VP-treated femurs exhibited greater heterogeneity.These findings implicate YAP/TAZ signaling in bone formation and peri-lacunar mineral dynamics, dependent on local activity-associated mechanical cues.

A Prototype High-Resolution Peripheral Quantitative CT Scanner With Photon Counting Detectors For Bone Loss Assessment In Osteoporosis

*Laura Cerbone[1], Russo Paolo[2], Antonio Sarno[2], Luigi Cimmino[2], Giovanni Mettivier[2]. [1]Scuola Superiore Meridionale - University of Naples Federico II, [2]INFN Naples, Italy

Background: While dual-energy X-ray absorptiometry bone represents a fundamental tool for osteoporosis diagnosis, a new technique is available for bone's low-dose imaging, i.e., high-resolution peripheral quantitative CT (HR-pQCT), providing quantitative imaging of the 3D structure of trabecular bone (e.g., in the distal tibia and radius), with an isotropic spatial resolution of 60 μm. We present the design of a new compact HR-pQCT prototype scanner (T4-QCT) for tibia and radius, based on a photon-counting energy-selective detector. T4-QCT scans could also be adopted for CT imaging of metacarpophalangeal finger joints, aiming to improve the characterization of soft and hard tissues.Material and methods: At variance with energy integrating detectors adopted in commercially available HR-pQCT scanners, T4-QCT employs hybrid pixel detectors consisting of a CdTe semiconductor pixel sensor and a Timepix4 readout circuit (448 × 512 square pixels of 55 μm), and a microfocus X-ray tube. Timepix4 spectral imaging performance allows measurement of the x-ray energy deposited in the detector by each interacting photon with a resolution of about 1 keV; this allows the discrimination of bone from soft tissues based on their energy-dependent attenuation, without the need for dual-energy scans. The proposed device will employ 3 Timepix4 CdTe (1-mm thick) pixel detectors in a row, in an offset-detector CT acquisition geometry, with a field of view of 10 cm diameter at the isocenter. This device will be compact and light, with a diameter of 70 cm and a weight below 50 kg.Results: The high granularity of the sensor can lead to an isotropic spatial resolution below 40 μm. CT scans using photon counting detectors effectively increase the image SNR and reduce the radiation dose to the patient. However, this spectral CT scanner's most relevant capability will be separating tissues that exhibit slight differences in densities and Zeff by taking advantage of the different dependence of attenuation coefficients from energy. In addition, the compactness of this scanner with respect to commercially available ones will allow for examining bedridden patients, which might be the case for those suffering from osteoporosis, bone fragility and fractures, and for scanning finger joints for signs of bone disease.Conclusions: T4-QCT is proposed as a new photon-counting scanner for spectral CT osteoporosis and rheumatoid arthritis diagnostic assessment in radius and tibia bone imaging scans.

Improved Fracture Discrimination in Patients With Systemic Lupus Erythematosus using DXA-derived 3D measurements of the Hip

*Edgar Wiebe[1], Elisa Celine Schilling[1], Dörte Huscher[2], Andriko Palmowski[1], Zhivana Boyadzhieva[1], Sandra Hermann[1], Tobias Alexander[1], Falk Hiepe[1], Burkhard Muche[1], Frank Buttgereit[3]. [1]Charité Universitätsmedizin, Dept. Rheumatology, Germany, [2]Charité Universitätsmedizin; Institute for Biometry and Clinical Epidemiology, Germany, [3]Charité Universitätsmedizin, Germany

Background:Patients with systemic lupus erythematosus (SLE) face an increased risk of osteoporosis and fragility fractures (FFx) which may not be adequately captured by areal bone mineral density (aBMD) measurement. Dual energy X-ray absorptiometry (DXA)-derived three-dimensional (3D) analysis has emerged as a promising method for evaluating femur bone structure, showing good correlation with quantitative computed tomography, which has demonstrated good predictive capabilities for fracture risk in postmenopausal non-SLE women.Objectives:We aimed to analyze the discriminative ability of DXA-derived 3D parameters of the femur compared to BMD and trabecular bone score (TBS) for pre-ex-

istent FFx in this SLE cohort.Methods:The prospective observational cohort study Rh-GIOP investigates bone health in patients >=18 years with inflammatory rheumatic diseases and current or prior GC treatment. This cross-sectional analysis assessed baseline visits of all SLE patients meeting the EULAR/ACR 2019 SLE classification criteria. DXA-derived 3D measurements of both femora were obtained using the software 3D-Shaper (v2.12, 3D-Shaper Medical, Barcelona, Spain). Logistic regression analysis was used to develop discrimination models incorporating DXA-based T-Scores, TBS, and 3D-Shaper to detect prevalent FFx, vertebral fractures (VFx), and non-vertebral fractures (NVFx). Area under the curve (AUC) values with 95% confidence intervals were calculated.Results:Baseline data from 110 SLE patients (92% female) were analyzed. The prevalence of FFx was 29%, with 10% having a VFx history. DXA-based T-Scores reached AUC values of 0.61 (0.49; 0.73), 0.47 (0.30; 0.64), and 0.61 (0.48; 0.74) for prevalent FFx, VFx, and NVFx, respectively. In comparison, 3D-Shaper showed better discrimination especially for VFx, with AUC values of 0.66 (0.54; 0.77), 0.77 (0.67; 0.87), and 0.64 (0.52; 0.76). A combined model of 3D-Shaper with DXA and TBS only slightly improved discrimination for FFx (0.67 (0.56; 0.78)) and VFx (0.78 (0.65; 0.91)), but not for NVFx: (0.63 (0.51; 0.75)). TBS alone or in combination with DXA did not enhance the discrimination model.Conclusion:In SLE patients, DXA-derived 3D parameters provide better discrimination of pre-existent fractures than DXA or TBS alone, particularly for VFx. Future longitudinal analyses will show whether these 3D-Shaper parameters can improve fracture prediction in clinical practice.

Comparative Short Term Recover And Functional Outcome Between Isolated Hip Fracture And Hip Fracture Coexisting With Osteoporotic Vertebral Compression Fracture *Ong-art Phruetthiphat[1], Wasin Kanokwongnuwat[2], Yodhathai Satravaha[3], Chaisiri Chaichankul[2], Pawin Gajaseni[2], Thawee Songpatanasilp[2]. [1]Phramongkutklao Hospital, Thailand. [2]Phramongkutklao hospital, Thailand. [3]Orthodontic department, Mahidol university, Thailand

Background: Fragility hip fractures are also correlated with high mortality, loss in disability-adjusted life year, and financial burden on the healthcare system. The 2 out of 3 osteoporotic vertebral compression fracture (OVCF) is asymptomatic and is common seen in the elderly population. However, current study has not identified the association of hip fracture and OVCF including the recovery and functional outcome. The purpose of this study was to identify a comparison of short-term recovery and functional outcome between Isolated hip fracture and hip fracture coexisting with osteoporotic vertebral compression fracture. Method: A prospective study was performed between 2019 and 2020. The inclusion criteria were those patients with femoral neck fractures or intertrochanteric fractures over 60 years old underwent bipolar hemiarthroplasty or Proximal Femoral Nail Anti-rotation (PFNA), respectively. 81 Patients were classified into 2 groups: Isolated hip fracture (Isolated group) (30.9%), and combined hip fracture and OVCF (Combined group)(69.1%). The severity of OVCF was evaluated by Genant classification. Time Up and Go Test (TUG) was evaluated at 2 weeks, and 6 weeks. In addition, the functional outcome assessed by Harris Hip Score (HHS) was performed at 6 months, and one year. The association of the severity of OVCF, TUG, and HHS were also evaluated.Result: There was no difference in age, gender, comorbidity, ASA class, CCI, and the percentage of intertrochanteric fractures and femoral neck fractures in both groups, as well as the operative parameters. Hip BMD and spine T-score BMD in the combined group was significantly lower than the Isolated group (p = 0.03 and p = 0.033, respectively). The length of hospital (p = 0.022) was significantly shorter, and the 6 weeks TUG (p = 0.042) was significantly lower in the isolated group compared to the combined group. Moreover, the 6 months HHS, and one year HHS in the isolated group was significantly higher than the combined group (p = 0.007 and p =0.005, respectively). In term of severity of OVCF (Grade 1-2 vs grade 0 and grade 3 vs grade 0), the higher grade was significantly lower 6 months HHS (p = 0.014 and p = 0.012, respectively).ConclusionsThe elderly hip fracture combined with OVCF had significantly longer hospital stay, longer time to recover, and worse functional outcome than the isolated group. The severity of OVCF was significantly associated with the worse outcome. This combined group needs more attention during the rehabilitation program.

Longitudinal Changes of Cortical and Trabecular Bone Characteristics Associated with Declines in Failure Load in Older Men *John Schousboe[1], Lisa Langsetmo[2], Sheena Patel[3], Andrew Burghardt[4], Peggy Cawthon[5], Mary Bouxsein[6], Nicole Sekel[7], Kristine Ensrud[8]. [1]Park Nicollet Clinic HealthPartners Institute University of Minnesota, [2]University of Minnesota, United States, [3], [4]University of California, San Francisco, United States. [5]California Pacific Medical Center, United States. [6]Beth Israel Deaconess Medical Center, Harvard Medical School, United States. [7]University of Pittsburgh, United States. [8]University of Minnesota and Minneapolis VA Health Care System, United States

Background: Trabecular and cortical bone microstructure are key determinants of fracture resistance. However, the changes in bone microarchitectural parameters that contribute to declines in failure load at older ages are uncertain. Our objective was to estimate the associations of changes in cortical and trabecular bone parameters with changes in failure load of the distal radius and tibia in older men.Methods: 150 men mean (SD) age 83.0 (3.1) years attending the 4th examination at the Pittsburgh and Palo Alto sites of the Osteoporosis Fractures in Men (MrOS) study had high resolution quantitative peripheral computed tomography (HR-pQCT) scans of the distal radius and distal tibia, and had these repeated at the 5th visit a mean (SD) 6.9 (0.6) years later. We used 3D registration to align the baseline and follow-up scans. Cortical parameters were volumetric BMD (Ct.BMD) and thickness (Ct.Th), porosity (Ct.Po), and area (Ct.Ar). Trabecular parameters were vBMD (Tb.BMD), number (Tb.N), and separation (Tb.Sp). Failure load was calculated using finite element analysis and annual changes in failure load, cortical, and trabecular parameters were calculated. We used linear regression to estimate the association of failure load change and each bone parameter change separately, adjusted for age and study site. All parameters with a univariate association with failure load change at p-value <0.10 were included multivariable regression models.Results: After adjustment for age and center, greater losses in Ct.BMD and Tb.BMD were each associated with greater loss of failure load at both skeletal sites. Surprisingly, a decrease in Ct.Po was associated with greater loss of failure load at both skeletal sites (Table). In multivariable analyses, decreases in Ct.BMD, Tb.BMD, and Ct.Po were associated with greater loss of failure load, after consideration of age, center and each other. Effect size was strongest for Ct.BMD. Changes of Ct.Th, Ct.Ar, Tb.N, and Tb.Sp, were not associated with failure load change at either skeletal site.Conclusion: Longitudinal declines in failure load at both the distal tibia and radius in older men are driven especially by declines in Ct.BMD and to a lesser degree by declines in Tb.BMD. We also saw a paradoxical association of changes of Ct.Po with changes of failure load, in the opposite direction of what we hypothesized. Further research is needed to better understand these associations.

Table: Multivariable-Adjusted Associations[a] of Cortical and Trabecular Bone Parameter Changes with Magnitude of Failure Load Loss

Bone Parameter	Effect Size[b] (95% C.I.)	
	Distal Tibia	Distal Radius
Cortical BMD	0.64 (0.54, 0.74)	0.54 (0.42, 0.66)
Cortical Porosity	-0.20 (-0.29, -0.11)	-0.23 (-0.35, -0.12)
Trabecular BMD	0.23 (0.14, 0.33)	0.24 (0.10, 0.38)
R-squared[c]	0.70	0.58

Assessment of bone health through a photoacoustic quantitative ultrasound (PAQUS) apparatus: a preliminary phantom and clinical study *Zhanpeng Xu[1], Duane Kaufman[2], Rich Hogle[2], Dave Nelson[2], Conor Locke[1], Dara Geva[1], DeAndre Jamison[1], Xueding Wang[1], Rich Morris[2], Kenneth Kozloff[1]. [1]University of Michigan, United States. [2]IF, LLC, United States

Osteoporosis is a significant degenerative disease characterized by loss of bone density and strength, resulting in greater susceptibility to fracture. Development of technologies that enhance early detection of osteoporosis-related changes in bone may help provide timely intervention, reducing fractures and improving overall quality of life. Clinical diagnosis relies on evaluation of bone mineral density (BMD) by DEXA, which provides an incomplete measure of fracture risk. Photoacoustic (PA) imaging is an emerging technology that combines the advantages of high optical contrast and deep ultrasound penetration for non-invasive and non-ionizing quantitative measurement. Spectral information derived from PA reflects a combination of bone microstructure, BMD, and chemical composition that may be useful for evaluating changes in bone health associated with disease or treatment.In the work, a novel photoacoustic quantitative ultrasound (PAQUS) apparatus was developed

for in vivo assessment of the calcaneus. Using 3D printing with dental crown resin, we first made lattice-shaped cubic phantoms of varying density by holding trabecular number constant and varying trabecular thickness (0.630, 0.597, 0.548 mm), resulting in bone volume fractions (BVF) of 0.295, 0.274 and 0.245. Phantoms were then infiltrated with a marrow-mimicking substitute. PA spectra were collected (690-950 nm) and normalized to 800 nm. PA absorbance at 740 nm (hemoglobin) and 930 nm (lipid) were significantly different ($p<0.05$) across phantoms. Next, we created two anatomic phantoms based on a human calcaneus nano-CT volumetric image, and artificially eroded the trabecular structure on one to reduce BVF by 32.5%, mimicking osteoporosis-mediated bone loss. Phantoms were imaged repeatedly and also significantly differed at 740 and 930 nm ($p<0.01$). Lastly, in vivo bilateral PA imaging was conducted at the calcaneus on 32 female Caucasian subjects (20-74 yrs). A significant difference ($p<0.05$) in PA absorption was observed at 740 nm between younger (50 yrs) subjects. Together, results from this preliminary phantom and clinical study demonstrate initial feasibility of PAQUS in assessing human bone mass in a non-ionizing, non-invasive and cost-effective way. Using our multi-spectral approach, PAQUS may provide novel data that may reflect metabolic and compositional changes associated with osteoporosis or response to treatment earlier than conventional measures of BMD alone.

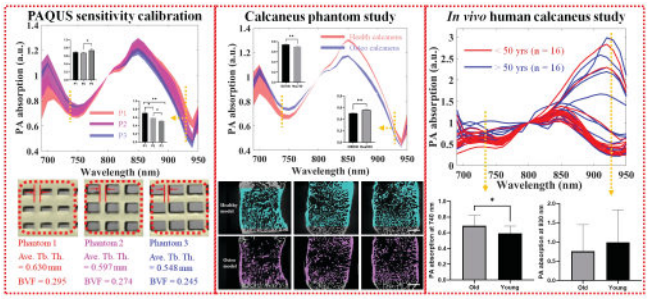

Figure 1. PAQUS sensitivity calibration: Cubic lattice phantoms with different trabecular thicknesses (bone volume fractions), 3D printed from dental resin and infiltrated with marrow substitute, were assessed by PAQUS. PA absorption spectra are plotted as ranges of "mean ± s.d." and differentiated at 740 and 930 nm by unpaired t test. Calcaneus phantom study: Anatomic calcaneal 3D printed phantoms were similarly evaluated, and significant differences of PA spectra were found at 740 and 930 nm. *In vivo* human calcaneus study: *In vivo* assessment of human calcaneus showed distinct age-associated differences at 740 nm. Error bars represent standard error of mean (SEM). *p < 0.05, **p<0.01.

Cold is Associated with Lower Bone Strength in the Midshaft Femur of Medieval Humans *Miranda Cosman[1], Maureen Devlin[1]. [1]University of Michigan, United States

Chronic cold stress decreases bone mass through sympathetic nervous system (SNS) activation in animal models, and is a potential risk factor for bone loss in humans. To test the effects of chronic cold exposure on the skeleton, in this study we used an archaeological sample of Medieval humans from different latitudes as a natural experiment. We studied adults of European genetic ancestry from two sites: Haffjarðarey, Iceland (mean high 45.3°F/low 36.3°F), interred from 1200-1563 CE, and Mistihalj, Bosnia and Herzegovina (mean high 65.8°F/low 52.3°F), interred from 1300-1500 CE, housed at the Peabody Museum at Harvard University. We hypothesized that bone mass would be lower at Haffjarðarey (cold) vs. Mistihalj (warm). Femoral midshaft cortical bone cross-sectional geometry was obtained via computed tomography (45-64 µm). Scans were reconstructed and segmented in Dragonfly (Object Research Systems), then measured using the BoneJ plugin (Domander et al., 2021) in Fiji (2.14.0). We assessed cortical bone area (BA, mm2), cortical thickness (Ct.Th, mm), maximum and minimum area moments of inertia (Imax and Imin, mm4), and the polar moment of inertia (J, mm4). Results indicate that bone strength was higher at the warmer Mistihalj than at the colder Haffjarðarey. In females, BA (+13%, $p<0.07$), Imax (+27%, $p=0.027$) and J (+23%, $p=.047$) were higher at Mistihalj; body mass (estimated by femoral head diameter), Ct.Th, and Imin did not differ between sites. In males, BA (+22%, $p=.001$), Imax (+34%, $p=0.004$) and J (+26%, $p=.014$), and estimated body mass (+10%, $p=0.041$) were higher at Mistihalj; Ct.Th and Imin did not differ between sites. After adjustment for body mass, significance remained for BA ($p=0.028$) and trended for Imax ($p=0.063$). We also observed significant cortical porosity, indicative of bone turnover, in ~75% of femora from Haffjarðarey vs. ~50% of femora from Mistihalj. These results indicate bone mass was lower in Europeans in Iceland compared to counterparts in Bosnia and Herzegovina, and supports the hypothesis that chronic cold is deleterious to bone mass. Ongoing analyses include trabecular bone microarchitecture.

[4]Deputy Director of Rehabilitation Medicine, Instituto Nacional de Rehabilitacion "Luis Guillermo Ibarra Ibarra", Mexico City, Mexico, Mexico

Introduction: Fracture Liaison Services (FLS) have been shown to be effective in preventing secondary fragility fractures. A previous study by the same group identified a significant gap in the diagnosis and treatment of osteoporosis in patients with fragility fractures. In early 2020, an FLS program was initiated at our hospital. However, its implementation was interrupted by unexpected events, including the COVID-19 pandemic and a new healthcare system in the country. Nevertheless, the program was implemented.Objective: The objective of this study was to examine how the frequency of diagnosis and treatment of osteoporosis changed after the setting of an FLS unit during the first year of its establishment.Materials and Methods: This was a descriptive study conducted by retrospective analysis of one year after the implementation of an FLS. Ethical Considerations: This project is part of the "Impact of a Secondary Prevention Unit for Osteoporosis Fracture Prevention in a Third-Level Institution in Mexico City" project funded by the National Research Council of Mexico through the Health Research Fund, number A3-S-47397. This study was registered as Protocol No. 28/19/AC. The study included patients aged 50 years and above diagnosed with acute low-energy (fragility) fractures of the hip, distal radius, and proximal humerus.Results: A total of 368 patients were included in the study, with a mean age of 78.35 +/- 11.58 years. Of the total, 271 (73.6%) had hip fractures, 66 (17.9%) had distal radius fractures, and 29 (7.9%) had proximal humerus fractures. Of these, only 26 (7.1%) had a previous diagnosis of osteoporosis. During hospitalization, 147 patients (39.9%) were diagnosed with osteoporosis. Of these, 274 (74.5%) received some form of pharmacologic treatment. Supplementation with calcium and vitamin D was indicated in 96 patients (26.1%), while non-pharmacological management, including a calcium-rich diet, exercise, and fall prevention, was indicated in 95 patients (25.8%). At one-year follow-up, 88 (23.9%) of those diagnosed and treated in the hospital were on pharmacologic therapy, 128 (34.8%) were on supplementation, and 131 (35.7%) were on non-pharmacologic therapy.Conclusions: This study shows that despite adverse contexts, the implementation of an FLS significantly increased the proportion of patients diagnosed and treated for osteoporosis after a fragility fracture.Conflict of interest. None.

The Association of Bone Mineral Density (BMD) with incident Major Osteoporotic and Hip Fractures Varies by Body Mass Index (BMI) *John Schousboe[1], Neil Binkley[2], William Leslie[3]. [1]Park Nicollet Clinic HealthPartners Institute University of Minnesota, . [2]University of Wisconsin, Madison, United States. [3]University of Manitoba, Canada

Background: Increased BMI and abdominal fat mass increase the precision error of bone densitometry measurement, and may adversely affect its accuracy as well. Our aim was to estimate if the association of femoral neck, total hip, and/or lumbar spine BMD is modified by BMI. We hypothesized that the association of BMD with incident major osteoporotic and hip fractures is weaker among very obese compared to individuals with normal BMI. Methods: Our study population was 82,431 individuals (mean [SD] age 64.8 [11.0] years, 90% female) who had a fan-beam DXA-BMD test in the province of Manitoba between 1998 and 2018. BMI and other predictors were assessed on the date of the BMD test and incident fractures ascertained through linked health claims over a mean (SD) follow-up of 8.5 (5.2) years. Proportional hazards models were used estimate the associations of femoral neck, total hip, and lumbar spine BMD with incident major osteoporotic and hip fractures, adjusted for age and sex and then additionally for FRAX risk factors, use osteoporosis therapy during any part of the follow-up period, tissue fat and soft tissue thickness (at the BMD skeletal site). Statistical differences in strength of association of BMD with incident fractures between BMI categories were tested (p-interaction, T-score*BMI category).Results: The associations of femoral neck and total hip BMD with incident fractures were as strong for those with high or very high BMI as for those with normal BMI (table), but were weaker for underweight individuals (BMI < 18.5 kg/m2) (Table). The associations of lumbar spine BMD with incident fractures did not vary by BMI.Conclusion: BMD is as strong a predictor of major osteoporotic fractures and hip fractures in even very obese individuals compared to those with normal BMI. However, femoral neck and total hip BMD are weaker predictors of these fractures in underweight individuals. Further research is needed to delineate the mechanisms and reasons for these weaker associations.HIPC File Number: 2016/2017-29?

Frailty is a Predictor of Incident Osteoporotic Fractures in Veterans with Rheumatoid Arthritis *Katherine Wysham[1], Hannah Brubeck[2], Aaron Baraff[2], Punyasha Roul[3], Namrata Singh[4], James Andrews[4], Grant Cannon[5], Gary Kunkel[5], Ted Mikuls[6], Bryant England[6], Dolores Shoback[7], Patricia Katz[8], Jose Garcia[9], Ariela Orkaby[10], Joshua Baker[11]. Crescenz VA Medical Center, United States

Purpose: Frailty occurs prematurely in rheumatoid arthritis (RA). In this study we evaluated whether frailty predicted incident osteoporotic fractures in Veterans with RA using an externally validated frailty index.Methods: Data were from the Veterans Affairs Rheumatoid Arthritis (VARA) Registry 1/2003-12/2021. Baseline frailty was calculated using the VA Frailty Index (VAFI)1, which is based on diagnostic and CPT codes categorized into 31 deficits including morbidity, function, mood, cognition and geriatric syndromes. Osteoporotic fractures were identified by diagnostic and procedure codes and validated by chart review. High-trauma, periprosthetic and pathologic fractures related to cancer were excluded. Multivariable Cox regression was used to evaluate the relationship between baseline frailty and incident osteoporotic fracture, adjusting for baseline age, sex, race, smoking status, antibody status and prior osteoporotic fracture; and time-varying body mass index, disease activity, prednisone use and RA medication use. The same model was used to evaluate the relationship between baseline frailty and the risk of specific fracture type (extremity, rib, spine, hip and pelvis).Results: Veterans (N=2,930) had a mean age of 64+/-11 years. Cohort characteristics are detailed in Table 1. There were higher rates of baseline frailty in the fracture group (25% vs 17% mild frailty, 10% vs 7% moderate frailty, and 5% vs 2% severe frailty). Over the 21,800 person-years of observation, 240 incident osteoporotic fractures occurred (79 extremity, 58 rib, 47 spine, 43 hip and 13 pelvis). In the multivariable Cox model, prefrail, mild, moderate and severe frailty each had significantly increased risk of incident osteoporotic fracture compared to those who were robust (aHR [95%CI]:1.44 [1.02-2.05], 2.32 [1.56-3.45], 3.30 [2.00-5.46] and 4.92 [2.48-9.80]; all p<0.05, respectively). The relationship between baseline frailty level and incident fracture did not differ significantly by fracture type.Conclusions: Baseline frailty is associated with incident osteoporotic fractures in Veterans with RA in a dose-dependent fashion. We did not find significant differences in the relationship between baseline frailty and risk of fracture by fracture type. Frailty measurement in RA using the VAFI, a validated, automated tool, may prove to be useful in identifying Veterans at high risk for osteoporosis and fractures.1Orkaby AR et al. J Gerontol A Biol Sci Med Sci. 2019

Does long-term antiresorptive administration lead to atypical fractures at other skeletal sites excluded from the ASBMR atypical femur fracture (AFF) case definition? A systematic review *Lucy Collins[1], Alec Ronan[1], Peter Ebeling[2], Vivian Grill[3], Hanh Nguyen[4]. [1]Department of Endocrinology and Diabetes, Western Health, Victoria, Australia, Australia. [2]Department of Medicine, School of Clinical Sciences, Monash University, Victoria, Australia; Department of Endocrinology, Monash Health, Victoria, Australia, Australia. [3]Department of Endocrinology and Diabetes, Western Health, Victoria, Australia; Department of Medicine, The University of Melbourne, Victoria, Australia, Australia. [4]Department of Endocrinology and Diabetes, Western Health, Victoria, Australia; Department of Medicine, School of Clinical Sciences, Monash University, Victoria, Australia, Australia

BackgroundOsteoporosis affects > 1.3 million Australians. Bisphosphonates and denosumab are approved treatments for osteoporosis with the rare complications of jaw osteonecrosis and AFFs. Cases of AFFs were first reported in 2005, highlighting a state of significantly suppressed bone turnover on biopsy (1). In 2010 and 2013, an American Society of Bone and Mineral Research (ASBMR) Task Force proposed a case definition for these atypical fractures affecting the femoral diaphysis (2, 3). Subsequently, reports of similar atypical fractures at other skeletal sites have been published.AimWe aimed to systemically identify cases of atypical fractures, excluded from the ASBMR AFF case definition in patients receiving anti-resorptive medication (duration > 3 years).MethodA structured search of electronic databases, including PubMed, Medline, Embase, Cochrane and Web of Science and hand-searching of conference abstracts/reference lists was completed. All full-text articles written in English describing atypical fractures were screened for: 1) cases of atypical fractures, excluded from the ASBMR AFF case definition in patients (aged > 18 years) receiving long-term antiresorptive medication, 2) cases published 2005 - 2023.Results7954 citations were identified. 65 articles fulfilled the inclusion criteria. Fractures were more common in females (112/120, 93%). Most frequent fracture sites included the ulna (n=32), tibia (n=12), pelvis (n=10), vertebral pedicle (n=8), sacrum (n=6) and femoral neck (n=5). One atypical fracture was reported in a monogenetic bone disorder (hypophosphatasia). Fractures were commonly atraumatic, with prodromal pain and typically transverse, non-comminuted with evidence of cortical thickening and sclerosis. Non-union was more frequent following conservative management. In most cases, anti-resorptive medication was ceased (41/47, 87%). ConclusionAtypical fractures at sites other than the femoral diaphysis in patients receiving long-term anti-resorptive treatment are important to recognise and may provide insights into the pathogenesis of AFF. A review of the current AFF case definition could be undertaken to include other skeletal sites.

Pharmacologic inhibition of HIF2 prevents trabecular bone loss in ovariectomized mice *Giulia Lanzolla[1], Elena Sabini[1], Mohd Parvez Khan[1], Brittany Laslow[1], Dian Wang[1], Xiaowey Sherry Liu[1], Ernestina Schipani[2]. [1]Department of Orthopaedic Surgery, University of Pennsylvania, Perelman School of Medicine, Philadelphia, 19104, PA, USA, United States. [2]University of Pennsylvania,

Cells of the osteoblast lineage are exposed to a gradient of oxigenation in the adult bone marrow. The transcription factors Hypoxia Inducible Factor 1 (HIF-1) and HIF-2 are key mediators of the cellular response to hypoxia. Loss of HIF2 in the osteoblast lineage promotes bone formation and augments bone mass. Therefore, HIF2 could represent a novel therapeutical target for the treatment of low bone. The study was aimed at evaluating whether the pharmacologic inhibition of HIF2 prevents bone loss in ovariectomized mice. Eight-week-old female mice (FVB/N) were ovariectomized or sham-operated. Next, mice were randomized to be treated with either PT2399 (50 mg/kg), a selective inhibitor of HIF2, or with vehicle by oral gavage, twice daily for 5 weeks. As expected, a significant increase in body weight and a decrease in uterus weight were observed 6 weeks upon ovariectomy. The trabecular bone compartment in both vertebral bodies and distal metaphysis of femurs was analyzed by micro-CT and histomorphometry. Micro-CT analysis showed a significant decrease in bone volume/tissue volume ratio (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), and bone mineral density (BMD) in OVX mice treated with vehicle compared to sham-operated, whereas trabecular spacing (Tb.Sp) was increased. More importantly, no difference was detectable in any of the parameters listed above between OVX mice treated with PT2399 and sham-operated treated with vehicle. Histomorphometry confirmed micro-CT data. Furthermore, number of osteoblasts over bone surface (Ob.N/BS) was significantly lower in vehicle-treated OVX mice compared to sham-operated. This decrease was prevented by PT2399 administration. Although osteoclast number over BS (Oc.N/BS) did not differ between the four groups, the BS/BV ratio, which is an index of resorptive activity, was significantly higher in OVX mice treated with vehicle compared to sham-operated. PT2399 treatment again normalized this parameter in OVX mice. Taken together, PT2399 fully prevented trabecular bone loss due to ovariectomy in mice, thus representing a new potential anabolic agent to be tested for treating postmenopausal osteoporosis. Modest anemia occurred in mice treated with PT2399, likely due to reduction of renal EPO, which is a direct downstream target of HIF2. Further studies are needed to target PT2399 specifically to bone to prevent anemia and clarify the mechanisms by which PT2399 prevents bone loss.

Bisphosphonate Use and Mortality in Olmsted County, MN, USA: A Population-Based Analysis *Richard Lindsey[2], Alanna Chamberlain[2], Elizabeth Atkinson[2], Jad Sfeir[2], Sundeep Khosla[3]. [2]Mayo Clinic, . [2]Mayo Clinic, United States. [3]Mayo Clinic College of Medicine, United States

Bisphosphonates are the most common drugs used to decrease fracture risk in patients with osteoporosis. There has been considerable interest regarding whether bisphosphonates as a class, and zoledronic acid (ZA) in particular, may have broader non-skeletal beneficial effects. Several clinical studies have suggested associations with reduced incidence of cancer, cardiovascular disease, and all-cause mortality. Thus, to address this issue, this study used population-based data from the Rochester Epidemiology Project (REP). The REP allows access to medical records of a wide selection of community members in Olmsted County (Minnesota, USA) to allow population-based analysis of health data in this community over time. We included participants who were at least 50 years of age and were prescribed a bisphosphonate between 2005 and 2021. Individuals who had prior osteoporosis therapy or history of cancer were excluded. We used Cox models adjusting for age, sex, and Elixhauser score to compare mortality of those who used bisphosphonates to propensity score-matched referents. A total of 3,825 patients prescribed bisphosphonates were identified (mean age 70.5 [SD 10.4] years, 85.4% female, 88.9% Caucasian). Alendronate was the primary bisphosphonate used, accounting for 86% of prescriptions, followed by risedronate (7.3%) and ZA (3.6%). Other bisphosphonates included etidronate, ibandronate, and pamidronate. Overall, no significant difference in mortality was observed between those on bisphosphonates and referents (see Table 1). This lack of an effect was consistent when analyzing only those who used alendronate or ZA, although the number of ZA users in this cohort was small (n = 139 out of 3,825). The only statistically significant effect on mortality was observed among males who used ZA (hazard ratio 2.80 [95% CI 1.17-6.69]). The lack of an association between bisphosphonate use and mortality is consistent with some previous data. However, several other observational studies similar in design to this study have suggested a mortality benefit to bisphosphonate use. Furthermore, there is a growing body of mechanistic animal data suggesting ZA may have anti-aging effects, in part by targeting senescent cells. Thus, observational studies may not be able to fully address this question, and randomized clinical trials are likely needed to determine whether bisphosphonate use provides a clinically meaningful mortality benefit.

Table 1

Bisphosphonate	Hazard Ratio All (95% CI)	Hazard Ratio Male (95% CI)	Hazard Ratio Female (95% CI)
All	1.07 (0.98–1.18)	1.20 (0.98–1.48)	1.04 (0.94–1.16)
Alendronate	1.03 (0.93–1.14)	1.06 (0.85–1.34)	1.02 (0.91–1.14)
Zoledronic Acid	1.83 (1.11–3.00)	**2.80 (1.17–6.69)***	1.48 (0.80–2.75)

Risk of all-cause mortality in bisphosphonate users compared to propensity score-matched referents. Adjusted for age, sex, and Elixhauser score.

2023 Clinical Practice Guideline Update for Management of Osteoporosis and Fracture Prevention in Canada *Suzanne Morin[1], Sidney Feldman[2], Larry Funnell[3], Lora Giangregorio[4], Sandra Kim[5], Heather McDonald-Blumer[2], Rowena Ridout[6], Nancy Santesso[7], Wendy Ward[8]. [1]McGill University, Canada. [2]University of Toronto, Canada. [3]Patient Partner, Canada. [4]University of Waterloo, Canada. [5]University of Toronto, Women's College Hospital, Canada. [6]Toronto Western Hospital, Canada. [7]McMaster university, Canada. [8]Brock University, Canada

PurposeOver 2 million Canadians live with osteoporosis, a disease that increases the risk for fractures. Fractures result in excess morbidity and mortality, decreased quality of life and loss of autonomy. This Canadian guideline update, to be published on October 10th 2023 in the Canadian Medical Association Journal, is intended to assist healthcare professionals in the delivery of care to optimize skeletal health and prevent fractures in postmenopausal females and in males 50 years of age and older.MethodsWe followed the Grading of Recommendations Assessment, Development and Evaluation (GRADE) Framework and quality assurance as per AGREE II quality and reporting standards. Primary care physicians and patient partners were represented at all levels and throughout the entire process to ensure relevance to target users. The process for managing conflicts of interest was developed prior to and continued throughout the guideline development, informed by the Guideline International Network principles. We considered benefits and harms, patient values and preferences, resources, equity, acceptability and feasibility when developing recommendations; the strength of each recommendation was assigned according to the GRADE Framework. RecommendationsThe 25 recommendations and 10 good practice statements are grouped under the sections of exercise, nutrition, fracture risk assessment and treatment initiation, pharmacologic interventions, duration and sequence of therapy, and monitoring. The management of osteoporosis should be guided by the patient's risk of fracture based on clinical assessment and using a validated fracture risk assessment tool. Exercise, nutrition and pharmacotherapy are key elements of the management strategy for fracture prevention, and should be individualized.InterpretationThis guideline aims to empower healthcare professionals and patients to have meaningful discussions on the importance of skeletal health and

fracture risk across older adulthood. Identification and appropriate management of Canadians with skeletal fragility can reduce fractures, and preserve mobility, autonomy and quality of life in this population.

Longitudinal Tracking of Patient-Level Indicators Characterizing Osteoporosis Care after Fragility Fracture in U.S. Medicare Fee-for-Service Beneficiaries (2017-2019) Confirms the Osteoporosis Treatment Gap and Provides Insights for Needed Improvement *Jennifer Todd[1], Adrienne Lovink[2], Barton Jones[4], Benjamin Lewing[4], Scott Robinson[4], Cesar Libanati[5]. [1]UCB Pharma, United States. [2]Trinity Life Sciences, United States. [4]Inovalon, United States. [4]Inovalon, United Kingdom. [5]UCB Biopharma srl,

Purpose:Despite increased secondary fracture prevention efforts, most patients experiencing a fragility fracture do not receive treatment (Tx) for underlying osteoporosis (OP). This study aimed to characterize the state of post-fracture care (PFC) in the U.S. by longitudinally tracking a comprehensive set of patient-level metrics inclusive of Tx.Methods:Patients >50 years with a fragility fracture claim from 2017-2019 were identified in Medicare Fee-for-Service (FFS) claims data. Qualifying fractures were identified using ICD-10 codes aligned to comprehensive inclusion/exclusion criteria. Prior non-symptomatic vertebral and traumatic fractures, and fractures associated with cancer or Paget's disease, were excluded. Patients were required to have continuous health plan enrollment with either medical or medical+pharmacy (Rx) coverage during a 6-month lookback period and >=12 months after index fracture (IF). The medical+Rx population was used to calculate Tx metrics due to a lack of Rx data in the medical only group.Results:We identified 1,941,902 patients who experienced a fragility fracture; 71.5% were female. Only 5.8% of all patients and 6.7% of women received a DXA within 3 months of IF. OP was diagnosed based on presence of a diagnosis code in <4% of patients in each group. ~30% of patients in each group experienced a subsequent fracture within 2 years of IF. For the continuous medical+Rx population, Tx initiation within a year was 12.1%: 0.5% received an osteoanabolic (OA), 11.7% received an antiresorptive (AR) and 0.1% received both. Only 3.4% received an OA first; 96.6% received an AR first. Tx initiation rates were slightly higher for women (14.9%); other Tx patterns were similar. Tx persistence at 1 year among those initiating Tx was ~31% in both groups (Table).Conclusion:This analysis confirms the majority of Medicare FFS patients who experienced fragility fractures did not receive Tx to prevent additional fractures. Additionally, it underscores the opportunities to intensify focus on strategies that address pressing gaps in care for these patients: First, investing in PFC by increasing programs and patient reach while ensuring appropriate coding of OP. Second, ensuring care provided to patients aligns to evidenced-based guidelines (risk stratification, choice of OP therapy). Last, implementing simple, effective strategies to improve adherence to interventions with the highest probability to prevent additional fractures.

Table: Selected population characteristics and study results in patients who experienced osteoporosis-related fractures in Medicare FFS (2017–2019)

	All Patients *n = 1,941,902 (100.00%)*		Female Patients *n = 1,388,835 (71.52%)*	
Information on Index Fracture Population (2017-2019) - Total Population (n,%)				
Age (n,%)	1,941,902	100.00%	1,388,835	100.00%
50-64	187,388	9.65%	109,512	7.89%
65-74	669,439	34.47%	459,028	33.05%
75-84	607,580	31.29%	440,079	31.69%

Humerus	234,447	12.07%	168,102	12.10%
Other	818,645	42.16%	539,569	38.85%
Study Results - Total Population (n,%)				
DXA[a]				
DXA within 3 months of index fracture (IF)	113,294	5.83%	93,603	6.74%
DXA within 12 months of IF	289,949	14.93%	253,234	18.23%
Coded Diagnosis of Osteoporosis (OP)[b]				
Presence of OP diagnosis code within 6 months of IF	48,705	2.51%	40,564	2.92%
Presence of OP diagnosis code within 12 months of IF	62,896	3.24%	52,662	3.79%
Subsequent Fractures[c]				
Subsequent fracture within 1 year of IF	376,535	19.39%	288,648	20.78%
Subsequent fracture within 2 years of IF	466,207	28.23%	360,190	30.24%
Study Results - Population with Continuous Health Plan Enrollment for Medical+Rx (n, %)				
	All Patients *n = 1,372,110 (100.00%)*		**Female Patients** *n = 1,006,434 (73.35%)*	
Treatment (Tx) Initiation[d]				
Any Tx within 12 months of IF	165,411	12.06%	149,627	14.87%
Both OA and AR Tx within 12 months of IF	1,333	0.10%	1,225	0.12%
Any osteoanabolic (OA) Tx within 12 months of IF	6,453	0.47%	5,796	0.58%
Any antiresorptive (AR) Tx within 12 months of IF	160,291	11.68%	145,056	14.41%
Osteoanabolic first (of those initiating Tx within 12 months of IF)	5,669	3.43%	5,073	3.39%
Antiresorptive first (of those initiating Tx within 12 months of IF)	159,742	96.57%	144,554	96.61%
Treatment (Tx) Persistence[e]				
Persistence on Tx ≥ 12 months (of those initiating Tx)	51,571	31.18%	47,546	31.78%

[a]Patients receiving DXA after index fragility fracture within specified time. [b]Determined by presence of an ICD-10-CM diagnosis of OP on at least 1 inpatient or 2 outpatient claims during follow-up period. Date of first OP code used to determine time to diagnosis. [c]All fracture types reported due to complexity associated with applying detailed inclusion and exclusion criteria at this stage. For 2-year metric, the population with continuous enrollment for medical was used (1,651,459 total and 1,191,104 for women). [d]Patients counted as treated only in the presence of at least 1 script/administration of OP treatment during the 12 months after IF. Categorized into the following Tx types: OA or AR. [e]Stability on therapy defined based on HCP-administered doses and/or doses supplied per pharmacy transactions (excluding abandonment). Differential dosing based on dosing schedule for each drug considered. Medication possession ratio (MPR) = totally day supply (based on any defined pharmacological treatment) divided by time under evaluation (12 months). MPR ≥ 0.80 considered persistent. DXA: dual energy x-ray absorptiometry; ICD-10-CM: ICD-10 Clinical Modification; OP: osteoporosis; IF: index fracture; Tx: treatment; OA: osteoanabolic; AR: antiresorptive; HCP: healthcare professional; MPR: medication possession ratio.

Therapeutic Potential of IL-3 in Ovariectomy-Induced Osteoporosis *Shubhanath Behera[1], Juilee Karhade[1], Garima Pandey[2], Arpita Prasad[1], Adrita Guha[1], Krishna Ezhuthachan[1], Mohan R Wani[1]. [1]National Centre for Cell Science, India. [2]National Centre for Cell Science, Pune, India

IL-3, a cytokine produced by activated T lymphocytes is known to promote the proliferation, differentiation, and survival of hematopoietic stem cells. We have previously reported that IL-3 exhibits both anti-osteoclastic and pro-osteoblastic activity in vitro. We have also shown that IL-3 prevents osteoporotic bone loss in vivo in mice when injected at osteopenic stage. However, the therapeutic potential of IL-3 is not yet delineated. In the current study, we evaluated the therapeutic potential of IL-3 in fully developed osteoporosis in C57BL/6J female mice. IL-3 was administered after 30 days of ovariectomy for the duration of 30 days. At day 60, all mice were euthanized, and bone samples were collected for RNA isolation and μ-CT scanning to assess the alterations in the skeletal structure. We observed that IL-3 significantly improved various skeletal parameters, including femur trabecular BMD; and BV/TV, Tb.Sp., Tb.N., SMI and Conn.Dn. etc. Three-dimensional images of femur trabecular bone showed reversal of bone loss (Figure 1). Moreover, IL-3 showed considerable enhancements in tibial trabecular BV/TV, Tb.N., and Conn.Dn., and displayed improvements in Tb.Sp. and BMD in the tibial trabecular bone region. Considering that bone formation is of paramount importance in the therapeutic context, we examined various signaling molecules associated with osteoblast differentiation and mineralization. Analysis of femur and tibia bones from the IL-3 treated mice revealed an upregulation in the mRNA expression of RUNX2, osterix, osteopontin, osteocalcin, alkaline phosphatase, and collagenase type I. Importantly, in IL-3 knockout mice, we found a significant reduction in bone volume, trabecular BMD, and several other structural skeletal parameters in both male and female mice compared to the wildtype mice. These results indicates the crucial role of IL-3 in maintaining bone homeostasis. Taken together, our results strongly suggest that IL-3 holds a promise as a potential therapeutic agent for treating osteoporosis and maintaining bone health.

Purpose: Fibrodysplasia ossificans progressiva (FOP) is an ultra-rare, severely disabling genetic disorder characterized by progressive heterotopic ossification (HO). The phase III MOVE trial (NCT03312634) evaluated the efficacy and safety of the selective retinoic acid receptor-? agonist, palovarotene, in reducing new HO in FOP.1 Using a weighted linear mixed effects (wLME) model, post hoc 18-month interim analyses of MOVE showed that palovarotene reduced annualized new HO volume by 54% compared with patients untreated beyond standard of care from an FOP natural history study (NHS; NCT02322255).1 Palovarotene was generally well tolerated and adverse events were consistent with other systemic retinoids; however, there was a high risk of premature physeal closure in pediatric patients.1 Here, sensitivity analyses are presented to assess the robustness of the 18-month efficacy results previously reported from MOVE. Methods: Mean annualized HO volume assessed by low-dose whole-body computed tomography (WBCT) was compared for palovarotene-treated (MOVE) and untreated (NHS) patients. Sensitivity analyses performed on the wLME model were: inclusion of additional covariates and propensity score quartile as a covariate, extreme annualized new HO volumes of >100.0×103 mm3 set to 100.0×103 mm3, analysis of patients who transitioned from the NHS to MOVE, and propensity score matching and weighting analyses to adjust for baseline differences. A prespecified analysis was also conducted using Generalized Estimating Equations (GEE) modelling without weights. Results: Sensitivity analyses of the wLME model are presented (Table); results showed consistent reductions in annualized new HO volume with palovarotene treatment. Similarly, GEE modelling without weights showed that fitted mean annualized new HO volume was nominally significantly lower, by 54%, in palovarotene-treated (9.4×103 mm3) compared with untreated patients (20.3×103 mm3; nominal p=0.0106). Conclusion: With palovarotene treatment, post hoc sensitivity analyses of MOVE consistently demonstrated reductions in annualized new HO volume. The analyses support previous post hoc findings on the use of palovarotene for reducing new HO, however, the risk-benefit profile of palovarotene treatment should be reviewed on an individual basis. Burden of Fractures for Individuals Living with Osteogenesis Imperfecta: Integrating Real-world Claims Data in the United States and Caregiver Panel Interviews *Heather Byers[3], Erru Yang[3], Jenny McCue[3], Yun Guo[2], Stanley Krolczyk[3]. [3]Ultragenyx, United States. [2]Tianjin Happy Life Technology Co., Ltd, China. [3]Ultragenyx,

Purpose: Osteogenesis imperfecta (OI) is a genetic disease characterized by bone fragility and recurrent fractures, characteristically of the long bones, vertebra, and ribs. However, fracture data by body site are limited. This study aims to quantitively and qualitatively better understand fracture burden among individuals with OI.Methods: For quantitative assessment, the IQVIA PharMetrics® Plus commercial database was searched between January 2017-February 2020 for individuals in 3 cohorts: 1) confirmed OI (>=2 ICD-10-CM Diagnosis Codes Q78.0 thirty days apart), 2) X-linked hypophosphatemia (XLH, ICD-10-CM E83.31), and 3) the general population without OI or XLH. All selected individuals required >=12 months of continuous enrollment. Fractures were identified via ICD-10 diagnosis codes and reported by body sites and age groups. For qualitative assessment, insights were gathered from 23 caregivers of individuals with OI through interviews (n=13) and virtual listening sessions (n=10).Results: Diagnosed fractures at any site occurred in 50% (967/1,949), 15% (817/5,281), and 6% (165,367/3,000,631) of individuals with OI, XLH and the general population, respectively. Age of greatest fracture incidence was 65 years for comparators (XLH: 27%, general: 11%). Among individuals with OI, the most common fracture sites were tibia/fibula (17%), radius/ulna (15%), and vertebrae (13%). Finger and toe fractures occurred in 7% and 8% of individuals with OI, respectively, versus <1% of comparators, and were highest in children aged 5-12 (13%-21%). Interviewed caregivers reported finger and toe fractures occur frequently and are commonly self-splinted at home without seeking medical care. Caregivers also stated that children often delay reporting fractures or pain to avoid missing out on activities.Conclusions: Individuals living with OI, especially children, have a high fracture burden that significantly impacts quality of life. Long bone fractures, including long bones of fingers and toes, occur notably more frequently in OI, even compared to patients with other metabolic bone diseases. Despite this significantly higher incidence of finger and toe fractures seen in subjects with OI, caregivers report they are often underreported within the medical record and contribute to high disease burden.

Purpose: Fibrodysplasia ossificans progressiva (FOP) is an ultra-rare genetic disorder characterized by progressive heterotopic ossification (HO). The phase III MOVE trial (NCT03312634) evaluated palovarotene, a selective retinoic acid receptor-? agonist, in FOP. Post hoc 18-month interim analyses showed palovarotene reduced new HO compared with patients untreated beyond standard of care from an FOP natural history study (NHS; NCT02322255).1 Palovarotene was generally well tolerated with adverse events consistent with other systemic retinoids, but there was a high risk of premature physeal closure in pediatric patients.1 Here, long-term (48 month) efficacy of palovarotene in patients who paused and restarted or stopped treatment in MOVE, due to a partial clinical hold in patients <14 years or dosing interruptions in patients >=14 years, was evaluated. Methods: Mean annualized HO volume changes assessed by low-dose whole-body computed tomography (WBCT) were evaluated to trial completion. Analyses were performed for the MOVE intent-to-treat (ITT) period for: (i) all patients regardless of treatment status (compared with untreated patients from an FOP NHS), (ii) patients who paused and restarted treatment with data in pre-pause, interruption, and post-restart periods (>=2 WBCT scans post-restart), and (iii) patients who paused and stopped treatment. Results: In the ITT period, patients received palovarotene for a mean (standard deviation) of 25.4 (12.5) months and were off treatment for 13.1 (9.3) months. For all patients and for patients who paused and restarted treatment in the ITT period, HO volumes were lower when patients received palovarotene (Table). When patients paused and stopped treatment (n=16), mean annualized new HO volume was 84.9% lower when patients received palovarotene (2.3×103 mm3; mean follow-up: 12.6 months) compared with when they did not (15.6×103 mm3; mean follow-up: 15.7 months). When patients stopped treatment, annualized new HO did not exceed that in untreated patients from the NHS, suggesting no treatment rebound or withdrawal effect. Conclusion: Long-term data from MOVE consistently showed lower annualized new HO volume when patients were treated with palovarotene versus when they were not. The results support previous post hoc findings on the use of palovarotene for reducing new HO. However, the risk-benefit profile of palovarotene should be reviewed on an individual basis. Reference 1. Pignolo RJ. J Bone Miner Res 2023;38:381-394

Table: Analyses of annualized new HO volume from baseline to last visit in the ITT period for all patients and for patients who paused and restarted treatment with data in each period.

MOVE ITT period, all patients[a]			
Treatment (study)	Palovarotene (MOVE) N=97		Untreated (NHS) N=101
Annualized new HO volume (×10³ mm³), wLME LSmean (SEM)	11.2 (3.3)		20.9 (3.7)
wLME reduction in new HO, %	46.4		
wLME estimate (95% CI) (×10³ mm³), p value	-9.7 (-19.8, 0.4), p=0.0585		
MOVE ITT period, only patients with data in all periods[a]			
Time period	Pre-pause N=17	Interruption N=17	Post-restart[b] N=17
Mean duration (months)	20.9	6.8	22.1
Annualized new HO volume (×10³ mm³), mean (SEM)	5.0 (3.5)	29.8 (12.9)	7.7 (5.0)

[a]Baseline total HO, baseline age, sex, baseline months since last flare-up, and baseline CAJIS were included as covariates. [b]Fewer patients paused and restarted palovarotene treatment due to missed WBCT scans and enrolment loss. CAJIS: cumulative analogue joint involvement scale; CI: confidence interval; HO: heterotopic ossification; ITT: intent-to-treat; LSmean: least squares mean; NHS: natural history study; SEM: standard error of the mean; WBCT: whole-body computed tomography; wLME: weighted linear mixed-effect.

Evaluating Setrusumab for the Treatment of Osteogenesis Imperfecta: Phase 2 Data from the Phase 2/3 ORBIT Study *E. Michael Lewiecki[1], Thomas Carpenter[2], Maegen Wallace[3], Peter Smith[4], Erik Imel[5], Hui Wang[6], Heather Byers[8], Stanley Krolczyk[8], Gary Gottesman[9]. [1]University of New Mexico Health Sciences Center, United States. [2]Yale University School of Medicine, United States. [3]University of Nebraska Medical Center, . [4]Shriner's Hospitals for Children, United States. [5]Indiana University School of Medicine, United States. [6]Ultragenyx Pharmaceutical Inc., United States. [8]Ultragenyx, United States. [8]Ultragenyx, . [9]Washington University School of Medicine in St. Louis, United States

Osteogenesis imperfecta (OI) is a rare genetic disorder characterized by bone fragility and low bone mass with no universally-accepted treatment. Setrusumab is a fully-human anti-sclerostin monoclonal antibody that improved bone mineral density (BMD), bone strength, and bone turnover markers in adults with OI (ASTEROID study). The safety and efficacy of setrusumab are further explored in pediatric and young adult cohorts in the Phase 2/3 ORBIT study (NCT05125809).The Phase 2 portion aims to select a setrusumab dosing strategy for patients with OI based on PK/PD, safety, and lumbar spine dual-energy x-ray absorptiometry (DXA) BMD. Subjects with OI Types I, III, or IV, ages 5 to <26 years, were randomized 1:1 to receive 20 or 40 mg/kg setrusumab intravenously monthly. Up to six-month trial data are presented.Twenty-four subjects (50% female, 75% <18 years of age) with OI Type I (n=17/24, 71%) or III/IV (n=7/24, 29%) were enrolled and randomized to receive 20 mg/kg (n=14/24) or 40 mg/kg (n=10/24) setrusumab.Subjects in the 20 mg/kg setrusumab group had a mean (SD) baseline-corrected area under the effect curve (AUEC) for serum P1NP of 4152.7 µg/L*day (4406.5) over the first month of treatment, compared with 5256.4 µg/L*day (5521.3) in the 40 mg/kg group.Mean (SD) change from baseline in lumbar spine BMD in the 20 mg/kg group was 10.5% (6.3%) and 10.2% (3.1%) at M3 and M6, respectively, compared with 10.1% (8.0%) and 21.6% (24.8%) in the 40 mg/kg group (all p<0.05 vs baseline). Mean (SD) baseline BMD Z-score in the 20 mg/kg group of 2.1 (2.8) improved by 0.7 (0.4) at M3 and 0.8 (0.3) at M6, while the 40 mg/kg group improved from 1.1 (1.1) at baseline by 0.6 (0.6) and 1.1 (1.6) at M3 and M6, respectively.Fractures occurred on study and were seen in both groups; additional analyses will investigate incidence over time.Setrusumab treatment in the pediatric cohort resulted in no unexpected adverse events and no significant differences in efficacy across dosing groups or age ranges. Treatment-related adverse events included infusion-related reaction (6/24, 25.0%), and infusion site pain, bone pain, upper respiratory tract infection, and headache (each 1/24, 4.2%).In the Phase 2 portion of ORBIT, significant increases from baseline were observed in P1NP after 1 month of setrusumab treatment, corresponding to BMD improvements at M3 and M6 at both 20 and 40 mg/kg doses. No marked differences in P1NP or BMD were apparent between dosage groups by 6 months.

Background: Hemophilia is a rare inherited X-linked disorder caused by a deficiency of certain blood clotting proteins such as Factor VIII. There are two forms of hemophilia: the more common hemophilia A, which results from a deficiency of coagulation factor VIII, and the less frequent hemophilia B, caused by a deficiency of coagulation factor IX. Coagulation factor deficiency causes both spontaneous and post-traumatic bleeding events. Hemophilia is associated with reduced bone mass and mineral density (BMD) both in adults and children mainly related to impaired mobility and vitamin D deficiency. Due to the rarity of the disease and the heterogeneity among the studies, pathogenesis of bone loss is still under investigation.Objectives: To dissect the mechanism of bone loss in Hemophilia A, we studied the effects on coagulation factors on bone cells and we characterized the osteoclastogenic potential of osteoclast precursors of patients.Patients/Methods: We treated Healthy Donors PBMC (HD-PBMC) and osteoblasts with FVIII, von Willerbrand Factor (VWF), FVIII/VWF, FXa and Thrombin. Osteoclastogenesis and FACS analyses of osteoclast precursors isolated from patients were performed; Alkaline Phosphatase (ALP) staining revealed the effects of coagulation factors on osteoblasts.Results and Conclusions: We showed a significant reduction of mature osteoclasts after treatment of HD-PBMC with FVIII, von Willerbrand Factor (VWF), FVIII/VWF, FXa and thrombin.Interestingly, PBMC isolated from hemophilic patients showed increased osteoclastogenic potential due to alteration of osteoclast precursor population. Moreover, transcriptional analysis revealed increased RANK, TRAF6 (TNF receptor-associated factor 6), CTSK (Cathepsin K) and TCIRG1 (T Cell Immune Regulator 1) genes expression in adult patient's osteoclasts compared to controls. FVIII and VWF treatments led also to a statistically significant reduction of ALP positivity in control osteoblasts. All these data suggest that bone loss observed in patients could be related to altered bone remodelling due to a direct effect of coagulation factors on bone cells. These results may have important implications in the clinical management of hemophilic patients to prevent bleeding as well as preserve the bone health.

Bone Mineralization in 8 adults with Osteogenesis Imperfecta: a bone biopsy study *Delphine Farlay[1], Guilllaume Chevrel[2], Pascale Chavassieux[3], Roland Chapurlat[4]. [1]INSERM, UMR1033; Universite De Lyon, France. [2]Univ. Lyon, INSERM, UMR 1033, F-69008 Lyon, France. [3]INSERM UMR1033, Universite De Lyon, France. [4]INSERM UMR 1033, France

Osteogenesis imperfecta (OI) is an inherited disorder characterized by bone brittleness associated with low bone mass. In adult patients with OI, the incidence of fractures that decreases after puberty remains low until menopause in women and the age of 70 in men. Alendronate is a potent bisphosphonate able to increase BMD of the spine and hip and decrease by ?50% the incidence of vertebral fractures in postmenopausal women with osteoporosis (PMOP). In a clinical trial (ALOIA) that included 64 patients1 receiving either placebo (PBO; calcium + vitamin D) or 10 mg/day of alendronate (ALN) for 3 years, BMD at hip and spine was significantly increased, but no difference in the fracture incidence rate was observed between the 2 groups. The aim of this analysis was to determine the degree of mineralization (DMB) of bone in 8 adults (7 men, 1 woman) with Type I OI (quantitative mutations) from ALOIA study (PBO: n:5, aged 43+14 yrs; ALN: n:3, aged 44+4 yrs) who underwent transiliac bone biopsies after 3 yrs of treatment. Bone histomorphometry was performed and was available in 5 patients. DMB and heterogeneity index (HI) of mineralization were measured by X-ray microradiography. Cortical (Ct) and cancellous (Cn) bone were analyzed. Owing to the small number of samples, no statistical analysis was performed and the data were only descriptive. DMB was elevated in PBO and ALN patients in both Ct (PBO: 1.171+0.032; ALN:1.184+0.043 g/cm3), and Cn (PBO: 1.076+0.035; ALN: 1.092+0.065 g/cm3) bone. HI was low in PBO and ALN patients in both Ct (PBO: 0.108+ 0.013; ALN: 0.110+0.028 g/cm3) and Cn (PBO: 0.159+ 0.035; ALN: 0.125+0.035 g/cm3) bone. By comparison, in PMOP women treated for 8 years with BPs2, DMB was 1.053+0.027 in Ct and 1.014+0.026 g/cm3 in Cn bone, and HI was 0.143+0.022 in Ct and 0.153+0.024 g/cm3 in Cn bone. Histomorphometric analysis showed a great variability of bone turnover among these OI patients, with a trend towards an increase in MAR (0.97+ 0.11 µm/d in PBO, n=3; 0.93 µm/d, n=1 in ALN) compared to normal population (0.59+0.09)3. In conclusion, compared to long-term treated bisphosphonate patients, OI is characterized by a high DMB and a low HI, that may be associated with increased bone brittleness in OI patients. No difference in DMB or HI between ALN and PBO groups was observed, likely due to the small sample size. 1 Chevrel et al. J Bone Miner Res, 21, 2006 2 Farlay et al. Altered Collagen Secretion and Organization Contributes to the Bone Fragility in a Copb2+/- Mouse Model *Ronit Marom[1], AVA BERRIER[2], Megan Washington[3], I-Wen Song[3], Vittoria Rossi[3], Yuqing Chen[3], Xiaohui Li[3], Brian C. Dawson[3], Joseph M. Sliepka[4], D. Nicole Meyers[5], Cole Kuzawa[5], Lindsay C. Burrage[3], Catherine Ambrose[5], Brendan Lee[3]. [1]BAYLOR COLLEGE OF MEDICINE, United States. [2], . [3]Baylor College of Medicine, United States. [4]University of Washington, United States. [5]University of Texas Health Science Center at Houston, United States

Pathogenic variants in genes encoding subunits of coat protein complexes (coatomers), Golgi proteins, and motor proteins within the secretory pathway are associated with diverse phenotypes, including low bone mineral density and bone fragility, due to a defect in the sorting and transport of proteins between subcellular organelles. We had previously reported heterozygous, loss-of-function variants in COPB2, encoding a subunit of the coatomer complex I (COPI), in individuals presenting with a clinical spectrum of osteopenia, recurrent fractures, and intellectual and developmental disabilities.To better understand how COPB2 haploinsufficiency affects skeletal development, a phenotypic analysis was performed in Copb2+/- mice. Analysis of bone mass using micro-CT imaging showed a 15-20% reduction in spine bone volume/total volume (BV/TV) in 2-month-old Copb2+/- mice, compared to control wild-type littermates. Additionally, in females, the spinal trabecular number, trabecular thickness, and femur cortical thickness were significantly reduced. Polarized light microscopy imaging of Copb2+/- mouse vertebrae stained with picrosirius red showed disorganization of the collagenous matrix, as evidenced by increased yellow-green birefringence. Altered distribution of collagen fibers can affect the mechanical properties of bone and further the underlying collagen trafficking and synthetic defect. Consistent with this, the biomechanical testing of Copb2+/- mice femurs by 3-point bending demonstrated decreased ultimate load and stiffness, indicating reduced bone strength. To correlate these findings with delayed trafficking in vitro, collagen secretion was studied using pulse-chase assay in siRNA-treated cells. An 80% reduction in Copb2 expression was associated with a dramatic decrease in labeled procollagen secretion to the media.In conclusion, our data suggest that altered secretion and distribution of collagen likely contributes to the osteoporosis and bone fragility in patients with COPB2 haploinsufficiency. Understanding the mechanism of COPB2-related disorder will provide insights about procollagen secretion in bone cells, and about the role of intracellular protein trafficking in skeletal homeostasis.

AAV-mediated gene editing of type 1 collagen mutation for Osteogenesis Imperfecta *Yeon-Suk Yang[1], Tadatoshi Sato[1], Sachin Chaugule[1], Zhihao Chen[1], Agustina Rodriguez[1], Hong Ma[1], Jun Xie[1], Guangping Gao[1], Jae-Hyuck Shim[1]. [1]UMass Chan Medical School, United States

Background:Osteogenesis Imperfecta (OI) is the most common rare skeletal disease characterized by bone fragility. The incidence is approximately 1 in 25,000-50,000 in the US. Up to 85% of OI patients have autosomal dominant mutations in either the COL1A1 or COL1A2 gene. The treatments of OI are improving bone strength, reducing fracture risk and pain, and preventing long-term complications. However, treatment options show limited success because they cannot alter the causes of collagen mutations or effectively deliver the drugs to the bone tissue.Methods/results:To develop novel therapeutics to correct collagen mutations in OI, we recently developed a bone-tropic AAV capsid by grafting bone-homing peptides ((AspSerSer)6, DSS) to the VP2 capsid protein (rAAV9.DSS) and confirmed that rAAV9.DSS was highly effective for the transduction of bone-forming osteoblasts (OB) in vitro and in vivo. We also used OIM mice harboring the deletion of a single-nucleotide (G) at 3983 in the Col1a2 gene as a mouse model of the dominant form of human OI (type 3). As a result, OIM mice displayed smaller body sizes, multiple non-union bone fractures, and pelvic bone deformity. µCT analysis demonstrated a significant decrease in trabecular bone mass in the long bones of these mice. CRISPR-Cas9 is one of the most powerful gene editing tools for skeletal rare diseases. We examined CRISPR-Cas9-mediated editing efficiency of the Col1a2 gene in immortalized OIM OB line. The gene-editing efficiency in these cells was substantially increased when CRISPR/Cas9 was coupled with a donor AAV vector containing a promoterless partial mouse Col1a2 complementary DNA sequence (GeneRide designed the optimized Condons for avoiding OIM mutation gRNA targeting, Figure 1) confirmed by NGS (next generation sequencing) analysis. This approach effectively reversed

the dysregulation of osteogenic differentiation by a Col1a2 mutation in vitro. Furthermore, systemic administration of dual AAV vectors lowered bone matrix turnover rates by reducing osteoblast and osteoclast development while improving the cellular network of mechano-sensing osteocytes embedded in the bone matrix. This strategy significantly improved bone architecture/mass/mineralization, skeletal deformities, grip strength, and spontaneous fractures.Conclusion:Taken together, these findings demonstrate that AAV-mediated gene editing effectively corrects a collagen mutation in OI osteoblasts and reverses skeletal phenotypes in OIM mice.

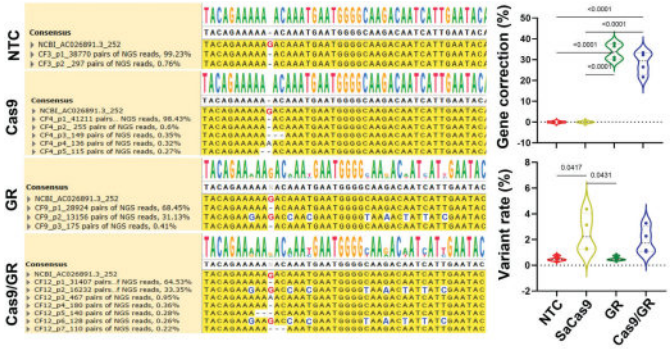

Figure 1. AAV-mediated Col1α2 gene correction in OIM osteoblasts. Immortalized OIM$^{m/m}$ osteoblasts were treated with AAV vectors, and two days later, genomic DNA was extracted and subjected to NGS analysis (n = 4). GR or Cas9/GR restored the missing "G" (red) in the Col1α2 gene, while eight nucleotides (blue) were adapted from GR. Percentage of sequence reads of Col1α2 gene correction (top right) or variants (bottom right) are displayed.

Challenges of musculoskeletal multimorbidities in sub-Saharan Africa: findings from the Fractures-E3 and MUFASSA studies *Kate Ward[1,] Lisa Micklesfield[2,] Lucy Gates[3,] Tedios Manyanga[4,] Momodou Jallow[5,] Bilkish Cassim[6,] Yoliswa Madela[7,] Anya Burton[8,] Hannah Wilson[9,] Rashida Ferrand[10,] Celia Gregson[11,] [1]MRC Lifecourse Epidemiology Centre, University of Southampton, United Kingdom, [2]SAMRC/Wits Developmental Pathways for Health Research Unit, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, South Africa, [3]MRC LIfecourse Epidemiology Centre, University of Southampton, United Kingdom, [4]The Health Research Unit Zimbabwe, , Zimbabwe, [5]MRC Unit The Gambia at LSHTM, Gambia, [6]Department of Geriatrics School of Clinical Medicine, University of Kwa-Zulu Natal , South Africa, [7]Department of Geriatrics School of Clinical Medicine, University of Kwa-Zulu Natal, South Africa, [8]6 Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, United Kingdom, [9]Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, United Kingdom, [10]The Health Research Unit Zimbabwe, LSHTM, Zimbabwe, [11]University of Bristol, United Kingdom

Age-related diseases of bone (osteoporosis) and of muscle (sarcopenia) impact functional ability, through falls and fragility fractures. Currently, there are few data across sub-Saharan Africa quantifying prevalence of musculoskeletal disorders in ageing populations; such data are necessary to plan future healthcare services. The objective is to determine sarcopenia and fall prevalence in women and men in South Africa (SA), The Gambia (Gam) and Zimbabwe (Zim), compare by sex and explore factors associated with outcomes. By household sampling, a community-based sex- and age-stratified sample of urban-dwelling men and women aged 40 years and older were recruited1. Participants had hand grip strength, gait speed, sit-to-stand time and balance measured as part of the Short Physical Performance Battery (SPPB) and self-reported falls in the last year were recorded. Sarcopenia was defined as gait speed <1.0metres/second and grip strength <35.5kg in men and <20kg in women2. Differences between groups were tested using T-tests, Mann-Whitney-U and Chi-squared tests.Sarcopenia was more prevalent in men than women (Table 1). Low gait speed was seen in >75% men and >85% women in all countries, with low grip strength much less prevalent with men ranging from 22-34% and women 4.7-12.2% (sex-differences p<0.001). Those with sarcopenia were older (especially in Zim) with lower BMI. Overall, >=1 fall was reported by 155/885 (18%) in Zim, 174/673 (28.5%) in Gam, & 131/816 (17%) in SA; sarcopenia was associated with falling in Zim only (p=0.05), potentially a function of sample size and age of cohort; only 23.9% of fallers were classified as sarcopenic.Sarcopenia prevalence was low in women which contrasts with other populations. In men prevalence was higher than in the US & Europe1. Self-reported fall prevalence across men and women were similar to elsewhere. There is a need to validate context-specific thresholds for poor functional ability and sarcopenia. The Fractures-E31 and MUFASSA studies are generating important evidence needed to inform future health planning for older people, particularly regarding challenges to functional ability, and healthy ageing.References: 1 Burton A, Drew S, Cassim B et al. A Skeletal Muscle-specific Aptamer Facilitates Muscle-targeted Drug Delivery In Vivo *Zongkang Zhang[2,] Shanshan Yao[2,] Hewen Jiang[2,] Huan Xiao[2,] Baoting Zhang[2,] [2]The Chinese University of Hong Kong, , [2]The Chinese University of Hong Kong, Hong Kong

The skeletal muscular disorders, such as sarcopenia and Duchenne muscular dystrophy, are related to serious health consequences. However, one major bottleneck of current pharmacological therapies for skeletal muscle disorders is lack of muscle cell selectivity, leading to low efficacy and off-target side effects when administered systemically. Nucleic acid aptamers are promising escort molecules for drug delivery systems. Utilizing cell-based systematic evolution of ligands by exponential enrichment (cell-SELEX) technology, we identified one aptamer SkMApt1 showed higher affinity and selectivity to skeletal muscle than scramble aptamer both in vitro and in vivo. We previously reported microRNA-487b (miR-487b) is an anabolic suppressor in skeletal muscle during sarcopenia development. To further evaluate the efficacy of SkMApt1-facilitated skeletal muscle-targeted drug delivery, we prepared SkMApt1-functionalized lipid nanoparticles (LNPs) encapsulating antagomiR-487b (Apt1-LNPs-antimiR). The fluorescence labeled antimiR distribution in different tissues were evaluated by ex vivo florescence imaging in mice. The fluorescence signal intensity of Apt1-LNPs-antimiR in skeletal muscle was significantly higher, whereas the fluorescence signal intensities in liver and kidney were significantly lower when compared to scramble aptamer control. Moreover, eight periodic intravenous administrations (once per week) of Apt1-LNPs-antimiR promoted the muscle mass, muscle fiber CSA and muscle strength of muscle-specific miR-487b knockin mice. Apt1-LNPs-antimiR treatment inhibited miR-487b level and elevated Wnt5a protein level in skeletal muscle of muscle-specific miR-487b knockin mice, while blank or scramble aptamer conjugated LNPs-antimiR treatment failed to achieve the above results. Taken together, the above findings suggested that SkMApt1 could be a potential skeletal muscle-targeted moiety to facilitate muscle-targeted drug delivery. Acknowledgments: This study was supported by the Hong Kong General Research Fund (14103420, 14109721, 14103121), and Hong Kong CUHK Direct Grant (4054714).

A Randomized Controlled Trial to Investigate the Effect of Luseogliflozin on Bone Microarchitecture in Elderly Patients with Type 2 Diabetes Using High-Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) *Riyoko Shigeno[1,] Ichiro Horie[1,] Norio Abiru[1,] Ryuji Niimi[2,] Ko Chiba[2,] Makoto Osaki[3,] Atsushi Kawakami[1,] [1]Department of Endocrinology and Metabolism, Nagasaki University Hospital, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Japan, [3]Nagasaki University, Japan

Aim: Patients with type 2 diabetes (T2D) have an increased risk of bone fractures despite having increased bone mineral density (BMD). In the CANVAS program, an SGLT2 inhibitor canagliflozin was related to an increased fracture risk as early as 12 weeks after initiating the drug in patients with T2D, but other SGLT2 inhibitors did not affect the fracture risk in clinical trials. It remains unclear whether SGLT2 inhibitors lead deterioration of bone quality. We prospectively studied the effect of an SGLT2 inhibitor luseogliflozin on bone microarchitecture and strength in patients with T2D using HR-pQCT.Methods: This is a randomized, open-label, active-controlled trial for elderly (>=60 years) Japanese patients with T2D. We enrolled patients uncontrolled with HbA1c levels of 7.0-8.9 % by the treatment with diet alone or with mono- or combination therapy with metformin (<=?1000?mg/day), ?-glucosidase inhibitor and dipeptidyl peptidase-4 inhibitor. Patients were randomized to either the luseogliflozin (Lusefi) group (added luseogliflozin 2.5 mg) or the control (CTRL)

group (added metformin 500 mg) and have treated for 48 weeks. Bone microarchitecture was evaluated using HR-pQCT (Xtreme CT II, Scanco Medical, Switzerland) in addition to BMD by dual-energy X-ray absorptiometry (DXA) before and 48 weeks after treatment. The primary outcome was 48-weeks change in the predictive bone strength (failure load, kN) determined HR-pQCT in Lusefi group compared to CTRL group using a linear regression model.Result: Of the 22 patients (Female,32%), 20 patients (9 in Lusefi, 11 in CTRL groups) completed the study. There were no significant differences in the changes in BMD measured by DXA before and after treatment in the two groups. As the primary outcome determined by HR-pQCT, the 48-weeks changes in the estimated failure load showed no significant decrease in Lusefi group compared to CTRL group using a linear regression model.Result: Of the 22 patients (Female,32%), 20 patients (9 in Lusefi, 11 in CTRL groups) completed the study. There were no significant differences in the changes in BMD measured by DXA before and after treatment in the two groups. As the primary outcome determined by HR-pQCT, the 48-weeks changes in the estimated failure load showed no significant decrease in Lusefi group compared to CTRL group (?, 35; 95%CI, -215 to 284 at radius, and ?, -147; 95%CI, -330 to 36 at tibia). In the secondary outcomes, cortical porosity (%) in radius tended to decrease after treatment in Lusefi group compared to CTRL group (?, -0.061; 95%CI, -0.12 to 0.0027; p=0.059). The changes in the other HR-pQCT parameters from baseline to 48 weeks showed no significant differences between the two groups.Conclusion: We observed no negative effect of luseogliflozin treatment on bone microarchitecture and bone strength evaluated by HR-pQCT compared to metformin treatment in short standing investigation.

HR-pQCT and Risk Factors in Type 1 Diabetes *Naina Sinha Gregory[1], Andrew J. Burghardt[2], Jye-Yu C. Backlund[3], Mishaela R. Rubin[4], Ionut Bebu[3], Barbara H. Braffett[3], David J. Kenny[3], Thomas M. Link[2], Galateia J. Kazakia[2], Annette Barnie[5], John M. Lachin[3], Rose Gubitosi-Klug[6], Ian H. de Boer[7], Ann V. Schwartz[2]. [1]Weill Cornell Medicine, [2]University of California San Francisco, United States, [3]The George Washington University, United States, [4]Columbia University, United States, [5]University of Toronto, Canada, [6]Case Western Reserve University, United States, [7]University of Washington, United States

Type 1 diabetes is associated with a nearly five-fold greater risk of hip fracture that is not accounted for by the modest decrease in BMD. This discrepancy points to other factors that impact bone strength including bone geometry and microarchitecture. We set out to determine whether type 1 diabetes and its complications are associated with bone geometry, microarchitecture, and strength. This was a cross-sectional study embedded in a long-term observational study. High-resolution peripheral quantitative computed tomography (HR-pQCT) scans of the distal radius and distal and diaphyseal tibia were performed in a subset of 183 participants from the Diabetes Control and Complications Trial/Epidemiology of Diabetes Interventions and Complications (DCCT/EDIC), a long-term follow-up of participants with type 1 diabetes and 94 controls without diabetes. HbA1c, advanced glycation end products (AGEs), and diabetes-related complications were assessed in EDIC participants with >30 years of follow-up. Compared to controls (60 +/- 8 years old and 65% female) , EDIC participants (60 +/- 7 years old, duration of type 1 diabetes 38 +/- 5 years, and 51% female) had lower total bone mineral density (BMD) at the distal radius (-7.9%, 95%CI:(-15.2%,-0.6%), p=0.030) and distal tibia (-11.3%, 95%CI:(-18.5%,-4.2%), p=0.001); larger total cross-sectional area at all sites (distal radius +4.7%, 95%CI:(+0.5%,+8.8%), p=0.030; distal tibia +5.9%, 95%CI:(+2.1%,+9.8%), p=0.003; diaphyseal tibia +3.4%, 95%CI (+0.8%,+6.1%), p=0.011); and poorer radius trabecular and cortical microarchitecture. Estimated failure load was similar between two groups. Among the EDIC cohort, higher HbA1c and AGE and macroalbuminuria were associated with lower total BMD. Macroalbuminuria was associated with larger cross-sectional area and lower cortical thickness at the distal radius. Higher HbA1c and AGE, lower glomerular filtration rate, peripheral neuropathy and retinopathy were associated with deficits in trabecular microarchitecture. These results revealed that type 1 diabetes is associated with lower BMD, larger bone area and poorer trabecular microarchitecture. In those with type 1 diabetes, suboptimal glycemic control, AGE accumulation and microvascular complications, particularly reduced renal function, are associated with deficits in bone microarchitecture and lower BMD.

The importance of kynurenine monooxygenase, KMO in regulation of kynurenine-induced bone loss with age *Dmitry Kondrikov[1], Galina Kondrikova[2], Xing-ming Shi[3], Mark Hamrick[4], Carlos Isales[5], Sadanand Fulzele[6], Meghan McGee-Lawrence[4], William Hill[7]. [1]Department of Pathology and Laboratory Medicine, Medical University of South Carolina, United States, [2]Department of Pathology and Laboratory Medicine, Medical University of South Carolina, United States, [3]Neuroscience and Regenerative Medicine, Augusta University, United States, [4]Cellular Biology and Anatomy, Medical College of Georgia, Augusta University, United States, [5]Augusta University, United States, [6]Division of Endocrinology, Diabetes and Metabolism, Medical College of Georgia, Augusta University, United States, [7]Medical University of South Carolina, United States

Kynurenine pathway metabolites are emerging as important factors in the pathophysiology of aging-related bone loss. Our group has previously shown that the essential amino acid tryptophan is metabolized by IDO-1 in the periphery to generate kynurenine (KYN), and that KYN can act though the aryl hydrocarbon (AhR) receptor signaling pathway to inhibit osteogenesis in bone marrow MSCs via epigenetic regulation of osteogenic genes, while also upregulating osteoclastogenic transcription factors and genes driving osteoclast activity. Further, we recently showed that KYN, acting via KLF6 through the AhR non-canonical XRE pathway, induces senescence and suppresses autophagy in human BMSCs. Also, we demonstrated that KYN pathway metabolites downstream from KYN, 3-hydroxykynurenine (3-HK) and quinolinic acid (QA) act via the AhR signaling pathway also inhibit autophagy, induce Senescence Associated Secretory Phenotype (SASP) molecular expression, and drive senescence in murine and human bone marrow MSCs, similar to KYN.Here, we demonstrate that kynurenine monooxygenase (KMO) plays an important role in kynurenine-induced bone loss. Inhibition of KMO pharmacologically, or by siRNA, prevents KYN-induced senescence, and restores autophagic flux in murine and human BMSCs. KMO inhibition suppresses osteoclast differentiation of human CD14-positive bone marrow and peripheral blood derived macrophages. At the same time, inhibition of KMO promotes osteogenic differentiation of human BMSCs rescuing KYN-induced suppression of osteogenesis. KMO protein levels are higher in osteoblasts and osteocytes in the femurs of aged mice compared to young mice, as well as in mice treated with KYN. KMO gene expression is also elevated with age or KYN treatment in human BMSCs. This suggests KMO levels are potentially increased in response to aging-related factors, including increases in its substrate KYN, thus elevating sub-KMO metabolite levels and possible canonical and non-canonical AhR XRE signaling and gene expression. This makes KMO an attractive target for more precise control of kynurenine pathway effects. Blocking KYN downstream metabolite formation, rather than KYN itself by inhibiting KMO, presents a novel therapeutic target linked to the regulation of kynurenine pathway metabolites and their signaling. As such, inhibiting KMO may allow rescue of bone homeostasis and reduction of bone loss in aged patients.

Efficacy of Moderate-Dose Denosumab in Fibrous Dysplasia: Secondary Results from a Phase 2 Clinical Trial *VIVIAN SZYMCZUK, National Institutes of Health ; Ramzy Ahmed, Eastern Virginia Medical School, United States; Ibrahim Elbashir, National Institute of Dental and Craniofacial Research, National Institutes of Health, United States; Alison Boyce, National Institutes of Health

Kynurenine pathway metabolites are emerging as important factors in the pathophysiology of aging-related bone loss. Our group has previously shown that the essential amino acid tryptophan is metabolized by IDO-1 in the periphery to generate kynurenine (KYN), and that KYN can act though the aryl hydrocarbon (AhR) receptor signaling pathway to inhibit osteogenesis in bone marrow MSCs via epigenetic regulation of osteogenic genes, while also upregulating osteoclastogenic transcription factors and genes driving osteoclast activity. Further, we recently showed that KYN, acting via KLF6 through the AhR non-canonical XRE pathway, induces senescence and suppresses autophagy in human BMSCs. Also, we demonstrated that KYN pathway metabolites downstream from KYN, 3-hydroxykynurenine (3-HK) and quinolinic acid (QA) act via the AhR signaling pathway also inhibit autophagy, induce Senescence Associated Secretory Phenotype (SASP) molecular expression, and drive senescence in murine and human bone marrow MSCs, similar to KYN.Here, we demonstrate that kynurenine monooxygenase (KMO) plays an important role in kynurenine-induced bone loss. Inhibition of KMO pharmacologically, or by siRNA, prevents KYN-induced senescence, and restores autophagic flux in murine and human BMSCs. KMO inhibition suppresses osteoclast differentiation of human CD14-positive bone marrow and peripheral blood derived macrophages. At the same time, inhibition of KMO promotes osteogenic differentiation of human BMSCs rescuing KYN-induced suppression of osteogenesis. KMO protein levels are higher in osteoblasts and osteocytes in the femurs of aged mice compared to young mice, as well as in mice treated with KYN. KMO gene expression is also elevated with age or KYN treatment in human BMSCs. This suggests KMO levels are potentially increased in response to aging-related factors, including increases in its substrate KYN, thus elevating sub-KMO metabolite levels and possible canonical and non-canonical AhR XRE signaling and gene expression. This makes KMO an attractive target for more precise control of kynurenine pathway effects. Blocking KYN downstream metabolite formation, rather than KYN itself by inhibiting KMO, presents a novel therapeutic target linked to the regulation of kynurenine pathway metabolites and their signaling. As such, inhibiting KMO may allow rescue of bone homeostasis and reduction of bone loss in aged patients.

Identification of one-carbon metabolism and methionine as regulator of bone loss during fasting *Tânia Amorim[1], William Dion[2], Trishya Pagadala[2], Natalie L David[3], Naveen VG Kumar[2], Tristan Pesaresi[2], Nandini K Doshi[2], Rosemary Andrews[2], Andrey Parkhitko[2], Matthew L Steinhauser[4], Pouneh Fazeli[5]. [1]University of Pittsburgh, , [2]Aging Institute, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, [3]Neuroendocrinology Unit, Division of Endocrinology and Metabolism, University of Pittsburgh School of Medicine, Pittsburgh, PA 2 Aging Institute, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, [4]1 Aging Institute, University of Pittsburgh School of Medicine, Pittsburgh, PA 2 Center for Human Integrative Physiology, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, [5]University of Pittsburgh School of Medicine, United States

In non-human models, fasting has beneficial effects on longevity; however, a potential negative effect of fasting is bone loss. Our aim was to test the effect of a prolonged fast on bone microarchitecture and identify novel metabolic regulators of bone turnover. Bone microarchitecture (HR-pQCT) and bone turnover markers (ELISA) were measured during a 10-day, 0-calorie fast in healthy humans [N=12, median age: 29.3yrs (21.8-48.3), 8 premenopausal females]. After fasting, radial Tb.N and BV/TV significantly decreased (-9.2%+7.9 (mean+SD) and -0.7%+0.7, respectively, $p<0.05$ for both), whereas Tb.Th and Tb.Sp increased (10.3%+8.7 and 11.0%+9.4, respectively, $p<0.05$ for both). After 5 days of fasting, P1NP decreased by 55%, $p<0.05$. Using previously published metabolomics data from this study, one-carbon metabolism was identified as one of the most enriched fasting-dependent pathways. This provided rationale for a new hypothesis - one or more one carbon metabolites regulate bone turnover. We systematically manipulated levels of one-carbon metabolites in cultured osteoblasts and methionine was the only candidate to consistently impact metrics of osteoblast function. Gene transcripts related to bone formation (P1NP, ALPL) and osteoblast function (OCN, OPG, ATF4, RUNX2) were significantly attenuated by excess methionine (100 and 500 µmol; ~2-fold reduction, $p<0.05$), an effect also observed at the protein level (RUNX2 and ATF4 immunoblotting). Given the known link between methionine and histone methylation, we tested if manipulating methionine modulates histone methylation. H3K9me and H3K27me histone marks were augmented in osteoblasts cultured in excess methionine. Consistent with western blot assays, we observed a trend towards increased H3K9me and H3K27me3 at ATF4 and RUNX2 promoters in osteoblasts with methionine excess ($p=0.14$). We then conducted a 5-day murine study with 3 groups: vehicle; methionine excess (60mg/day); and 24h fast. Transcripts for Igf1 and Ocn were decreased in femurs of mice treated with excess methionine vs. controls ($p<0.05$), a pattern seen in fasted mice also. Transcription of Mat1A ($p<0.001$) and Bhmt ($p<0.01$) was also increased in the liver of fasted vs. non-fasted mice, supporting the hypothesis that the methionine pathway is upregulated with fasting. In conclusion, a 10-day fast in humans leads to remodeling of bone microarchitecture. Elevations in circulating methionine with fasting may contribute to fasting-associated bone loss.

Enhanced lipolysis in osteoblast progenitor cells protects from high fat diet-induced bone dysfunction *Ananya Nandy[1], Elizabeth Rendina-Ruedy[2]. [1]Vanderbilt University Medical Centre, , [2]Vanderbilt University Medical Center, United States

Skeletal homeostasis is maintained by a balance between two highly energy consuming processes, bone formation and resorption. As such, formation of new bone is associated with maturation of stromal cells to matrix and mineral secreting osteoblasts, requiring robust amount of cellular energy or adenosine triphosphate (ATP). Therefore, alterations in systemic metabolism can likely directly influence osteoblast function. In this regard, Type 2 diabetes mellitus (T2DM) is a common metabolic disorder that is associated with increased risk of fracture. In other tissues, impaired lipid metabolism is a key feature of T2DM-related pathologies. Therefore, we tested the hypothesis that the reduced bone formation described in diet-induced obese models of T2DM are a function of disrupted lipid metabolism in osteoblasts. Our data confirm that mice fed a high fat diet display reduced bone microarchitecture along with lower bone formation rates. Interestingly, osteoblast isolated and cultured ex vivo from high-fat diet fed mice contain a higher number of lipid droplets along with reduced bioenergetic profile compared to osteoblasts harvested from mice fed a control diet. Further supporting this observation, bone tibia cortex, devoid of marrow elements, had higher lipid content in the form of triacylglycerol (TAGs) in mice fed a high fat diet compared to control-fed mice. As a further proof of principle, we generated a novel murine model to conditionally delete Plin2 in osteoblast-progenitor cells using Prrx1-Cre, Prrx1-Cre.Plin2 mice along with their littermate, wildtype controls. Disruption of Plin2 has previously been reported to enhance lipolysis, and in this capacity, has been demonstrated to protect other tissues from high-fat diet induced lipid dysfunction. Our data demonstrate the Prrx1-Cre. Plin 2 mice are protected from diet-induced obesity related bone impairments as trabecular microarchitecture are similar to that of wildtype controls, along with comparable bone formation rates. In conclusion, our study shows high fat diet leads to perturbation of lipid metabolism in bone causing decreased bone formation which can be reversed by increasing lipolysis in osteoblasts possibly by increasing utilization of fatty acids by these cells.

Stimulation of mitochondria dysfunction in the osteoblast lineage recapitulates part of the effects of aging: evidence from single-cell RNA-seq *Md Mohsin Ali[1], Aaron Warren[1], Ha-Neui Kim[2], Intawat Nookaew[3], Charles O'Brien[4], Maria Jose Almeida[5]. [1]The university of Arkansas for Medical Sciences , United States, [2]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States, [3]University of Arkansas for Medical Sciences, United States, [4]Univ of Arkansas for Medical Sciences, United States, [5]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, United States

Mitochondria dysfunction causes DNA damage, senescence, and loss of proteostasis due, at least in part, to increased production of reactive oxygen species (ROS). All these effects are critical hallmarks of aging, can be interrelated, and have been shown to contribute to skeletal aging. Here, we examined whether mitochondria dysfunction in cells of the osteoblast lineage in vivo is sufficient to promote some of the hallmarks of aging, such as senescence. To this end, we generated mice lacking superoxide dismutase 2 (SOD2) - a critical mitochondrial ROS detoxifying enzyme - in the osteoblast lineage targeted by Osx1-Cre. Specifically, we crossed SOD2-flox and Osx1-Cre mice to generate SOD2?Osx1 and Osx1-Cre control mice. Cultures of bone marrow-derived osteoblastic cells from SOD2?Osx1 mice had lower SOD2 mRNA, increased mitochondrial ROS, and impaired mitochondrial respiration. Osteoblast differentiation markers and mineralization were decreased in cells from SOD2?Osx1 mice. Femoral and vertebral bone mass in female and male SOD2?Osx1 were lower than Osx1-Cre littermates at 3 and 6 months of age. Endosteal mesenchymal cells from long bones were analyzed using single-cell RNA-seq and compared with similar cells obtained from young (6 mo) and old (24 mo) wild-type mice. An initial UMAP plot and cluster analysis, after harmonization of cells from mice of the two experiments, revealed 9 clusters based on expression of cluster-specific markers, including osteocytes, osteoblasts, pre-osteoblasts, osteo-CAR, osteo-X, adipo-CAR, chondrocytes, fibro-1, and fibro-2. Both aging and SOD2 deletion led to a decrease in the proportion of osteoblasts. Overall, the differentially regulated genes with SOD2 deletion and aging exhibited significant overlap, with about 560 genes being commonly up- or down-regulated. Gene Ontology enrichment analysis of differentially expressed genes in osteoblasts revealed that processes related to translation, ribosomes, and ribonucleoproteins were increased with both aging and SOD2 deletion. Senescence, inflammation, and apoptosis processes were increased in osteoblasts with aging but not with SOD2 deletion. On the other hand, processes related to collagen fibril organization and extracellular matrix decreased with age and SOD2 deletion in osteoblasts. These results suggest that mitochondria dysfunction contributes to the decreased osteoblast number and function seen in aged mice, likely via mechanisms independent of cellular senescence.

N7-methylguanosine tRNA modification regulates bone development by controlling amino acid metabolism *Qiwen Li[1], Quan Yuan[2]. [1]State Key Laboratory of Oral Diseases, National Clinical Research Centre for Oral Diseases, West China Hospital of Stomatology, Sichuan University, China, [2]Sichuan University, China

Organ development requires the optimal translation of mRNA to protein that supports stage-specific function. Transfer RNAs (tRNAs) play an essential role in this process. Dysregulation of tRNA was reported in patients with primordial dwarfism, but the underlying mechanism remains unexplored. Here we demonstrate that METTL1/WDR4 complex-mediated N7-methylguanosine (m7G) tRNA modification regulates skeletal development by controlling amino acid metabolism. Deleting m7G catalytic enzyme Mettl1 using Prx1-Cre severely impairs longitudinal bone growth, manifested as reduced proliferation and maturation of chondrocyte, and retarded bone formation and bone mass accrual. Tamoxifen-induced deletion of Mettl1 in chondrocytes using Acan-CreERT2 greatly impairs endochondral bone formation as well. Furthermore, missense mutation of Wdr4 (p.Arg215Leu) reduces METTL1 levels and the bone growth of Wdr4-R215L/R215L mice is greatly inhibited, phenocopying the primordial dwarfism observed in patients. Mechanistically, m7G tRNA reduction and cleavage sequencing (TRAC-seq) reveals that Mettl1 knockout erases m7G modification and reduces abundance of m7G-modified tRNAs, which alters mRNA translation by two approaches. On one hand, Mettl1 knockout evokes translational stress that relays to GCN2, which stalls general translation initiation by phosphorylating eIF2?. Promoting translation initiation by deleting Gcn2, however, aggravates bone defects of Mettl1-deficient mice, indicating a translational protective response to tRNA dysregulation. On the other hand, Mettl1 knockout selectively upregulates translation of mRNAs related to cellular metabolism, in an m7G tRNAs-decoded codon-dependent manner. Mettl1-deficient cells exhibit active cellular respiration despite of incompetent proliferation and chondral-osteo commitment. Ribosome profiling reveals upregulated translation of branched-chain amino acid transaminase 1 (BCAT1), which catalyzes branched-chain amino acid (BCAA) catabolism to support cellular respiration. However, intracellular ?-ketoglutarate (?KG) levels are restricted as BCAT1 transfers ?-amino group from BCAA to ?KG to form glutamate. Supplementation of ?KG ameliorates the skeletal abnormality of Mettl1-deficient mice. Overall, our study unveils a critical role of m7G tRNA modification in bone development by regulat-

ing cellular metabolism, and reveals that stalling of translation initiation as a quality control mechanism in response to tRNA dysregulation.

Osteocyte Connexin Hemichannels and Associated PGE2 Release Regulate Adipogenesis and Body Metabolism *FRANCISCA ACOSTA[4], JINGRUO ZHANG[2], Linda Mota[3], Xuewei Wang[2], Elizabeth Hernandez[3], Manuel Riquelme[4], Eric Brey[3], Jean Jiang[5]. [4]UT Health San Antonio, , [2], , [3]The University of Texas at San Antonio, United States. [4]UT Health San Antonio, United States. [5]University of Texas Health Science Center at San Antonio, United States

Obesity leads to a marked decrease in bone quality & increased fragility, & a reduced quality of life. Bone, & most distinctively osteocytes (Ocy, >90% of bone cells), through involvement in biomechanical, inflammatory, & metabolic signaling, provide a strong deduction for the cross-organ regulation of adipose tissue (AT). Recent work has begun to progress on the intricate link between the release of osteokines, obesity, & metabolic homeostasis. Connexin 43 (Cx43) hemichannels (HCs) are transmembrane proteins richly expressed in Ocy that facilitate extracellular communication. Our lab previously found that Ocy Cx43 HCs are mechanosensitive & exchange multiple small molecules, such as prostaglandin E2 (PGE2), a pleiotropic regulator of bone quality & metabolism. Like during obesity, the loss of Ocy Cx43 HCs compromises bone & biomechanical properties. Here, in vivo studies using transgenic mice models with overexpression of Cx43 dominant negative mutants in Ocy: R76W (inhibited gap junctions, enhanced HCs) & ?130-136 (inhibited HCs & gap junctions), or a monoclonal Cx43(M2) antibody that specifically opens Cx43 HCs, high-fat (+/- 60%) diet, we found that impaired HCs (?130-136) increases harmful AT formation, while enhanced HC activity (R76W/M2) decreases it, ultimately improving whole-body energy expenditure & enhancing systemic metabolic function, all of which is likely inextricably linked to Cx43 HC-mediated PGE2 levels. Specifically, ?130-136 mice showed an ~2.5-fold increase in bone marrow (BM) AT (H&E) & a significant increase in global % Fat (DEXA, H&E, AT weights). Enhancement of HCs (R76W/M2) significantly increased BM & serum PGE2 levels, alongside an enrichment in mice activity, food intake, calorie burnout (Indirect calorimetry), & hindered a rise in glucose, triglycerides, AT hypertrophy/whitening, & liver AT. In vitro, work to further corroborate Cx43 HC-PGE2 mediated AT regulation showed that conditioned media (CM) collected from fluid flow-stimulated Ocy hindered BM & AT-derived stem cell adipogenic differentiation, & this inhibition was ablated with CM from Ocy treated with a HC-blocking antibody. Moreover, the direct addition of PGE2 into culture conditions led to similar inhibition of adipogenesis. These results underline the role of Ocy Cx43 HCs, as key bone & systematic metabolic regulators, possibly mediated through the release of PGE2, & present Ocy Cx43 HCs as potential therapeutic targets for obesity & related metabolic conditions.

Synthetic BMP-2 Analog for Specific Targeting of the Skeletal Stem Cell Niche *Eri Takematsu[1], Liming Zhao[2], Charles Chan[2, 1], United States. [2]Stanford University, United States

Age-related skeletal failures, such as osteoarthritis (OA), causes significant morbidity and affect 350 million people worldwide. Diseased and damaged cartilage regenerate poorly, and current standard care for OA focuses on pain medication, physical therapy or invasive joint replacement procedures. We recently showed that a combination of BMP-2 and VEGF inhibition activated skeletal stem cells (SSCs) and induced full thickness cartilage regeneration in critical sized defects in mice and human xenografts (Murphy et al. Nature Medicine 2020). However, the clinical use of BMP-2 is still problematic due to potential off target effects including stimulation of inflammatory cell types such as monocytes and macrophages. This highlights the necessity for more precise targeting strategies that specifically address SSCs and their lineage cells, while avoiding the activation of immunogenic cells, ultimately optimizing their regenerative potential.To address this need, we are developing the synthetic BMP-2s that primarily activate skeletal lineage cells while avoiding activation of immune cells and allowing for tuning in levels of BMP receptor (BMPR) activation. We use machine learning based algorithm's including Alpha-Fold and Rosetta to identify areas of BMP2/receptor engagement and design high affinity nanobodies to specific epitopes that engages with BMPR (Fig.1). We then developed a fusion construct composed of bispecific nanobodies (NBs) that constrain BMPR to be in active configuration thus enabling downstream signaling (Fig.2a). The linker between NB1 and NB2 is cleavable by an enzyme often secreted by monocytes or macrophages, allowing the synthetic BMP-2s to be inactivated near immune cells (Fig.2b). We measured the functional activities of the synthetic BMP-2s using Smad-dependent (p-smad1/5) and independent (p-p38) activities, showing the proof of concept (Fig.2c,d). The synthetic BMP-2s can also tune its activity based on the linker distance, offering a solution to the problem of ectopic bone formation. After selecting the best linker distance and NB combination, the activity of synthetic BMP-2 was verified with in vitro osteogenesis, chondrogenesis and in vivo subcutaneous implantation model.To summarize, we created activity-controllable BMP-2s that have the potential to serve as a next-generation therapy for regenerative medicine, particularly in the context of the diverse genetic and functional makeup of cells in the skeletal stem cell niche.

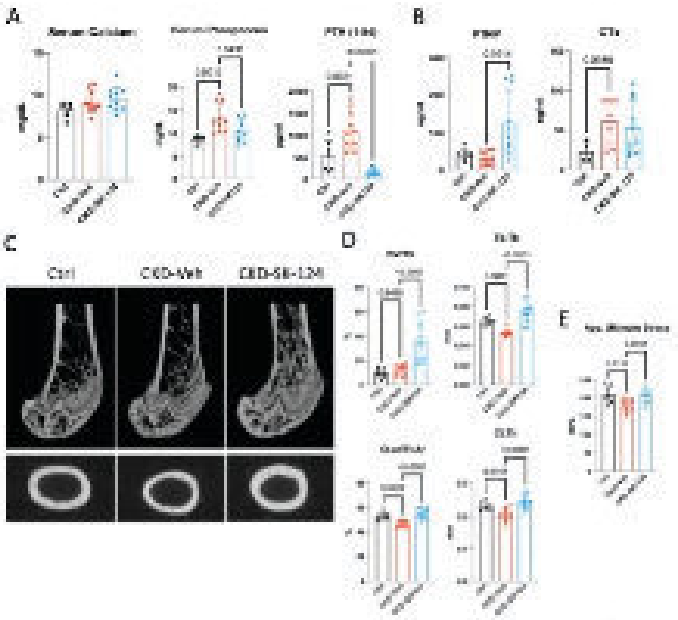
SIK2/SIK3 inhibitor increases cortical bone mass in a mouse model of CKD-MBD *Sung-Hee Yoon[1], Han Xie[4], Michael Bruce[4], Daniel Brooks[4], Michael Mannstadt[3], Marc Wein[4]. [1]Massachusetts General Hospital - Harvard Medical School, [4]Massachusetts General Hospital, United States. [3]Massachusetts General Hospital Harvard Medical School, United States. [4]Massachusetts General Hospital,

Chronic Kidney Disease (CKD) is defined as a decrease in renal function with low glomerular filtration rate, albuminuria, and/or structural abnormalities in kidney. Compromised renal function results in inadequate filtration of waste products and minerals and is associated with bone and mineral disease (CKD-MBD). Salt-Inducible Kinases (SIKs) were identified in bone and kidney as key downstream mediators of PTH receptor signaling. SIK inhibition by cAMP/PKA signaling upon PTH receptor activation in kidney leads to increased Cyp27b1 expression and thus 1,25-vitamin-D production. Similarly in bone, SIK inhibition increases Rankl and decreases Sost expression, thus stimulating bone remodeling and net gains in bone mass. These PTH-like effects of SIK inhibitors may be desirable in CKD-MBD with renal osteodystrophy and low 1,25-vitamin-D levels. Thus, we hypothesized that targeting SIKs, downstream of PTH receptor, would improve mineral metabolism and skeletal outcomes in CKD-MBD. To test this, we examined the effects of SIK inhibitor (SK-124) in 0.2% adenine diet induced CKD model in 8-week old CD1 female mice. After 6 weeks of adenine diet-induced CKD, vehicle-treated mice showed expected changes including hyperphosphatemia, increased BUN, hyperparathyroidism, increased CTx bone resorption marker, and decreased trabecular thickness, cortical bone area and thickness, and compromised apparent material properties in femurs. In contrast, daily SK-124 treatment (40mg/kg) in the presence of adenine diet significantly alleviated hyperphosphatemia and hyperparathyroidism, and increased only the bone formation marker P1NP without changing CTx levels. This net bone formation stimulated by SK-124 led to complete rescue of CKD-associated bone changes including improved trabecular thickness and cortical bone area, in addition to significant improvements in structural and apparent material properties. Surprisingly, SK-124 treatment also improved renal function as assessed by serum BUN and creatinine measurements and urinary protein levels in this CKD model. Thus, direct SIK2/SIK3 inhibition may represent a promising new strategy to improve skeletal health for patients with CKD-MBD.



(A) Calcium, phosphorus, and PTH levels and (B) bone turnover markers, P1NP and CTx, measured in serum collected at the time of sacrifice. (C-D) Representative microCT images and analysis in trabecular and cortical bone of femur. (E) Apparent ultimate stress obtained from 3-point bending test in femur.

Antisense Oligonucleotides Targeting Notch3 Ameliorate Cortical Bone Osteopenia *Ernesto Canalis[1], Magda Mocarska[1], Lauren Schilling[1], Paymaan Jafar-nejad[2], Michele Carrer[2]. [1]UConn Health, United States. [2]Ionis Pharmaceuticals, Inc., United States

Notch receptors are determinants of cell fate and function and play an important role in the regulation of bone development and skeletal remodeling. Lateral Meningocele Syndrome (LMS) is a monogenic disorder associated with NOTCH3 pathogenic variants that result in the stabilization of NOTCH3 and a gain-of-function. LMS presents with neurological developmental abnormalities and bone loss. We created a mouse model (Notch3em1Ecan) harboring a 6691TAATGA mutation in the Notch3 locus recreating the genetic perturbance observed in LMS. Heterozygous Notch3em1Ecan mice exhibit cancellous and cortical bone osteopenia. We explored whether murine Notch3 antisense oligonucleotides (ASO) targeting either Notch3 or the Notch36691-TAATGA mutation downregulate Notch3 or Notch3 mutant transcripts and ameliorate the osteopenia of Notch3em1Ecan mice. ASOs targeting Notch3 decreased the expression of Notch3 wild type and Notch36691-TAATGA mutant mRNA whereas Notch3 mutant ASOs decreased the mutant transcript fairly selectively and neither ASO caused toxicity in cells from Notch3em1Ecan mice. The effect was specific to Notch3 since ASOs did not downregulate Notch1, Notch2 or Notch4. In vivo, the subcutaneous administration of Notch3 ASO at 50 mg/Kg decreased skeletal Notch3 mRNA by 50 - 60% and the administration of Notch3 mutant ASO decreased Notch36691-TAATGA specifically by ~50%. Microcomputed tomography demonstrated that the administration of either Notch3 or Notch3 mutant ASOs ameliorated the cortical bone osteopenia of Notch3em1Ecan mice, decreasing femoral cortical porosity and increasing cortical thickness and bone volume significantly. Notch3 mutant specific ASOs increased p-moment of inertia ($p < 0.07$) indicating a decrease in skeletal fragility in Notch3em1Ecan mice. The in vivo administration of Notch3 or Notch3 mutant ASOs resulted in no apparent toxicity, but did not ameliorate the cancellous bone osteopenia of Notch3em1Ecan mice. We believe that the beneficial effect of the ASO was limited to cortical bone because Notch3 is preferentially expressed by osteocytes and these cells prevail in the cortical bone compartment. In conclusion, Notch3 and Notch3 mutant specific ASOs downregulate Notch3 or Notch3 mutant expression in skeletal cells and their systemic administration ameliorates cortical bone osteopenia in Notch3em1Ecan mice and decrease skeletal fragility. ASOs may become useful strategies in the management of monogenic disorders of the skeleton.

Development of allele-specific antisense oligonucleotide therapy for fibrodysplasia ossificans progressiva *Rika Maruyama[1], Saeed Anwar[2], Quynh Nguyen[2], Rohini Roy Roshmi[2], Daniel Graf[3], Toshifumi Yokota[2, 1], [2]Department of Medical Genetics, University of Alberta, Canada, [3]Department of Dentistry & Dental Hygiene, University of Alberta, Canada

Fibrodysplasia ossificans progressiva (FOP) is a rare autosomal dominant disorder characterized by episodic heterotopic ossification (HO). It affects approximately 1 in 2 million people worldwide and has no racial, ethnic, or gender preference. More than 95% of cases are caused by a recurrent mutation (c.617G>A; R206H) of activin A receptor, type I (ACVR1)/activin receptor-like kinase-2 (ALK2), a bone morphogenetic protein type I receptor. This mutation is dominant and results in an amino acid change (R206H) within the glycine serine domain of ACVR1. The exact mechanism of FOP remains controversial, but this mutation renders ACVR1 hyperactive and responsive to activin A, triggering HO.Until recently, there were no treatment options for FOP. However, a new drug called palovarotene was approved for the treatment of FOP in Canada in 2022. Although palovarotene has shown promising results in preventing HO, a major drawback is its inability to differentiate between wild-type ACVR1 and ACVR1R206H, which could be potentially harmful to patients. In fact, it is not recommended for use in children.A promising therapeutic strategy for FOP is to reduce the activity of mutant ACVR1 in an allele-specific manner. To this end, we have designed gapmers that selectively knock down ACVR1R206H mRNA. Gapmers are short DNA oligonucleotides with chemical modifications at both ends that can degrade mRNA and selectively silence specific genes. We demonstrated that these gapmers efficiently knocked down ACVR1R206H expression at the RNA level, while ACVR1WT was largely unaffected in human FOP fibroblasts. In addition, the gapmers were able to reduce the amount of ACVR1R206H protein more efficiently than the wild type and suppress osteogenic differentiation induced by activin A. Furthermore, a single systemic injection of the gapmers significantly reduced ACVR1R206H expression in vivo and prevented HO in an FOP mouse model.In conclusion, our results suggest that gapmers targeting ACVR1R206H are promising drug candidates for FOP. These gapmers are considered safe and can be administered systemically via subcutaneous or intravenous injections, which is particularly advantageous for FOP patients because viral vector-mediated gene therapy can induce immune responses and inflammation leading to increased HO. This novel strategy may pave the way for antisense-mediated therapy of other autosomal dominant disorders.

Cystatin M/E ameliorates bone resorption in both multiple myeloma and sex steroid deficient models through increasing intracellular estrogen concentrations *Perry Caviness[3], Dongzheng Gai[2], Hongwei Xu[2], Oxana Lazarenko[3], Michael Blackburn[3], Jin-Ran Chen[4], Fenghuang Zhan[2, 3]Arkansas Children's Nutrition Center, [2]Myeloma Center, University of Arkansas for Medical Science, United States, [3]Arkansas Children's Nutrition Center, United States, [4]Arkansas Children s Nutrition Center / UAMS, United States

In multiple myeloma (MM), increased osteoclast differentiation leads to formation of osteolytic lesions, leading to severe complications for the majority of MM patients. Currently, bisphosphonates, such as zoledronic acid (ZA), are used to ameliorate increased bone resorption but, due to potential side effects as well as their inability to repair existing osteolytic lesions novel anti-bone resorption agents are required. It was previously shown that in MM patients the absence of osteolytic lesions was strongly associated with an increase in the expression of cystatin M/E (CST6), a cysteine protease inhibitor. In this study, both MM and ovariectomy induced osteoporosis (OVX) mouse models were used to compare the effects of recombinant mouse CST6 to ZA on ameliorating bone loss. For both models, µCT showed that both CST6 and ZA had similar effects on improving percent bone volume (BV/TV %) (MM: 2.64 +/- 0.52, MM + CST6: 3.57 +/- 0.14, MM + ZA: 3.88 +/- 0.53) (Sham: 3.09 +/- 0.60, OVX: 2.33 +/- 0.44, OVX-CST6: 3.23 +/- 0.50, OVX-ZA: 3.85 +/- 0.23). Single cell RNA sequencing showed that treatment with either CST6 or ZA altered the bone marrow cell type ratio in MM mouse models. Both CST6 and ZA inhibited differentiation of non-adherent bone marrow cells into mature osteoclast. However, ZA had a negative impact on the viability of non-osteoclast cells. In breast cancer, loss of CST6 is associated with loss of estrogen receptor ? (ER?), limiting the downstream effects of estrogen. Based on this we propose that CST6 works to improve MM or OVX bone loss models by increasing the expression of estrogen receptors as well as intracellular estrogen concentration in pre-osteoclasts, inhibiting their maturation. For Raw 264.7 cells (+/- RANKL) mRNA levels for ER? and ER? were significantly increased following 200 ng/ml CST6 treatment. In addition to this, intracellular total estrogen concentration was also significantly increased in Raw 264.7 cells following CST6 treatment (Control: 765 +/- 233 pg/ml, 200 ng/ml CST6: 1176 +/- 152 pg/ml) (RANKL; Control: 1366 +/- 44 pg/ml, 200 ng/ml CST6: 1448 +/- 22 pg/ml). Further research is needed to determine the mechanism explaining this increase in intracellular estrogens. Supported by National Cancer Institute (R01 CA236814), U.S. Department of Defense (CA180190) as well as funding from the the Myeloma Crowd Research Initiative Award and the Riney Family Multiple Myeloma Research Program Fund awarded to FZ.

Long-term OPG:Fc Treatment with Discontinuation Lead to Elevated Microporosities in a Mouse Model Simulating Denosumab Treatment *Johannes Krug[1], Haniyeh Hemmatian[2], Albert Kim[3], Jad Zamerli[3], Annegreet Vlug[4], Katharina Jähn-Rickert[5], Bjoern Busse[5], Michelle McDonald[3], [1]University Medical Center Hamburg-Eppendorf, GER, Germany, [2]University of Melbourne, Department of Medicine-Austin Health, Australia, [3]Garvan Institute of Medical Research, Bone Microenvironment Group, Australia, [4]LUMC, [5]University Medical Center Hamburg-Eppendorf, Germany

Following therapy discontinuation, denosumab-treated osteoporosis patients experience a rebound bone loss with an increase in vertebral fragility fractures. While high-resolution imaging techniques have recently highlighted the importance of bone microporosity as a quantifiable marker of bone mechanical integrity, the structural basis of rebound bone loss associated fragility fractures following denosumab discontinuation remains poorly understood.This study aimed to evaluate bone microporosities, including the osteocyte lacunar and cortical canal networks, in a mouse model of denosumab treatment discontinuation using microcomputed tomography at a nominal resolution of 0.7 µm. Microporosities were quantified in the proximal tibia of mice receiving treatment with an osteoprotegerin Fc (OPG:Fc, 10mg/kg 3 times a week, n=6) or vehicle (n=6) for i) 2 weeks (2+0 weeks), ii) 2 weeks and 12 weeks discontinuation (2+12 weeks), or iii) 8 weeks and 15 week discontinuation (8+15 weeks).In the cancellous bone, lacunar volume was not significantly larger with 2 weeks of treatment either with or without discontinuation, but following 8 weeks of treatment and then discontinuation mean lacunar volume was increased by 13.5% (p=0.002) compared to vehicle. Both discontinuation groups also presented with elevated osteocyte densities (trend in 2+12 weeks: p=0.0529; 8+15 weeks: p=0.008), a finding that was not evident in the 2+0 weeks group. In the cortex, cortical thickness was elevated in the 2+0 week treatment group (p=0.006), while a thinner cortex was evident in both discontinuation groups (2+12 weeks: p=0.024; 8+15 weeks: p=0.005). The cortical bone lacunar characteristics were not altered in any group. The cortical canal volume and number were unchanged with both 2+0 and 2+12 weeks treatment groups, however after 8 weeks of treatment with discontinuation (8+15 weeks) canal volume and number were increased (p=0.006 and p<0.001).In conclusion, in a mouse model, 8 weeks of OPG:Fc treatment with 15 weeks of discontinuation led to elevated trabecular lacunar porosity and cortical canal porosity, outcomes which were not seen following 2 weeks of treatment with or without discontinuation. Therefore, this study shows that bone tissue microporosities compromising mechanical integrity might play a role in the pathogenesis of rebound bone loss and vertebral fractures following denosumab discontinuation, primarily after longer term treatment.

Interrogating Osteoclast Biology by Live Cell Imaging Reveals Novel Insight into their Cellular and Resorption Dynamics and Real-Time Effects of OPG-Fc and RANKL *Sarah Dallas[1], Kun Wang[1], Charles O'Brien[2], Anthony Meljanac[1], Roya Sabzian[1], Eleanor Ray[1], Vedvignesh Gorjala[1], Yixia Xie[1], Lynda Bonewald[3], David Moore[1]. [1]University of Missouri - Kansas City, United States; [2]Univ of Arkansas for Medical Sciences, United States; [3]Indiana University School of Medicine, United States

Although much progress has been made in defining molecular pathways critical for osteoclast (OCL) function and identifying molecular targets for anti-resorptive therapies, interrogating OCL biology by live cell imaging can reveal novel insights into their function. Transgenic mice with OCL expression of tdTomato (LysM-Cre/tdTom), osteocyte expression of GFP (Dmp1-mGFP) or with GFP-tagged type I collagen (Col-GFP) were crossed in 2-color combinations and confocal or widefield live cell imaging was done in calvarial explants to define OCL dynamic & resorptive behavior in bone and real-time responses to RANKL & OPG-Fc, a RANKL inhibitor. Long term (up to 3d) imaging in LysM-Cre/tdTom/Col-GFP calvaria revealed complex OCL dynamics including fission, fusion, recycling/cytoplasmic exchange, amoeboid-like streaming and extension/retraction of cell processes. Our image resolution allows visualization of OCL sealed zones, revealing that a single OCL can have one or multiple (>=3) sealed zones resorbing simultaneously. In bone tissue, the % of OCL cell-cell encounters resulting in fusion was 6.0% +/- 3.7. In contrast, OCL cultured on plastic had a 10-fold higher % fusion of 67.0% +/- 20.6. OPG-Fc (500ng/ml) caused a rapid change within ~1h to an intricately branched OCL morphology with loss of sealed zones. OPG-Fc increased the complexity of OCL dynamics, with a ~3-fold increase in fissions/OCL/10h (0.32 +/-0.14 vs. 0.12 +/-0.05, p=0.008) and fusions/OCL/10h (0.25 +/-0.10 vs. 0.08 +/-0.07 p= 0.008), while downregulating expression of OCL marker genes, TRAP, DC-STAMP, Atp6v0d2, CTSK, & NFATc1. Computational analysis of motion trajectories showed that OPG-Fc treated OCL had similar velocities as controls. However, OCL in control bones had open, directional trajectories compared to OPG-Fc treated OCL which had compacted trajectories indicating OCL moving in circles. Automated quantitation of real-time GFP-collagen resorption showed arrest of resorption with OPG-Fc. Subsequent treatment with RANKL (200ng/ml) induced fusion, re-formation of sealed zones and re-activation of GFP-collagen resorption. In control bones with already active OCL, RANKL did not induce much fusion, but induced a compacted cell morphology, with intensified actin rings & resorption activity, suggesting direct effects on mature OCL. These results show that mature OCL respond dynamically and reversibly to changes in RANKL signaling and highlight the importance of observing OCL in their natural bone environment.

RANKL and OPG mRNA are produced by separate cell populations in murine and human bone *Cecile Bustamante-Gomez[1], Humberto Reyes-Pardo[1], Melda Onal[1], Michela Palmieri[1], Lowry Barnes[1], Jeffrey Stambough[1], Jinhu Xiong[1], Elena Ambrogini[1], Charles O'Brien[1]. [1]University of Arkansas for Medical Sciences, United States

The RANKL/OPG axis controls the location and magnitude of osteoclast formation during skeletal development, growth, and homeostasis. Gene inactivation studies in mice have revealed that different cell types are important sources of either RANKL or OPG for the control of physiologic and pathologic bone resorption. However, due to uncertainties regarding the cell types targeted by various Cre driver strains, the precise identity of the cells providing the RANKL and OPG in bone microenvironments remains unclear. To help clarify this question, we used RNAScope in situ hybridization to detect RANKL and OPG mRNA in murine and human bone sections. Consistent with previous genetic studies, RANKL mRNA was easily detected in bone marrow cells with a morphology consistent with Cxcl12-abundant-reticular (CAR) cells and in a subpopulation of osteocytes. OPG mRNA was easily detected in osteocytes, but only in a small subpopulation of osteoblasts. These findings were similar in murine and human bone sections. Because previous studies have shown that PTH stimulates RANKL and suppresses OPG mRNA abundance in vitro and in vivo, we examined the impact of a single injection of PTH on the expression of these factors in murine bone. Bones were collected and analyzed by RNAScope 1, 6, 12, and 24 hours after injection. One hour after PTH injection, RANKL mRNA signal was strongly increased in CAR-like cells near the bone surface but the levels in osteocytes were not changed. At later timepoints, RANKL mRNA in all cell types was similar to uninjected mice. OPG mRNA levels in osteocytes were potently suppressed one hour after PTH injection but returned to normal by 6 hours. These results suggest that PTH induction of bone resorption is accomplished by stimulating RANKL production by CAR cells and inhibiting OPG production by osteocytes, at least in the short-term. We also detected RANKL mRNA in hypertrophic chondrocytes and OPG mRNA in growth plate chondrocytes and articular chondrocytes. The juxtaposition of OPG and RANKL expression in growth plate chondrocytes suggests that OPG production by pre-hypertrophic chondrocytes acts as a barrier to prevent osteoclastic resorption of the growth plate. Penetration of the growth plate in OPG null mice is consistent with this idea. Moreover, the abundant expression of OPG by articular chondrocytes in humans and mice suggests an important role for this factor in the protection of this tissue from degradation by osteoclasts.

RANKL from bone marrow adipogenic lineage precursors is required for bone resorption and pathological bone loss in adult mice *Jiawei Lu[1], Qi He[1], Corben Braun[1], Ken Chen[1], Michael Duffy[1], Jun Li[1], Hanli Guo[1], Jiankang Fang[1], Yilu Zhou[1], Qiushi Liang[1], Yu Lieh Lin[1], Ling Qin[2]. [1]University of pennsylvania, United States; [2]University of Pennsylvania, United States

Bone resorption by osteoclasts is a critical step in bone remodeling. It is well known that osteogenic cells support osteoclastogenesis via synthesizing RANKL. Previous work identified a novel bone marrow mesenchymal subpopulation, marrow adipogenic lineage precursors (MALPs), as a major source for RANKL. Mice with RANKL deficiency in MALPs using Adipoq-Cre had a drastic increase in trabecular bone mass (BV/TV) at 1 and 3 months of age. Using a Tomato (Td) reporter to label MALPs, we found that MALPs first appear inside the bone marrow at birth (P1). To exclude developmental defects and to investigate the role of MALPs-derived RANKL in adult bone, we generated inducible RANKL iCKO mice using Adipoq-CreER. These mice grew normally with no phenotypes. We subjected female iCKO and WT siblings to Tamoxifen (Tam) injections at 3 months of age followed by sham or ovariectomy (ovx) surgery (n=4-8 mice/genotype/surgery). Tam effectively reduced bone marrow RNAKL mRNA by 66% 1 month later. Six weeks post-surgery, we observed striking 3.2- and 1.5-fold increases in femoral and vertebral trabecular BV/TV, respectively, in iCKO mice compared to WT mice. While WT mice developed pathological trabecular bone loss at both sites (femur: 60.7%; vertebra: 25.3%) after ovx, iCKO mice maintained most of their trabecular bone, leading to 5.7- and 1.5-fold more bone than WT ovx mice at these sites. Cortical bone was not affected by either ovx or RANKL knockdown. TRAP staining of femoral sections revealed that compared to WT mice, iCKO mice display 36.8% and 28.4% reduction in osteoclast surface (Oc.S/BS) after sham and ovx surgery, respectively. Ovx increased bone marrow adipocytes by 2.7-fold in WT mice. Interestingly, iCKO mice showed a similar increase of bone marrow adiposity despite strong bone gain, suggesting that high bone mass and high adiposity could co-exist under certain conditions. To study the role of MALP-derived RANKL after bone loss has initiated, we subjected WT and iCKO mice at 3 months of age to sham or ovx mice first and then treated them with Tam 3 weeks later (n=4-6 mice/genotype/surgery). At 6 weeks post-surgery (3 weeks after Tam), we observed a similar high bone mass phenotype in iCKO mice with either sham or ovx, indicating that MALPs-derived RANKL could be targeted for postmenopausal osteoporosis treatment. In summary, our studies demonstrate that MALPs produce RANKL to control adult bone remodeling and postmenopausal bone loss.

RANKL signaling drives skeletal muscle into the oxidative profile *Paulo Henrique Cavalcanti de Araujo[1], Maria Eduarda Ramos Cezine[1], Mariana Kiomy Osako[1]. [1]Ribeirao Preto Medical School, University of Sao Paulo, Brazil

The skeletal muscle is vital for energetic homeostasis. A reduced mitochondrial reticulum and oxidative phosphorylation activity in this muscle is seen in metabolic diseases such as obesity and type II diabetes. The receptor activator of NF-?B ligand (RANKL) stimulation induces mitochondrial biogenesis and increases the oxidative capacity in osteoclasts and adipocytes. RANKL may bind to the membrane bound receptor activator of NF-kB (RANK) or to osteoprotegerin (OPG), a decoy receptor that inhibits RANK-RANKL activation. RANK is highly expressed in skeletal muscle, however, the contribution of RANKL to healthy skeletal muscle fiber remains elusive. Here we show that RANKL stimulation in C2C12-derived myotubes induced activation of mitochondrial biogenesis pathways as detected by RNA-seq and western blot. It also expanded the mitochondrial reticulum, as evaluated by mitotracker staining and mitochondrial DNA quantification, and boosted the spare respiratory capacity. The soleus from OPG-/- and OPG+/- mice showed higher respiratory rates compared to C57BL6/J wild type (WT) mice, which correlates with higher serum RANKL levels. RANKL infusion using a mini-osmotic pump in WT mice increased the number of mitochondria and oxidative fibers (type 2A) and boosted the respiratory rate. We also observed an increase in succinate dehydrogenase (SDH) activity in skeletal muscle, in trained, high fat diet-fed WT mice. We found that RANKL increases mitochondrial biogenesis, induces an oxidative profile in skeletal muscle and may protect against obesity-induced metabolism impairment. Our findings reveal a new contribution of RANKL as an osteokine-like protein that impacts muscle fiber metabolism.

Efficacy of Osteoporosis Drug Treatment for Reducing Risk of Hip Fracture is the Same in Women and Men *Tony Keaveny[1], David Lee[2], Eric Orwoll[3], Sundeep Khosla[4], Michael McClung[5], Ethel Siris[6], Mary Bouxsein[7], Annette Adams[8], David Kopperdahl[2]. [1]University of California, Berkeley, United States, [2]O.N. Diagnostics LLC, United States, [3]Oregon Health & Science University, United States, [4]Mayo Clinic College of Medicine, United States, [5]Oregon Osteoporosis Center, , [6]Columbia University College of Physicians and Surgeons, United States, [7]Beth Israel Deaconess Medical Center, Harvard Medical School, United States, [8]Kaiser Permanente Southern California, United States

Purpose: The US Preventive Services Task Force does not recommend diagnostic screening of osteoporosis for men due in part to insufficient evidence that osteoporosis drug treatment prevents hip fractures in men. As a result, many high-risk men go untested and untreated for osteoporosis. Addressing that evidence gap, we compared the real-world reduction in risk of hip fracture associated with standard-of-care osteoporosis drug treatment in women versus men.Methods: This was an observational case-cohort study drawing from 341,364 patients age >= 65 in the Kaiser Permanente Southern California healthcare system who had a hip-containing CT scan between 1/1/2005 and 6/30/2018 as part of their care. Cases were selected as all those with a hip fracture after the CT scan; an equal number of sub-cohort patients was randomly selected (sex- and facility-matched) without regard to fracture status. Using data from half the sample, we analyzed fracture risk at 2, 5, and 10 years follow-up after the CT scan; cases were those who fractured their hip during follow-up; controls reached follow-up without fracture. DXA-equivalent bone mineral density (BMD, lowest hip T-score) and femoral strength were measured from the existing CT scans using VirtuOst, and clinical data were obtained from the medical records. Sex-specific multivariate nominal logistic regression was used to obtain an odds ratio associated with osteoporosis drug treatment during follow-up (positive if >= 90 days of any treatment during follow-up). Either BMD or bone strength was included in the statistical model, plus most major risk factors at the time of the CT scan (age, BMI, smoking, alcohol, rheumatoid arthritis, diabetes, glucocorticoid use, secondary osteoporosis, previous major fracture).Results: Complete data were available for 5,144 patients. The odds ratio (for hip fracture) associated with osteoporosis drug treatment versus no treatment varied from 0.30 to 0.46 over the 2- 5- and 10-year follow-ups and was not significantly different between women and men (Table). Showing robustness, the odds ratio was similar regardless of whether BMD or bone strength was used in the statistical model. The 60% risk reduction for women at 2-year follow-up is consistent with results from randomized controlled trials, validating our approach for assessing relative efficacy between the sexes.Conclusion: In this large real-world clinical setting, standard-of-care osteoporosis drug treatment reduced the risk of hip fracture equally in women and men.

The association between treatment-related differences in total hip bone mineral density change and fracture risk reduction for BMD measurement intervals of 12, 18 and 24 months: the FINH-ASBMR SABRE Project *Tatiane Vilaca[2], Marian Schini[2], Eric Vittinghoff[3], Li-Yung Lui[4], Susan Ewing[3], Douglas Bauer[5], Mary Bouxsein[6], Richard Eastell[2], Dennis Black[7]. [2]University of Sheffield, United Kingdom, [2]University of Sheffield, , [3]Department of Epidemiology & Biostatistics, University of California, United States, [4]CALIFORNIA PACIFIC MEDICAL CENTER, United States, [5]University of California, San Francisco, United States, [6]Beth Israel Deaconess Medical Center, Harvard Medical School, United States, [7]UC San Francisco,

We have shown a strong association between treatment-related differences in 24 month total hip BMD (THBMD) change and fracture risk reduction. However, the relationships between shorter treatment-related changes in BMD and fracture risk reduction are unknown. In this analysis, we examined whether shorter intervals of BMD measurement were also associated with fracture reductions.We used individual patient data from 22 randomised, placebo-controlled, double-blind trials of antiosteoporosis medications [10 bisphosphonates, 1 odanacatib, 2 hormone therapy, 3 parathyroid hormone receptor agonists, 1 denosumab, and 4 selective estrogen receptor modulator, 1 romosozumab]. For each trial, we calculated the active-placebo difference in mean percent change in THBMD at 12, 18 and 24 months. We also estimated the treatment-related fracture reductions for each trial for the entire follow-up period, using logistic regression for morphometric vertebral fractures and Cox regression for all clinical, non-vertebral, hip and "all" (combination of non-vertebral and clinical or morphometric vertebral) fractures. We performed linear meta-regression to estimate the study-level association (r2 and 95% confidence interval) between treatment-related differences in THBMD changes for each BMD measurement interval and fracture risk reduction. The meta-regression revealed significant associations ($p<0.05$) between treatment-related changes in THBMD at 12, 18, and 24 months and reductions in vertebral, hip, non-vertebral, all and all clinical fractures (table). These findings confirm that treatment related THBMD changes at 12 and 18 months, as well as 24 months are associated with fracture risk reductions in vertebral, hip, non-vertebral, all and all clinical fractures across randomised trials of antiosteoporosis therapies. For all fracture sites, the r2 were very similar at 18 and 24 months.These results support that 12-, 18- or 24-month BMD measurement intervals could be considered for a future trial using BMD as a surrogate endpoint to assess fracture efficacy. However, longer BMD measurement intervals provide more robust association with fracture reduction.

Table Results from meta-regression of between-group (active-placebo) difference in mean percent change in total hip bone mineral density with fracture risk reduction at 12-, 18-, and 24-month

Imminent fall risk after fracture *Merle Schene[1], Caroline Wyers[1], Annemariek Driessen[1], Patrick Souverein[2], Marle Gemmeke[2], Joop van den Bergh[1], Hanna Willems[3]. [1]Department of Internal Medicine, VieCuri Medical Center, Netherlands, [2]Division of Pharmacoepidemiology and Clinical Pharmacology, Utrecht Institute for Pharmaceutical Sciences (UIPS), Faculty of Science, Utrecht University, Netherlands, [3]Amsterdam UMC location University of Amsterdam, Internal Medicine and Geriatrics, Netherlands

A high imminent risk of subsequent fracture in the first 2 years after a fracture is well established and subjects with a recent fracture have a high fall risk. We hypothesize that, like subsequent fracture risk, fall risk is also highest immediately after a fracture. This retrospective matched cohort study aims to assess if fall risk is time-dependent in subjects with a recent fracture, compared to fracture-free controls. We used primary care electronic health records from the UK Clinical Practice Research Datalink (CPRD) GOLD. Subjects aged >=50 years with an incident fracture between 1993-2015 were identified and matched one-to-one to fracture-free controls by age, sex and GP-practice. One-year incidence rates (IRs)/1000 person years of first falls and fractures were compared between groups using incidence rate ratios (IRRs). The cumulative incidence and relative risk (RR) of first falls was calculated every 6 months of follow-up, with mortality as competing risk. Analyses were stratified by age, sex and index fracture. In total, 312,230 subjects with an index fracture and 312,230 controls were included (71% women, aged 70+/-12 years, follow-up 6 [3-10] years). The one-year IR for first falls was higher in the fracture cohort compared to the control cohort: in women with a non-major osteoporotic fracture (non-MOF) the IRR was 1.9 (95% confidence interval [CI] 1.8-2.0), and with MOF 1.8 (95% CI 1.7-1.8). In men with non-MOF the IRR was 2.5 (95% CI 2.3-2.7) and with MOF 2.6 (95%CI 2.4-2.8). Similarly, one-year IR of fracture was higher in the fracture cohort: women non-MOF IRR=7.4 (95% CI 6.6-8.3) and MOF IRR=7.0 (95% CI 6.3-7.9) and men: non-MOF 10.2 (95% CI 7.9-13.1), MOF 11.8 (95% CI 8.9-15.5). Correspondingly, the RR of falls was highest in the first few years after fracture compared to controls and declined over time; in the first year women had a 2.2-fold and men a 3.1-fold higher risk, in the second year a 1.5-fold and 2.0-fold risk. Imminent fall risk was present for all ages and index fractures. Similar RR patterns over time were confirmed for imminent fracture and mortality risk. This study demonstrates an imminent fall risk in the first 2 years after fracture, with mortality as competing risk. Corresponding time-dependent risk patterns were confirmed for subsequent fractures and mortality. This

emphasizes the need for combined fall and fracture risk assessment and prevention strategies in adults over 50 years with a recent fracture.

Associations between use of anti-resorptive agents for patients with osteoporosis and all-cause mortality risk: a nationwide population-based study *Kyoung Jin Kim[1], Gi Hwan Bae[2], Seong Hee Ahn[3], So Young Park[4], Ha-Young Kim[5], Kyoung Min Kim[6]. [1]Korea University College of Medicine, Republic of Korea. [2]Gachon University College of Medicine, Republic of Korea. [3]Inha University School of Medicine, Republic of Korea. [4]Kyung Hee University School of Medicine, Republic of Korea. [5]University of Ulsan College of Medicine, Republic of Korea. [6]Yonsei University College of Medicine, Republic of Korea

Although the association between osteoporosis-related fractures and mortality is well-established, it remains uncertain whether osteoporosis drug treatments reduce the risk of mortality. Therefore, we investigated to determine the association between anti-resorptive agents and mortality risk in postmenopausal women with osteoporosis. A total of 117,871 women who diagnosed as osteoporosis by dual-energy X-ray absorptiometry screening were included from the National Screening Program for Transitional Ages health examination from 2008 to 2017. Among them, 11,337 patients who had taken anti-resorptive agents (AR), either bisphosphonate or selective estrogen receptor modulator (SERM), for at least 1 year (AR user group) were matched at a 1:1 ratio to those who had never taken osteoporotic agents (non-user group) by using propensity scores. We estimated the risk of all-cause mortality using multivariable Cox proportional hazard regression models. The mean age of women was 66 years and mean body mass index was 23.2 +/-3.0 kg/m2. In the AR user group, 73.8% was prescribed with bisphosphonates, whereas 26.2% was treated with SERMs. During a median follow-up period of 1.6 years, a total of 121 deaths occurred in the AR user group, and 201 deaths occurred in the non-user group. The mortality rate was 1.99 deaths per 1000 person-years in AR users and 3.36 deaths in non-users, which corresponded to a 45% lower mortality rate in AR users (HR, 0.55; 95% CI, 0.44-0.69). Furthermore, the longer the individuals took AR, the lower the risk of all-cause mortality compared to the control group [HR = 0.55 in 12-24 months, HR = 0.55 in 24-36 months, and HR = 0.50 in >=36 months, p-for trend <0.01]. The mortality risk related to cardiovascular disease (CVD) was lower in the AR group compared to the non-user group (HR = 0.72; 95% CI: 0.64-0.81); however, the interpretation should be approached with caution due to the limited number of events. In the subgroup analysis, the use of AR-related to reduced mortality was more prominent in the calcium or vitamin D replete group compared to the non-replete groups (p for trend <0.001 for both). Taking AR agents contributed to lowering risk of all-cause mortality among postmenopausal women with osteoporosis. Our findings provided real-world evidence regarding the necessity of management of osteoporosis with anti-osteoporotic agents in postmenopausal women.

Figure 1. Cumulative incidence curve of mortality in the AR users (n=11337) with the non-users (n=11337). Hazard ratio (HR) with 95% confidence interval (CI) is shown.

Kidney Stone Disease and Risk of Osteoporotic Fractures among U.S. Medicare Beneficiaries *Naim Maalouf[1], Mary Oerline[2], Ryan Hsi[3], Sara Best[4], Joseph Crivelli[5], John Hollingsworth[6], Vahakn Shahinian[2]. [1]University of Texas Southwestern Medical Center, United States. [2]University of Michigan, United States. [3]Vanderbilt University, United States. [4]University of Wisconsin, United States. [5]University of Alabama, United States. [6]NorthShore University HealthSystem, United States

Background: Several observational studies suggest that the presence of kidney stone disease (KSD) may put an individual at higher risk of osteoporotic fracture (OF). Whether this risk varies by fracture site, is influenced by patient age, or differs between men and women remains controversial.Methods: We investigated the association between KSD and OF using U.S. Medicare data from a 20% random sample of beneficiaries. We identified individuals age>=65 years with >=2 physician-coded diagnoses of KSD within a year or >=1 surgical procedure code for KSD between 2011 and 2015. Each patient with KSD was matched with 3 control beneficiaries without KSD based on age, gender, and race. Patients with a diagnosis of OF, primary hyperparathyroidism, or parathyroidectomy in the year preceding or the year following the index KSD event were excluded from KSD patients and controls. The incidence of arm, vertebral, and hip fractures was determined based on claims data over a median of 5.0 years of follow-up from the index KSD date. Cox regression was used to estimate the hazard ratio (HR) for fractures after adjusting for risk factors for osteoporosis.Results: In total, 140,053 KSD cases and 420,091 controls were included in this analysis. Mean age at index stone date was 75.1+/-6.8 years, 38.4% of patients were female, and 95.6% were non-Black. Over the study period, 15,335 OF occurred in KSD patients and 25,391 OF in controls [unadjusted HR: 1.62 (95% CI: 1.59-1.65)]. After adjusting for multiple risk factors/comorbidities (including age, gender, race, osteoporosis diagnosis, obesity, hypertension, CKD, GI disease or bowel resection), the adjusted HR for OF was 1.22 (95% CI: 1.19-1.24). The multivariable adjusted HR (95% CI) for OF in KSD patients vs controls decreased significantly with older age [1.26 (1.22-1.30) for age 65-74, 1.20 (1.16-1.24) for age 75-84, and 1.16 (1.11-1.22) for age >=85 (p for interaction<0.01)], and was significantly higher in women [1.36 (1.32-1.41)] than men [1.11 (1.08-1.14)] (p for interaction <0.01). KSD patients had a significantly higher multivariable adjusted HR for arm [1.31 (1.25-1.37)], vertebral [1.24 (1.20-1.27)], and hip [1.18 (1.14-1.22)] fracture.Conclusions: In this large study of older Medicare beneficiaries, KSD was associated with a higher incidence of arm, vertebral, and hip fractures. The underlying mechanism(s) require further investigation, but these results need to be considered in counseling patients with KSD.

Rethinking Fragility Fracture Age Cut-offs: Fractures Beget Fractures Regardless of the Age at Which They Occur *Carrie Ye[1], Suzanne Morin[2], Lisa Lix[3], Eugene McCloskey[4], Helena Johansson[4], Nicholas Harvey[5], JOHN KANIS[6], William Leslie[3]. [1]University of Alberta, Canada. [2]McGill University, Canada. [3]University of Manitoba, Canada. [4]University of Sheffield, United Kingdom. [5]University of Southampton, . [6]UNIVERSITY OF SHEFFIELD, United Kingdom

Fragility fractures are sometimes restricted to those occurring over a certain age (for example, 40 to 50 years), whereas FRAX considers a previous fracture in adult life regardless of age. Although the incidence of fractures increases with age, there is no evidence that fractures occurring in early adulthood are less predictive of future fractures.AIM: To determine whether the age at which a prior fracture occurs modifies its effect on future fracture risk. METHODS: Subjects from the Manitoba BMD Registry with a first DXA between 1996 and 2018 were linked to provincial administrative health data from 1981 onwards to ascertain

all diagnosed fractures occurring before and after the first DXA. Individuals with fractures prior to their first DXA were stratified by the age at first fracture (10-year intervals from age 20-29 to >80 years). Cox regression models estimated hazard ratios (HR) for any incident fracture, osteoporotic fracture, major osteoporotic fracture (MOF) and hip fracture, by age interval at first adult fracture. Models were adjusted for age, sex, body mass index, parental hip fracture, smoker, prolonged glucocorticoid use, rheumatoid arthritis, secondary osteoporosis, high alcohol use, anti-osteoporosis treatment and femoral neck T-score ascertained at the time of first DXA. Linear trend in age effect was tested in the same models.RESULTS: The cohort included 88,696 individuals, 90.3% women, mean age 64.6 years, and mean femoral neck T-score -1.4. Almost one-quarter (21,105, 23.8%) had suffered a prior fracture with a mean age of 57.7 years (range 20.0-102.4 years) at time of first prior fracture. During mean 9.0 years follow-up there were incident fractures in 13,239 (14.6%), including 12,245 (14.0%) osteoporotic fractures, 9440 (10.6%) MOFs and 3068 (3.5%) hip fractures. The adjusted HR for all incident fractures, osteoporotic fractures, MOF and hip fractures were significant in all age groups of first prior fracture and ranged from 1.46 to 2.18 for MOF, and 1.33 to 3.43 for hip fracture (Table). There was no effect modification by age of prior fracture (p-trend >0.1). Sensitivity analyses examining age at last prior fracture, in those with a single prior fracture or those with multiple prior fractures showed similar results.CONCLUSION: Fractures in adulthood predict future fractures regardless of the age at which they occur. Thus, fractures in early adulthood should not be excluded when assessing an individual's ongoing fracture risk.

Effect of BMI-Discordant Abdominal Tissue Thickness on Fracture Probability: The Manitoba BMD Registry *William Leslie[1], Neil Binkley[2], John Schousboe[3], Eugene McCloskey[4], Helena Johansson[5], Nicholas Harvey[6], JOHN KANIS[7]. [1]University of Manitoba, Canada. [2]University of Wisconsin, Madison, United States. [3]Park Nicollet Clinic HealthPartners Institute University of Minnesota, . [4]University of Sheffield, United Kingdom. [5]University of Sheffield Medical School, United Kingdom. [6]University of Southampton, . [7]UNIVERSITY OF SHEFFIELD, United Kingdom

FRAX® considers body mass index (BMI) as a primary input. BMI may not reflect individual variation in body composition and distribution including central obesity.AIM: To examine the effect of BMI-discordant abdominal thickness on FRAX-derived fracture probability for major osteoporotic fracture (MOF) and hip fracture.METHODS: We identified individuals aged 40 years and older at the time of baseline DXA with FRAX assessment in the Manitoba BMD Program. We defined abdominal thickness index (ATI) as the difference between abdominal thickness measured by spine DXA and thickness predicted by BMI using sex-stratified regression. ATI was categorized from lowest (+2 cm) with referent close to zero (-1 to +1 cm). Incident fractures were assessed from linked population-based health data. Hazard ratios (HR) for fracture were estimated from Cox regression adjusted for FRAX probability including competing mortality. Calibration plots compared observed versus predicted 10-year probability according to ATI category.RESULTS: The study contained 73,105 individuals, mean age 64.2 years. During mean 8.7 years observation, 7047 (9.6%) individuals sustained one or more incident MOF, including 2157 (3.0%) hip fractures. Adjusted for FRAX probability, increasing ATI was associated with incident MOF and hip fracture (p-trend <0.001). For the highest ATI category, MOF risk was increased (HR 1.23, 95% CI 1.12-1.35). Similar findings were noted for hip fracture probability (HR 1.28, 95% CI 1.09-1.51). There was significant age-interaction with much larger effects prior to age 65 years (HR 1.44, 95% CI 1.23-1.69 for MOF; 2.29, 95% CI 1.65-3.18 for hip fracture). In contrast, for the subset of individuals with diabetes there was also increased risk for those in the lowest ATI category (HR 1.73, 95% CI 1.12-2.65 for MOF, 2.81, 95% CI 1.59-4.97 for hip fracture). Calibration plots across ATI categories demonstrated deviation from the line of identity in women (calibration slope 2.26 for MOF, 2.83 for hip fracture). An effect of ATI was not seen in men, but this was inconclusive as the sex-interaction terms did not show significant effect modification.CONCLUSION: Greater BMI-discordant abdominal thickness predicted higher risk for fracture when adjusted for FRAX probability, greater in women and younger individuals, with a bimodal effect in diabetes. These data support the need to investigate abdominal thickness as a novel fracture risk factor.

Previous falls are a well-documented risk factor for subsequent fracture but have not yet been incorporated into the FRAX® algorithm.We investigated the association between previous falls and subsequent fracture risk and its relation to sex, age, duration of follow-up, and bone mineral density (BMD) in an international meta-analysis. The resource comprised 891,324 men and women (66.4% female) from 45 prospective cohorts. Previous falls were uniformly defined as any fall occurring during the previous year in 42 cohorts; the remaining three cohorts had a different question construct. During a follow-up of 9,090,849 person-years, 79,953 fractures occurred; 42,805 were hip fractures. Femoral neck BMD was measured in 115,724 individuals. The predictive value of previous falls for incident fracture risk (any fracture, osteoporotic fracture, major osteoporotic fracture, and hip fracture) was investigated using an extension of the Poisson regression model in each cohort and each sex followed by random-effects meta-analyses of the weighted beta coefficients. A previous fall was associated with a significantly increased risk of any fracture both in men (hazard ratio [HR] 1.47, 95% confidence interval [CI] 1.28-1.70) and women (HR 1.39, 95% CI 1.31-1.49) after adjustment for age and duration of follow-up. The HRs were of similar magnitude for osteoporotic, major osteoporotic fracture, and hip fracture. The predictive value was higher in men than women (e.g., for major osteoporotic fracture, HR 1.48 (95% CI 1.23-1.79) in men vs. HR 1.27 (95% CI 1.15-1.40) in women, p for interaction = 0.012) and the HRs associated with previous falls decreased with age in women and with duration of follow-up in men and women for most fracture outcomes. The risk relationship did not materially change when BMD was added to the models and for most fracture outcomes, there was no evidence of an interaction between falls and BMD. Subsequent risk for a major osteoporotic fracture increased 13% and 17% with each additional previous fall in women and men, respectively.In conclusion, a previous self-reported fall confers an increased risk of fracture which seems largely independent of BMD. Previous falls should be considered as an additional risk factor in future iterations of FRAX to improve fracture prediction.

Fracture prediction in patients receiving maintenance dialysis: a simple tool *Andrea Cowan[1], Stephanie Dixon[2], Yuguang Kang[2], Nivethika Jeyakumar[3], Amit Garg[1], Kristin Clemens[4]. [1]Division of Nephrology, Department of Medicine, Western University, Canada. [2]ICES, Canada. [3]Lawson Health Research Institute, Canada. [4]Division of Endocrinology and Metabolism, St Joseph's Hospital, Canada

Purpose: Patients receiving maintenance dialysis are at a 5-fold risk of fracture compared to those with normal renal function, with associated poor outcomes. The Fracture Risk Assessment Tool (FRAX) is validated and commonly used in the general population, but lacks information on its performance in those receiving dialysis. Additionally, FRAX does not account for kidney disease specific risk factors including hyperparathyroidism. The 10-year risk predicted by FRAX may also be less meaningful to those receiving dialysis, where the 5-year survival rate is 53%. We sought to create an easy-to-use, short-term fracture risk prediction tool for both clinical and research applications. Methods: Using linked healthcare databases, we conducted a population-based cohort study of adults aged 40-90 years receiving maintenance dialysis with an available parathyroid hormone (PTH) value in Ontario, Canada between January 1, 2010 and September 30, 2017. Patients were followed for 3 years or until death, fracture, or emigration from the province. We developed a prediction model using routinely collected data including patient demographics, comorbidities and laboratory values using Fine and Gray's subdistribution hazards model to account for the competing risk of death. Models were compared using measures of discrimination, calibration and model fit. Models were internally validated using cross-validation. Results: We identified 11,599 individuals receiving dialysis with an average age of 66; 39% were female and 12% had a previous fracture. 839 fractures were observed within 3 years, 44% of which were in the first year, with hip fracture being the most common (299/839). The final fracture prediction model included age, sex, previous fracture, current steroid use, proton pump inhibitor use, calcitriol use, length of time receiving dialysis, and the concentrations of PTH and serum albumin. The c-statistics (equivalent to the area under the receiver operating curve) for 1-year and 3- year fracture prediction were 0.80 and 0.72 respectively indicating good discrimination. Discussion: Our easily implementable fracture risk score in patients receiving maintenance hemodialysis performs well 1 year and 3 -years without requiring bone density measurement or any extra testing or medical visits. Our short-term risk prediction tool will be helpful in identifying those at highest risk of fracture who would benefit from intervention, or inclusion in future clinical trials.

Active Learning for the Efficient Annotation of Unlabeled Lateral Spine Images Acquired at Baseline from the Canadian Longitudinal Study on Aging *Barret Monchka[1], John Schousboe[2], J Michael Davidson[1], Douglas Kimelman[1], Didier Hans[3], Olivier Lamy[4], Parminder Raina[5], William Leslie[1]. [1]University of Manitoba, Canada. [2]Park Nicollet Clinic HealthPartners Institute University of Minnesota, . [3]Lausanne University Hospital & University of Lausanne, Switzerland. [4]University Hospital, Switzerland. [5]McMaster University, Canada

BACKGROUND: The Canadian Longitudinal Study on Aging (CLSA) acquired 28,657 vertebral fracture assessment (VFA) images during baseline data collection (2011-2015), but the VFAs had not been previously reviewed by medical experts for presence of vertebral fractures (VFs). Convolutional neural networks (CNNs) are deep learning models that can be used within an active learning (AL) framework to identify the most likely positive cases for expert review.AIM: To use an AL approach to efficiently annotate CLSA baseline VFAs with VF status for use in future research.METHODS: CLSA baseline VFAs were randomly divided into two sets: 60% for initial model development, and 40% for model evaluation and refinement. Six iterations of AL selective sampling were used to annotate 3,032 VFAs from the development set and incrementally improve CNN classification performance. Two ensemble models were constructed using the maximum and mean predicted probabilities of VF from separately trained CNNs. In a seventh AL iteration, the mean ensemble was used to select all VFAs from the 40% sample with predicted probability of VF >= 0.1 (n=725), which were annotated and used to estimate model performance. In the final AL iteration, all previously unlabeled VFAs with predicted probability of VF >= 0.1 (n=249) were annotated and used for model training. Improved ensembles were constructed by re-training on all annotated CLSA VFAs (n=3,891) and subsequently used to estimate the probability of VF for the remaining unlabeled images. VFAs were adjudicated and graded by three expert readers using the modified algorithm-based qualitative (mABQ) method. RESULTS: Through AL selective sampling, 4,006 VFAs were selected for expert review: 115 were excluded due to unevaluable levels or VF uncertainty, and 789 VFs were identified for an estimated prevalence of 2.8% (Grade 2-3 prevalence: 1.7%). CNN performance was assessed after six iterations of AL in 710 patients with VF present in 281 (39.6%). The mean ensemble model achieved high overall balanced accuracy (84.4%) against CLSA VFAs, including when stratified by age (range 81.2% to 88.3%) and sex (males 82.5%, females 85.9%) (Table).CONCLUSIONS: AL is an efficient technique to annotate medical images acquired in longitudinal studies and estimate prevalence from unlabeled data. Researchers using our predictions can select classification cut-offs based on their research objectives in order to prioritize case certainty versus case sensitivity.

A Polygenic Risk Score Linked to Fracture Reduction in Adults is Associated with Fracture Reduction in a Multi-Ancestry Sample of Children *Jonathan Mitchell[1], Jonathan Bradfield[2], Shana McCormack[2], Alessandra Chesi[3], Heidi Kalkwarf[4], Dana Duren[5], John Shepherd[6], Kurt Hankenson[7], Andrea Kelly[2], Hakon Hakonarson[2], Struan Grant[8], Babette Zemel[9]. [1]Children's Hospital of Philadelphia, United States. [2]CHOP, United States. [3]Penn, United States. [4]Cincinnati Children's Hospital Medical Center, United States. [5]University of Missouri, United States. [6]University of Hawaii, United States. [7]University of Michigan, United States. [8]Children s Hospital of Philadelphia / University of Pennsylvania, United States. [9]Children s Hospital of Philadelphia, United States

A polygenic risk score, "genetic quantitative ultrasound speed of sound (gSOS)", has been developed using data from adults of European ancestry and is associated with reduced odds of fracture in adults. We aimed to determine if gSOS was associated with the likelihood of having a fracture in a multi-ancestry sample of children.Data from the Children's Hospital of Philadelphia's Center for Applied Genomics were analyzed (N=10,301). Fracture data at the following sites were extracted from electronic health records (EHR): femur, humerus, metacarpal, metatarsal, neck of femur, patella, pelvis, radius/ulna, ribs, scaphoid, tarsal, tibia/fibula and tibia. A total of 21,716 genetic variants were used to calculate gSOS for each participant. Logistic regression models tested for associations between gSOS and the following fracture related outcomes: binary fracture (none or >=1) and fracture location (none, upper limb only, lower limb only, or upper & lower limb). All analyses were adjusted for ancestry and sex differences were assessed using interactions between gSOS and sex (male or female).The sample was comprised of 9,242 (89.7%) children with no history of fracture in their EHR. Of the children with a record of fracture: 581 (5.6%) had 1 recorded fracture, 344 (3.3%) had 2 recorded fractures and 134 (1.3%) had >=3 recorded fractures. Further, 609 (5.9%) had >=1 recorded upper limb fracture, 357 (53.5%) had >=1 recorded lower limb fracture, and 93 (0.9%) had >=1 recorded upper and lower limb fracture. A 1 standard deviation increase in gSOS was associated with reduced odds of having a record of any fracture (OR=0.88, 95% CI: 0.82, 0.94). When considering fracture location, a 1 standard deviation increase in gSOS was associated with reduced odds of having a recorded of upper limb fracture (OR=0.83, 95% CI: 0.75, 0.91). These associations were consistent for both male and female sex.Consistent with the adult literature, and our prior report of gSOS being associated with higher bone mineral density in childhood, a higher gSOS score was associated with reduced odds of having a recorded fracture in childhood. It is therefore likely that having a higher gSOS is a strong genetic marker for enhanced bone accretion in early life that offsets risk for fracture across the lifespan.

Total Body Bone Mineral Content Trajectories from 8 to 40 years of age: A SITAR Nonlinear Growth Model. *Adam Baxter-Jones[1], Ahmed Elhakeem[2], Stefan Jackowski[3], Erin Barbour-Tuck[1], Marta Erlandson[1]. [1]University of Saskatchewan, Canada. [2]University of Bristol, United Kingdom. [3]Chilrden's Hospital of Eastern Ontario Research Institute, Canada

Introduction: Appropriately modelling repeated measures in cohort studies can improve the understanding of the nonlinear development of Bone Mineral Content across the life-course. Growth-related processes of interest include mean trajectories over time, rates of growth at different ages, timings of peak growth, and variability by sex. One innovative modelling approach is to fit Super Imposition by Translation and Rotation (SITAR) models. SITAR is based on the shape invariant model, which assumes that the study population has a common characteristic curve (fitted as fixed-effects), which by shifting and scaling (by subject-specific random-effects) can be made to fit the form of any individual curve. The aim of this study was to develop velocity curves of BMC development for individuals from 8 to 40. Methods: Data is taken from the Saskatchewan Pediatric Bone Mineral Accrual study (PBMAS). PBMAS is a long running cohort study initiated in 1991 which recruited 251 children aged 8-15 years. Participants underwent up to fifteen annual DXA scans (Hologic QDR-2000, array mode) between 1991 and 2017. 112 males and 127 females in PBMAS with >=1 BMC measure were included in this analysis. SITAR models were fitted with

manually selected knots with number and position informed by the cohort-specific model. All analyses were performed in R version 4.0.2 (R Project for Statistical Computing) and RStudio integrated development environment version 1.3.1 (RStudio Team). Results: Models showed increases in BMC through early life with rapid increases, and emerging sex differences, in adolescence. Age at peak BMC accrual in girls was 12.0 +/- 0.9 yrs with a peak accrual of 260.9 +/- 124.9 (g/yrs), compared to boys whose values were 13.7 +/- 0.9 yrs, peak accrual of 337.6 +/- 71.6 (g/yrs). BMC plateaued in emerging adulthood and started decreasing in the fourth decade of life. Discussion: These models graphically illustrate the nonlinear development of BMC across the life-course and show sex differences in both velocities and distance trajectories. They show peak accrual in adolescence, plateauing in emerging adulthood and the start of bone loss between 30 and 40 years of age. The models described in this paper can be extended to explore associations of early life exposures with trajectories, and associations of trajectories with associated future outcomes. Funding: Canadian Institute of Health Research, Canadian Foundation for Innovation, and Saskatchewan Health Research Foundation.

Reliable Quantification of Bone Microstructure from HR-pQCT During Growth Requires Density-Independent Segmentation *Andrew Burghardt[1,] Kyla Kent[2,] Jin Long[3,] Ariana Strickland[3,] Tandy Aye[3,] Mary Leonard[4.] [1]University of California, San Francisco, United States, [2]STANFORD MEDICINE, United States, [3]Stanford University School of Medicine, United States, [4]Stanford School of Medicine, United States

Second generation HR-pQCT uses BMD-based thresholds to segment mineralized bone from soft tissues. This approach does not account for variability in tissue density, which is particularly high during periods of rapid growth in children and adolescents. A density-independent fine structure segmentation method based on the Laplace-Hamming (LH) edge-enhancement operator, significantly improves the accuracy of both trabecular and cortical bone structure measures in adults1. Our goal was to document qualitative improvements in segmentation fidelity in pediatric HR-pQCT scans and compare the impact of segmentation differences on age-related trajectories of structure.Two alternative fine structure segmentation functions were applied within the standard second-generation HR-pQCT image analysis pipeline: (a) the standard BMD-threshold binarization scheme; (b) a fixed-threshold binarization of the edge-weighted, intensity-normalized LH filtered image. Each segmentation approach was used to quantify cortical and trabecular structure in distal tibia HR-pQCT scans acquired at 4.0% proximal to the growth plate in a normative pediatric cohort (n=214; age=5-20). Absolute differences between segmentation methods were calculated for each structure outcome by sex and tanner stage.Qualitatively, BMD-threshold binarizations failed to identify significant amounts of cortical porosity, while also not capturing thin trabecular connections, especially in the central medullary space (Fig. 1). The discrepancy for cortical porosity peaked peri-pubertally in girls (p<0.05), while the difference in trabecular BV/TV decreased with growth for both sexes, with the LH method yielding greater BV pre-pubertally, and lesser BV post-pubertally (p<0.0001). LH detected more trabeculae that were increasingly thinner in boys, compared to BMD-based segmentations (p < 0.01).The standard BMD-based threshold systematically underestimates the quantification of cortical porosity in second-generation HR-pQCT of pediatric subjects. This error is most profound during puberty. Additionally, central medullary trabeculae are often lost by the BMD-based segmentation but rescued by the LH approach. Therefore, fine structure segmentation methods that are independent of BMD are essential to accurately capture age-wise trajectories in bone micro-structure during growth.1. Sadoughi S, et al. A Laplace-Hamming Binarization Approach for Second-Generation HR-pQCT Rescues Fine Feature Segmentation. JBMR 2023

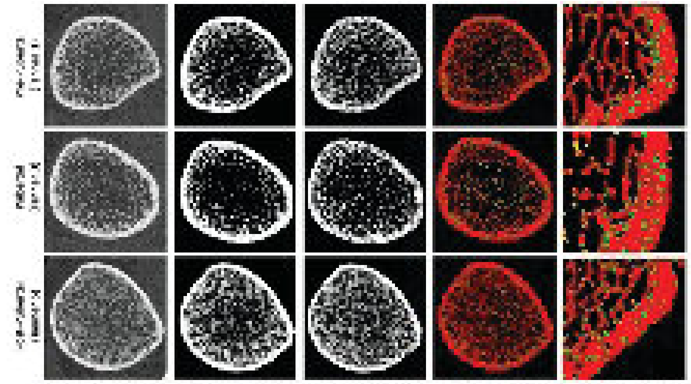

Fig. 1 Representative distal tibia HR-pQCT slices from pre- (top), peri- (center) and pubertal (lower) participants, illustrating fine-structure segmentations using the standard BMD threshold binarization (second column) or Laplace-Hamming binarization (third column), and difference image (last two columns; red = missing; green = overestimated by BMD-based binarization; yellow = rescued by LH-based binarization).

A young-child formula with the synbiotic l reuteri and galacto-oligosaccharides increases bone strength in toddlers: a 6-month randomized Controlled Trial *Nicolas Bonnet[1,] Maria Rosario Capeding[2,] Marc Garcia Garcera[3,] Laura-Florina Kratinger[4,] Jowena Lebumfacil[5,] Lhodie Phee[2,] Ivana Jankovic[6,] Yipu Chen[6,] Delphine Egli[6,] Marie-Noëlle Horcajada[3.] [1]Nestlé research, Switzerland, [2]Clinical Research Unit, Asian Foundation for Tropical Medicine, Inc. (AFTMI), Muntinlupa City, Philippines, Philippines, [3]Nestlé Institute of Health Sciences/ Nestlé Research, Lausanne, Switzerland, Switzerland, [4]Clinical Research Unit, Nestlé Research, Lausanne, Switzerland, Switzerland, [5]Wyeth Nutrition, Makati City, Philippines, Philippines, [6]Nestlé Product Technology Center - Nutrition, Société des Produits Nestlé S.A., Vevey, Switzerland, Switzerland

Toddlerhood is a critical period for bone mass acquisition. This study evaluated the impact of consuming a young child formula containing a synbiotic composed of Limosilactobacillus (L., previously Lactobacillus) reuteri + galacto-oligosaccharides (GOS) on bone quality in healthy young children.In this randomized, double-blind controlled clinical trial performed in the Philippines, children aged 2-3 years received for 6 months a young child formula containing L. reuteri DSM 17938 (at concentration that guarantees 10exp8 cfu/day) + GOS (4g/L) (Experimental Young Child Formula with synbiotic, EYCF, n=91) or a minimally fortified powdered milk mimicking local traditional milks (control milk, CM, n=91). Children were advised to consume 2 servings/day. The tibia quality was assessed at baseline and after 3- and 6-months measuring speed of sound by ultrasound. A linear mixed model with repeated measurements was applied with fixed effects for treatment group, gender, visit, visit x treatment interaction, and baseline values for speed of sound, vitamin D levels in blood and body mass index. Blood bone turnover markers (CTX and P1NP) as well as microbiome composition and function were performed at all timepoints, respectively by ELISA and shotgun metagenomics.Mean age at baseline was 29.6 +/- 3.6 months and 53% were female. The primary outcome, tibia speed of sound measured at 6 months was significantly higher in EYCF compared to CM. The estimated average difference was 58.91 [95% CI = (21.34, 96.48) m/s], p=0.002, in the full analysis set, supported by estimated effect on the per protocol population (p=0.005). A positive effect was already observed after 3 months of intervention 53.00 [95% CI = (7.05, 98.95) m/s] p=0.024. Bone turnover index (CTX/P1NP) was 25% higher in EYCF vs CM [95% CI = (1, 49) %], p=0.041. Microbiome beta diversity analyses based on principal coordinate analysis could differentiate the EYCF samples from CM (p<0.001). L. reuteri abundancy was 15-fold higher in EYCF vs CM (p<0.0001) and a prevalence increase of 7-fold (p<0.0004).Consumption of a young child formula containing the synbiotic L. reuteri + GOS promotes bone strength improving bone quality by increased bone turnover, and induces microbiome changes supporting bone quality improvement in healthy young children.

Fracture risk, bone mineral density and bone biochemistry: a phase 3, double-blind, placebo-controlled randomized trial of vitamin D supplementation in schoolchildren *Davaasambuu Ganmaa[1], Uyanga Buyanjargal[2], Polyna Khudyakov[3], Adrian Martineau[4]. [1]Channing Division Network of Medicine, Brigham and Women Hospital, Harvard Medical School and Harvard T.H. Chan School of Public Health, Boston, USA, United States. [2]Mongolian Health Initiative, Mongolia. [3]Sage Therapeutics, United States. [4]Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, United Kingdom

Background:There are numerous observational studies reporting associations between vitamin D deficiency and increased risk of fracture and low bone mineral density (BMD) in children. We previously reported a very high prevalence of vitamin D deficiency in Mongolian schoolchildren living in Ulaanbaatar, the coldest capital in the world. We conducted a phase 3 randomized controlled trial to determine whether a 3-year course of oral vitamin D supplementation influences BMD or fracture risk in this population.ObjectiveTo determine the effects of vitamin D supplementation at a dose of 14,000 IU per week in all participants: (i) fracture incidence (n=8,851), and in a sub-set of participants: (ii) calcaneal bone mineral density (n=1,465) and (iii) serum concentrations of 25-hydroxyvitamin D (25[OH]D) (all participants), parathyroid hormone (PTH), calcium, total alkaline phosphatase (ALP) and bone-specific alkaline phosphatase (BSAP) (n=100 of BMD sub-study) at baseline and 3-year follow-up.MethodsA phase 3 randomized, double-blind, placebo-controlled trial in which 8,851 children were given 14,000 IU/week vitamin D3 supplement or placebo for 3 years. Analyses were conducted for all efficacy outcomes to determine whether the effect of the intervention varied according to baseline 25(OH)D D levels (<10 vs. >=10 ng/mL), calcium intake (<500 vs. >=500 mg/day), and baseline calcaneal BMD z-scores (<-2.00 vs. >=-2.00).ResultsAt baseline 95.6% of participants had vitamin D deficiency (25[OH] D <20 ng/mL) with mean serum 25(OH)D concentration 11.9 ng/mL. The intervention was effective in correcting vitamin D deficiency: end-trial 25(OH)D levels were >=20 ng/mL in 89.8% of participants randomized to vitamin D vs. 5.6% of those randomized to placebo (P<0.001), and this was associated with suppression of PTH concentrations (mean difference -13.6 pmol/L, 95% CI -23.5 to -3.7). However, there was no difference in the proportion of participants randomized to vitamin D vs. placebo reporting at least one fracture (268/4176 [6.4%] vs. 253/4172 [6.1%], respectively; adjusted risk ratio 1.10, 95% CI 0.93 to 1.29, P=0.27) or in mean calcaneal BMD z-score (adjusted mean difference between arms -0.06, 95% CI -0.18 to 0.07, P=0.36).Effects of the intervention on serum BSAP concentrations were modified by baseline 25(OH)D concentration (P for interaction = 0.04) but effects on fracture risk and calcaneal BMD were not (P values for interaction >=0.67).ConclusionsIn a population of children with low baseline vitamin D status, this RCT found that 14,000 IU weekly vitamin D3 supplementation was effective in rendering adequate vitamin D status and suppressing PTH concentrations but it did not affect risk of fracture or calcaneal BMD.

Bone-Derived PDGF-BB Drives Brain Vascular Calcification During Aging *Jiekang wang[1], Ching-lien Fang[2], Mei Wan[2], Surendra Kumar[4], ke shen[2], huixin hao[2], kangping song[2], Xu Cao[4]. [1]johns hopkins university, . [2]Orthopedic Surgery, United States. [4]Johns Hopkins University, . [4]Johns Hopkins University, United States

Vascular calcification and osteoporosis often coexist in the aging population. While the pathogenesis of large vessel calcifications has been intensively studied, little is known on the mechanisms of microvascular calcification in brain. In fact, brain calcification is a prevalent age-related pathology, affecting over 20% of the elderly population and frequently co-occurring with neuroinflammatory conditions. The present study aims to define the role of bone-derived cues in the pathogenesis of brain microvascular calcification.Using various approaches, including whole-brain micro-CT scanning, susceptibility-weighted imaging (SWI)-based MRI screening, and histological/immunofluorescence analyses, we consistently detected a high incidence of brain calcification nodules in 18- to 24-month-old mice, ranging from 71.4% to 80.9%. The calcification nodules primarily occur in the thalamus regions in aged mice but not in young mice. We recently reported that with aging, preosteoclasts in bone produce higher levels of platelet-derived growth factor-BB (PDGF-BB), which can then enter the bloodstream and cross the blood-brain barrier to regulate brain cell activity. We examined whether bone-derived PDGF-BB is also involved in the development of brain calcification using conditional Pdgfb transgenic (PdgfbcTG) and knockout (PdgfbcKO) mouse models. Young PdgfbcTG mice, in which Pdgfb is overexpressed in preosteoclasts, have much higher serum level of PDGF-BB and recapitulate the thalamic calcification phenotype in aged mice. Conversely, old PdgfbcKO mice, in which Pdgfb is deleted selectively in preosteoclasts, have diminished thalamic calcification. To further explore the molecular mechanisms underlying PDGF-BB-induced brain vessel calcification, we developed an ex-vivo cerebrovascular culture system, in which we treated the isolated brain micro-vessels with recombinant PDGF-BB. PDGF-BB directly promoted microvascular calcification. Osteogenic gene array and scRNA-Seq analyses revealed that PDGF-BB upregulates multiple osteogenic differentiation genes and a phosphate transporter Slc20a1 in cerebral micro-vessels. We also found that PDGF-BB activates ERK signaling and its downstream transcription factor RUNX2, which binds to the promoter regions of Slc20a1 for gene transcription. Our results provide new evidence for the bone-vascular interrelationship and uncover ERK-RUNX2-Slc20a1 signaling as important mediators for PDGF-BB-induced micro-vessel calcification.

Gut-bone axis: X/A-like cells may mediate the effects on skeletal homeostasis *Caroline de Carvalho Picoli[1], Jeyrie Ramos Aponte[1], Clifford J. Rosen[1], Ziru Li[1]. [1]MaineHealth Research Institute, United States

Background- Bariatric surgery is the most effective treatment for severe obesity and type 2 diabetes. However, this procedure causes various side effects, such as bone loss and increased fracture risks. While changes in gut hormones and microbiota were considered as potential mechanisms, the contribution of the major surgical site (the stomach) has been largely overlooked. X/A-like cells account for ~20% of the endocrine cell in the stomach and produce ghrelin. Vertical sleeve gastrectomy (VSG), the most popular bariatric surgical procedure, reduces ghrelin in humans and rodents. We are sought to understand the roles of X/A-like cells in VSG-caused bone loss. Methods- Firstly, we employed a hand-sewing VSG mouse model. C57BL/6J male mice were fed a HFD for 8 weeks and then underwent VSG. A subgroup of mice received ghrelin supplementation. Secondly, we utilized an inducible X/A-like cell-depletion mouse model. We bred ghrelin (Ghrl)-Cre mice with diphtheria toxin receptor (DTR) mice, which allowed for specific deletion of X/A-like cells following DT injections. Changes in fat mass, glucose and bone were evaluated 4 weeks after VSG or DT treatment. Results- VSG resulted in a significant reduction in fat mass and improvement in glucose metabolism, but it also caused trabecular and cortical bone loss. Interestingly, the supplementation of exogenous ghrelin did not impact these effects, suggesting that ghrelin may not be the critical endocrine factor mediating the effects of VSG on metabolic benefits and skeletal complications. Furthermore, we observed a substantial loss of X/A-like cells following VSG. To further validate the importance of X/A-like cells in the whole-body and bone metabolism, we employed Ghrl-DTR mice treated with DT, resulting in approximately 93% reduction in X/A-like cell numbers. This reduction was associated with a significant improvement in glucose metabolism but also caused trabecular bone loss. The similarity of the effects seen in X/A-like cell depletion with those observed in VSG suggests that these cells may mediate the effects of VSG on glucose and bone metabolism. Conclusions- Our VSG mouse model replicated the metabolic benefits and skeletal complications observed in clinical patients. Ghrelin was not found to be a significant contributor to VSG-induced glucose improvement and skeletal complications. Our findings highlight the significant role of X/A-like cells in skeletal homeostasis through the secretion of unknown factors.

Eldecalcitol Prevents Muscle Loss and Osteoporosis in Disuse Muscle Atrophy via NF-?B Signaling in Mice *Haichao Zhang[1], Zheng Ke[2], Shuangshuang Dong[2], Yanping Du[1], Wenjing Tang[1], Minmin Chen[1], Weijia Yu[1], Qun Cheng[1]. [1]Department of Osteoporosis and Bone Disease, Huadong Hospital Affiliated of Fudan University, Research Section of Geriatric Metabolic Bone Disease, Shanghai Geriatric Institute, Shanghai, 201100, PR China , China. [2]Medical Division, Chugai Pharma China Co., Ltd., Shanghai, 200021, PR China, China

IntroductionWe investigated the effect of eldecalcitol (ELD) on disuse muscle atrophy and its molecular mechanisms.MethodTail suspension (TS) was used to mimic disuse muscle atrophy in 6 weeks old C57BL/6J male mice which were randomly assigned to control, TS, and TS-ELD-treated groups (3.5/5 ng) and were injected intraperitoneally twice a week for 3 weeks. Grip strength and gastrocnemius (GAS), tibialis anterior (TA), and soleus (SOL) muscle weights were determined. Oxidative stress was evaluated by malondialdehyde, superoxide dismutase, glutathione peroxidase, and catalase. Bone microarchitecture was analyzed using microcomputed tomography. Effect of ELD on MHC and Atrogin-1 and MuRF-1 of C2C12 myoblasts was assessed by immunofluorescence. ELD influence on NF-?B signaling pathway and vitamin D receptor (VDR) was assessed via immunofluorescence, (co)-immunoprecipitation, and VDR knockdown studies.ResultsELD increased grip strength (P<0.01) and restored TS-induced muscle loss in GAS, TA, and SOL (P<0.05 to P<0.001). Bone mineral density (BMD) and bone architecture was improved in the ELD group by reducing bone loss. Cortical and trabecular BMD of the distal femur were significantly decreased by 12.37% and 28.51%, respectively, which reversed upon ELD administration. Decreased bone surface/total tissue volume (BS/TV) (62.56%), trabecular number (Tb.N) (65.92%), trabecular thickness (Tb.Th) (26.11%) in the TS group as compared to control group (P<0.001). However, their levels were partly restored by 78.22%, 85.68%, and 19.04%, respectively, in the ELD low-dose group (3.5 ng/week). Antioxidant defense system of GAS muscle and serum was altered in the TS group as indicated by the lower levels of SOD, GSH-Px, and CAT in serum (39.04%, 40.53%, and 41.93%, respectively) and in GAS muscle (51.38%, 42.48%, and 50.31%, respectively). In differentiated C2C12 myotubes, the addition of TNF-? elevated the levels of Atrogin-1 and MuRF-1 and decreased the levels of MHC compared with the control cells. ELD inhibited TNF-?-induced myotube atrophy in a concentration-dependent manner. ELD (10 nM) significantly inhibited the expression of MuRF-1 by 38.79% (P<0.001) and Atrogin-1 by 41.52% (P<0.01), increased the diameter of

myotubes (P<0.05), and inhibited the expression of P65 and P52 components of NF-?B and P65 nuclear location, thereby inhibiting NF-?B signaling.ConclusionsELD was beneficial against disuse-induced muscle atrophy via NF-?B inhibition.

FGF23 Neutralizing Antibody Ameliorates Abnormal Renal Phosphate Handing in Sickle Cell Disease Mice *Liping Xiao[1], Kai Clarke[1], Marja Marie Hurley[2]. [1]UConn Health, United States. [2]UCONN Health School of Medicine, United States

The mechanisms responsible for the abnormal serum phosphate level in patients with sickle cell disease (SCD) and preserved glomerular filtration rate are not fully understood. Fibroblast growth factor 23 (FGF23), a bone-derived phosphaturic hormone is up regulated by iron deficiency, hypoxia, and high erythropoietin (EPO), which are seen in SCD. In this study, we assessed the involvement of FGF23 signaling pathway in the impaired renal phosphorus handling in kidneys of SCD mice. Six months old healthy control (Ctrl) and Townes SCD mice were subcutaneously injected with control IgG or rat monoclonal anti-FGF23 neutralizing antibody (FGF23Ab, kindly provided by Amgen) at 10mg/kg body weight. Then the mice were housed in metabolic cages. Twenty-four hours later the mice were euthanized for sample collection. Serum biochemistry revealed no differences in creatinine between Ctrl versus SCD mice. Serum intact FGF23 level was higher in SCD-IgG compared with Ctrl-IgG in female, FGF23Ab significantly decreased serum intact FGF23 level in both male and female (Fig. 1A). Although there was no difference in serum Pi between Ctrl-IgG and SCD-IgG urine phosphate/creatinine (Pi/Cr) was significantly higher in SCD-IgG group compared with Ctrl-IgG in both male and female, which was rescued by FGF23Ab treatment (Fig.1B). Analysis of kidneys by Western blot showed that pFGFR1 was significantly higher in SCD-IgG compared with Ctrl-IgG male, which was rescued with FGF23Ab treatment. pFGFR2 and pFGFR4 were significantly higher in SCD-IgG compared with Ctrl-IgG in both male and female, FGF23Ab treatment did not alter pFGFR2 and pFGFR4 expression level. There was no difference in pFGFR3 expression between Ctrl-IgG and SCD-IgG, FGF23Ab treatment significantly decreased pFGFR3 level in SCD kidney. Immunohistochemistry (IHC) staining showed that there was increased phospho p44/42 MAPK (Erk1/2) (pERK), phospho Janus Activating Kinase 3 (pJAK3), and phospho serum glucocorticoid-inducible kinase 1 (pSGK1) in SCD-IgG kidney compared with Ctrl-IgG, which were partially rescued with FGF23Ab treatment (Fig.1C). A significant reduction in the phosphate transporter sodium-phosphate cotransporter NaPi-2a (Npt2a) protein was observed in SCD-IgG kidneys, which was increased by FGF23Ab treatment (Fig.1D). We conclude that FGF23/FGFR1 promotes phosphate wasting in SCD by downregulating expression of the NPT2a via modulation of ERK1/2, JAK3, and SGK1 signaling.

Implicating peripheral neural mediated MAPK signaling in obesity induced alterations in bone mass *Masnsen Cherief[2], Mario Gomez-Salazar[2], Minjung Kang[2], Mingxin Xu[2], Sowmya Ramesh[2], QIZHI QIN[2], Mary Archer[2], SEUNGYONG LEE[3], Thomas Clemens[4], Ahmet Hoke[2], Aaron James[2]. [2]Johns Hopkins University, United States. [2]Johns Hopkins University, . [3]Midwestern University, Republic of Korea. [4]University of Maryland, Baltimore, United States

Introduction: Recent research suggested that high fat diet (HFD)-associated polyneuropathy may contribute to low bone mass. Here, we show that bone loss induced by HFD was concomitant with a blunted periosteal innervation. Transcriptomic analysis showed a reduced proliferation and differentiation potency in HFD periosteal mesenchymal progenitor cells (pMSCs), associated with reductions in MAPK signaling. Finally, we queried if neural conditioned media (CM) could rescue the proliferation and differentiation abilities of HFD pMSCs. Methods: JHU ACUC approved our experiments. HFD or normal diet (ND) was instituted from 4 to 16 weeks of mice age. µCT was used to quantify cortical and trabecular bone parameters. Skeletal innervation was assessed by the neuronal markers TUBB3. For scRNA-Seq, femur periosteum was digested and sorted to exclude erythrocytes. For pMSCs proliferation and differentiation assays, cells were seeded for further analysis. Results: We demonstrated that HFD led to expected trabecular and cortical bone structural deficits (Fig. 1A-D). In addition, HFD led to a pronounced reduction in skeletal nerve density within the femoral periosteum (Fig. 1E-F). This is the first report of a skeletal neuropathy in any experimental model of diabetes. Next, pMSCs cells were subclustered into MSC progenitors, Pre-osteoblasts, and Osteoblasts (Fig. 2A). Transcriptomics revealed a reduction in 'proliferation' indices, MAPK, WNT and TGFb signaling activity among pMSCs of HFD mice (Fig. 2B). Finaly, HFD reduced proliferation and osteogenic differentiation potential of pMSCs, corroborating our transcriptional data. Next, we exposed pMSCs to dorsal root ganglia (DRG) CM and assessed their response to neural-derived paracrine factors (Fig. 3). DRG CM significantly enhanced the differentiation and proliferation of ND mice pMSCs. Remarkably, DRG CM rescued the proliferaton and osteogenic differentiation potential of HFD pMSCs (Fig. 3A-B). This highlights the potential relationships between skeletal polyneuropathy and defective skeletal progenitor cell function. Conclusion: Metabolic skeletal polyneuropathy is associated with bone architectural deficits and reduced proliferation and osteogenic differentiation in pMSCs, suggesting a direct impact of diabetic neuropathy on bone health. Exposure to physiological neural input has the potential to restore bone health in obesity related bone disease.

[10]RIKEN, Center for Integrative Medical Science, Japan

Adolescent idiopathic scoliosis (AIS) is a common and progressive spinal deformity that exhibits striking sexual dimorphism, with girls at more than five-fold greater risk of severe disease compared to boys. Despite its medical significance, insights into the pathogenesis of AIS are just emerging. By genome-wide association and functional studies we previously defined a female-specific AIS risk locus in an enhancer near the PAX1 gene. Here, we sought to define the roles of PAX1 and newly-identified AIS-associated genes in the mechanism of AIS. In a discovery and follow-up meta-analysis association study of nonsynonymous variants within extracellular matrix (ECM) genes (total N=103,757 individuals), we identified significant associations with a variant in COL11A1 (rs3753841; p.(Pro1335Leu); P=7.07e-11, OR=1.118). Using CRISPR mutagenesis we generated Pax1 knockout mice (Pax1-/-), which were viable and displayed a kinked tail phenotype. By RT-PCR in tails of E12.5 Pax1-/- mice, we found reduced expression of AIS-associated genes including Col11a1. Immunofluorescence microscopy in postnatal spines detected overlapping staining of Pax1 and Col11a1 at the cartilaginous endplate-osseous junction encompassing the vertebral growth plate, with reduced expression of Col11a1 in Pax1-/- spines compared to wildtype. To study the role of Col11a1 in growth plate cells (GPCs), primary rib cartilage from Col11a1fl/fl mice was cultured in the presence or absence of Cre-expressing adenovirus. By RT-PCR in these cells, we observed significant upregulation (P<.05) of Mmp3, encoding the matrix metalloproteinase 3 “stromolysin” enzyme that is known to be regulated by Col11a1 in solid tumors. Conversely, endogenous Mmp3 expression was significantly downregulated after lentiviral overexpression of the human COL11A1WT, but not COL11A1P1335L, in Cre-expressing Col11a1fl/fl SV40-immortalized GPCs. These results support negative regulation of Mmp3 expression by Col11a1 that is abrogated by the AIS-associated COL11A1P1335L variant in GPCs. Col11a1 is regulated by estrogen receptor beta (ESR2) in ovarian cells. siRNA-mediated Esr2 knockdown in mouse GPCs significantly increased Col11a1 expression, and significantly decreased Mmp3 expression, as did tamoxifen treatment of these cells. These studies support a new model wherein genetic variation and estrogen signaling increase susceptibility to spinal deformity during adolescent growth via a Pax1-Col11a1-Mmp3 signaling axis.

TYRA-300 Demonstrates Significant Increases in Growth and Bone Length in a Mouse Model of FGFR3-Related Skeletal Dysplasia *Laurence Legeai-Mallet[1], Matthias Guillo[1], Nabil Kaci[1], Jacqueline H. Starrett[2], Ronald V. Swanson[2]. [1]Université de Paris Cité, Imagine Institute, Laboratory of Molecular and Physiopathological Bases of Osteochondrodysplasia. INSERM UMR1163, France. [2]Tyra Biosciences, United States

Achondroplasia (ACH) is the most common human skeletal dysplasia affecting ~1 in 25,000 births. Infants with ACH have an increased risk for death related to critical foramen magnum stenosis leading to cervicomedullary compression. A specific mutation in FGFR3, G380R, causes over 99% of achondroplasia. FGFR3 is expressed in growth plate chondrocytes where it functions to slow endochondral bone formation. The G380R mutation, as well as other activating mutations, results in increased FGFR3 activity, which suppresses chondrogenesis in the growth plate, disturbing long bone elongation. Vosoritide, a C-naturetic peptide analogue, acting exclusively on the MAP kinase pathway, was recently approved as a daily injection to increase annual growth velocity in children with open growth plates. While an important breakthrough, long-term effects on ACH-associated comorbidities are not yet known. TYRA-300 is an oral, highly selective FGFR3 inhibitor currently undergoing a Phase 1/2 clinical trial, SURF301 (Study in Untreated and Resistant FGFR3+ Advanced Solid Tumors). To explore the effectiveness of TYRA-300 in FGFR3-related skeletal dysplasias, TYRA-300 was evaluated in an FGFR3Y367C/+ transgenic mouse model. TYRA-300 administered daily at a 1.2 mg/kg dose for 15 days in the FGFR3Y367C/+ mouse model significantly increased body length in mice by 17.6% compared to the vehicle (Figure 1, p<0.0001) and increased the length of the femur (+24.4%), tibia (+38.3%) and L4-L6 (+23.9%) in mice (p<0.0001). Growth in the skull resulting in elongation (+11.0%) and improvement in the size and shape of the foramen magnum were also observed. Histological staining of the femurs revealed restoration of the hypertrophic zone and secondary ossification center within the epiphysis after TYRA-300 treatment. Collagen X staining also indicated that TYRA-300 improved the structure of the trabecular bone and increased chondrocyte differentiation. These data indicate that inhibiting FGFR3 directly leads to highly increased bone length, as well as foramen magnum diameter, in this preclinical model.

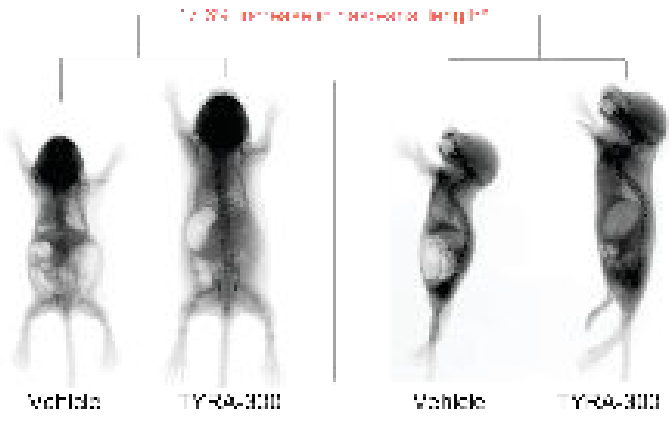

Figure 1. Representative whole body X-ray of vehicle treated heterozygous [illegible] mouse on the left and TYRA-300 treated heterozygous [illegible] mouse on the right. Treatment consisted of daily oral gavage injection of TYRA-300 at 1.2 mg/kg for 15 days starting at day 1 after birth. [illegible] p<0.0001

Conditional Deletion of Runx2 in Cranial Base Chondrocytes Causes Midfacial Hypoplasia *Noriaki Ono[1], RENNY FRANCESCHI[4], Wanida Ono[1], Ariel Arbiv[5], Annabelle Zhou[5], LENA BATOON[4], Ashley Dixon[5], José Brenes[5], SHAWN HALLETT[5]. [1]University of Texas Health Science Center at Houston School of Dentistry, United States. [4]University of Michigan, United States. [5]University of Michigan School of Dentistry, United States. [4]University of Michigan, . [5]University of Michigan School of Dentistry,

The cranial base growth center synchondroses regulate anteroposterior craniofacial growth. Like the long bone growth plate, the synchondrosis is comprised of distinct layers of chondrocytes, but is organized in an opposite-facing mirror-like fashion, facilitating bidirectional cranial base growth. In humans and mice, overactivation of fibroblast growth factor receptor 3 (FGFR3) signaling causes achondroplasia associated with premature fusion of the synchondrosis, while RUNX2 haploinsufficiency causes cleidocranial dysplasia (CCD) with midfacial hypoplasia. Runx2 regulates Fgfr3 expression in vitro; however, signaling mechanisms regulating chondrocytes in the synchondrosis are not well understood. We hypothesize that Runx2 is regulated by FGFR3 signaling and maintains chondrocyte activities in the synchondrosis. To address this, we used a tamoxifen-inducible Fgfr3-creER line and Runx2-floxed alleles to ablate Runx2 in Fgfr3+ chondrocytes. Control, Runx2cHet (Fgfr3-creER; Runx2fl/+) and Runx2cKO (Fgfr3-creER; Runx2fl/fl) mice carrying R26R-tdTomato and Col1a1-GFP reporters were pulsed with tamoxifen at P3 and chased to sequential timepoints. Morphometric analyses of the skull were completed by 3D microCT analyses. EdU labeling and TUNEL assays were conducted to evaluate cell proliferation and apoptosis, respectively. Sections were stained with Safranin-O and TRAP to visualize cartilage matrix and osteoclasts, respectively. Runx2cKO mice showed anteroposteriorly shortened skulls accompanied by synchondroses lacking distinctive chondrocyte layers that prematurely ossified associated with tdTomatoneg/Col1a1-GFP+ osteoblasts in the center of the synchondrosis. Chondrocyte proliferation and apoptosis were both decreased, while TRAP+ osteoclasts were increased, in Runx2cKO synchondroses. Expression of ColX and Fgfr3 were upregulated in Runx2cKO synchondrosis, demonstrating that Runx2 may be a negative regulator of chondrocyte hypertrophy and FGFR3 in the synchondrosis. Therefore, deletion of Runx2 may result in overactivation of Fgfr3 and its subsequent downstream signaling, leading to accelerated chondrocyte hypertrophy, reduced proliferation and precocious ossification of the synchondroses. Our study is the first to demonstrate a possible FGFR3-RUNX2 axis in regulating synchondrosis chondrocytes, and may catalyze the identification of new therapeutic targets to treat midfacial skeletal malformations in humans.

The Role of Salt Inducible Kinases in Alveolar Bone Development *Nicha Tokavanich[1], Katelyn Strauss[5], Christian Castro[5], Marc Foretz[3], Wanida Ono[4], Marc Wein[5]. [1]Massachusetts General Hospital, Harvard School of Dental Medicine, United States. [5]Massachusetts General Hospital, United States. [3]University of Paris, Institut Cochin, France. [4]University of Texas Health Science Center at Houston School of Dentistry, United States. [5]Massachusetts General Hospital,

BackgroundAlveolar bone is a specialized part of the jawbones that supports and anchors teeth. It is formed from neural crest mesenchymal cells and regulated by various signaling pathways, including the parathyroid hormone-related protein (PTHrP) pathway. Salt-inducible kinases (SIKs) are key intracellular regulators of PTH/PTHrP signaling in long bones. However, the role of these kinases in jawbone remains unknown.MethodsMice lacking SIK2 and SIK3 were generated using tamoxifen-inducible Ubq-creERt2.Animals were divided into two groups: Sik2f/f ; Sik3f/f (Control) and Ubq-creERt2 ; Sik2f/ f ; Sik3f/f (dKO). Tamoxifen was injected to all mice at P3. Mandibles were collected at P8, P11, P14, P21 and P28. Histology of hemisected mandibles was observed at all time points. Immunohistochemistry, histomorphometry, and micro-CT images at P28 were rendered and analyzed.ResultsSIK2/SIK3 deletion globally at P3 led to small and misshaped mandible without significant difference in tooth eruption. Interestingly, combined ablation of SIK2/SIK3 led to a near complete absence of alveolar bone. Tartrate-resistant acid phosphatase (TRAP) staining revealed fewer osteoclasts in dKO alveolar bone compared to control, and less Calcein labeling was found in dKO mandibles in regions of absent alveolar (inter-radicular and inter-septal) bone. In addition, cells in these regions of dKO mandibles show increased Alkaline Phosphatase and reduced Osteocalcin expression, suggesting arrested osteoblast maturation. Micro CT images showed thicker, but smaller mandibles with increased cortical bone porosity and punched-out lesions surrounding molars.ConclusionConditionally ablated SIK2/SIK3 mandible at P3 causes malformed mandibles with a near complete absence of alveolar bone. Fewer osteoclasts and decreased Calcein labeling suggest that the lack of bone is due to disrupted bone formation. Increased number of immature osteoblasts was seen with decreased mature osteoblasts indicating that the lack of SIK2/SIK3 ablation disrupts the terminal maturation of osteoblasts that produce alveolar bone. Taken together, these data, which contrast with what has been observed to date regarding the role of these kinases in the appendicular skeleton, suggest that SIKs play important roles in osteoblast maturation and differentiation in the alveolar bone.

Nfil3, A Novel PTH Target Involved in Bone development *Omar Al Rifai[1], Rene St-Arnaud[1]. [1]Shriners Hospitals for Children - Canada/ Department of Human Genetics, McGill University - Canada, Canada

Parathyroid hormone (PTH) intermittent administration at low dose promotes bone formation within its osteoanabolic window. It is commonly used for the treatment of osteoporosis; however, its downstream signaling pathway is not fully understood. In our laboratory, we characterized the transcriptional corregulator NACA (alpha chain of the nascent polypeptide-associated complex) as an essential component of the PTH signal transduction cascade that is necessary for its osteoanabolic function, in part by regulating the Bglap and Lrp6 promoters (MCB, 2005; BBA, 2018; IJMS, 2022). ChIP-Seq analysis against NACA identified the Nuclear factor interleukin-3-regulated (Nfil3) as a NACA target induced following PTH treatment depending on NACA availability (Bone, 2020). NFIL3, also known as E4BP4, is a basic domain leucine zipper transcription factor initially characterized as a repressor of gene transcription (MCB, 1992). Little is known about NFIL3's function in bone cells and its role in bone development and PTH signaling was never addressed in vivo. Using molecular biology tools and an animal model, we investigated NFIL3's requirement for bone development ex vivo and in vivo. Our data show that NFIL3 acts as an activator of gene transcription in osteoblasts. ChIP-Seq and RNA-Seq analysis shows that NFIL3 binds to the proximal promoter of osteoblasts differentiation markers such as Alpl, Col1a1, Bglap, Sp7 and Runx2. Nfil3 inactivation in primary osteoblasts decreases the expression of these targets, resulting in decreased mineralization. To assess the function of NFIL3 in vivo, we generated a mouse strain deficient for Nfil3 in osteoblasts and osteocytes (hOC-Cre;Nfil3fl/fl) by breeding Nfil3fl/fl mice with hOC-Cre mice, which express the Cre driver under the control of the human osteocalcin promoter. These mice exhibit a normal trabecular bone phenotype but a reduced cortical bone volume, area, diameter, and thickness as assessed by microcomputed topography. Consistently, three point bending tests and gene expression analysis show a reduction in biomechanical properties of long bones and a decrease in expression of osteoblastic and osteocytic differentiation markers in Nfil3 deficient mice.Our data describe for the first time a role for NFIL3 in bone development in vivo. It demonstrates NFIL3 as a PTH downstream target acting as an activator of gene expression in osteoblasts, supporting a potential role of NFIL3 in PTH signaling in vivo.

Automated immunohistochemistry for TRAcP facilitates osteoclast detection and counting for bone histomorphometry: A validation study *Marie-Josée Bégin[1], Natalie Dion[2], Louis-Georges Ste-Marie[1]. [1]Division of Endocrinology, Department of Medicine, Centre hospitalier de l'Université de Montréal, Université de Montréal, Canada. [2]Department of Pathology, Centre hospitalier de l'Université de Montréal, Université de Montréal, Canada

Histomorphometric analysis of undecalcified bone specimens is the gold standard for diagnosis of complex bone disorders. This analysis requires the measurement of many variables, including osteoclasts (Oc) count per bone perimeter (N.Oc/B.Pm). Oc are identified by their morphology and multinuclearity on Goldner's trichrome stained (GTS) sections. To facilitate Oc count, histological sections are stained by an enzymatic histochemical reaction (EHR) of Tartrate Resistant Acid Phosphatase (TRAcP), an Oc biomarker. This technique has certain limitations including the possible alteration of enzymatic activity by bone tissue preparation with ethanol fixation and methyl methacrylate embedding (EFMMAE). In pathology laboratories, biomarkers such as TRAcP are routinely detected by automated immunohistochemistry technique (AIHC) performed on sections of formalin-fixed and paraffin-embedded (FFPE) of decalcified bone biopsies. We aim to validate the use TRAcP detection by AIHC on sections of undecalcified bone tissue EFMMAE in order to improve Oc identification and counting. To this end, transiliac bone biopsies from 20 adult patients (68.7 +/- 8.7 yo) affected by various metabolic bone diseases were studied. AIHC was performed with a Ventana BenchMark ULTRA system (Roche-Diagnosis) using mouse monoclonal antibody for TRAcP (clone 9C5) on deplastified sections with a protocol usually used for FFPE tissue. Osteoclastic detection by AIHC was confirmed by GTS on consecutive sections (Figure 1), as well as with EHR TRAcP and with AIHC Cathepsin K. The AIHC TRAcP showed a strong positive correlation with N.Oc/B.Pm measurements on GTS (r=0.90), as well as with bone formation rate per bone surface (BFR/BS) (r=0.84). Interestingly, there was a significantly greater detection of Oc with AIHC than with GTS (p<0.001). Furthermore, the difference in Oc counts between the two methods was significantly higher in high turnover states compared to low turnover (p=0.021). Taken together, this study validates the use of AIHC TRAcP on undecalcified bone tissue EFMMAE as an effective technique for Oc detection and outperformed Oc count by standard GTS method, especially in the high turnover states. AIHC should be considered as an alternative and easier method to EHR TRAcP. To our knowledge, this is the first time that AIHC has been successfully performed on undecalcified bone tissue EFMMAE, paving the way for the detection of other cellular biomarkers for clinical purposes.

Does Bisphosphonate therapy in osteoporosis impact the ability to diagnose primary hyperparathyroidism? *Madhumathi Rao[1], Lawrence Butros[2], Jonathan Webb[3], Hafsa Nebbache[4], Dana Richards[4], Hartmut Malluche[5]. [1]University of Kentucky, . [2]University of Kentucky Internal Medicine, United States. [3]University of Kentucky - Division of Nephrology, . [4]University of Kentucky Pathology and Laboratory Medicine, United States. [5]University of Kentucky Medical Center, United States

Introduction:Primary hyperparathyroidism (PHPT) is now a largely asymptomatic disease, often found incidentally during workup for end organ damage such as osteoporosis (OP). Patients may also be normocalcemic, with only intermittent serum calcium elevation, and remain undiagnosed unless parathyroid hormone (PTH) is checked and found elevated or non-suppressed. Bisphosphonate (BP) therapy is first line for post-menopausal osteoporosis (PMO) and is also recommended in PHPT, as an approach to stabilize bone mineral density (BMD) and offset bone loss.Clinical Cases:We describe the clinical course of three female patients (age 71-80 yrs) with PMO referred to the UK Bone Clinic for worsening BMD despite extended treatment with a bisphosphonate (4-16 yrs). Detailed workup for causes of declining bone density (table 1) showed elevated serum calcium with non-suppressed or elevated PTH, with vitamin D replete status. Bone turnover markers were not elevated, prompting performance of undecalcified bone biopsy with double tetracycline labeling for a better characterization of bone turnover. Paradoxically the biopsy showed evidence of low bone turnover, with resorptive changes and frequent dysmorphic osteoclasts. Further workup with neck ultrasound and sestamibi scans supported parathyroid adenoma. All underwent surgical intervention with subtotal parathyroidectomy, histology showed hypercellular parathyroid. Clinical Lesson:The three patients in this report all had initial diagnosis of PMO and were started on BP therapy. Years later, referral for declining bone density triggered further workup, revealing underlying PHPT but with the phenotype radically altered by BP. We posit that while anti-resorptive therapy addresses bone loss, it could potentially mask a diagnosis of PHPT. Given the population overlap of PHPT and PMO, we propose that diligent efforts should be made to evaluate patients for PHPT prior to treatment with BP, with frequent review subsequently. Of note we also stress the importance of recognizing a non-suppressed PTH in patients with elevated calcium level as an important indicator of PHPT.

	Patient A	Patient B	Patient C
Risk Factors for OP	Glucocorticoids use, Smoking	Early surgical menopause, Family history	Early menopause, Weight loss
Lab Evaluation			
Serum Creatinine (0.6 - 1.10 mg/dL)	1.35	0.66	1.24
Serum Calcium (8.6 - 10.2 mg/dL)	11.1	10.5	10.6

What are we measuring with the 18F-NaF PET/CT in bone diseases? A systematic review of the validation of quantitative 18F-fluoride PET/CT uptake parameters in bone disease *Ruben de Ruiter[1], Jolien Zwama[1], Pieter Raijmakers[2], Maqsood Yaqub[2], Marelise Eekhoff[1]. [1]Department of Endocrinology and Metabolism, Amsterdam University Medical Centers (UMC), Vrije Universiteit, Amsterdam Movement Sciences, Netherlands. [2]Department of Radiology and Nuclear Medicine, Amsterdam University Medical Centers (UMC), Vrije Universiteit, Netherlands

Purpose: The 18F-NaF PET/CT has become an increasingly important tool in clinical practice towards understanding and evaluating diseases and conditions in which bone metabolism is disrupted. Nonlinear regression (NLR) analysis with a two tissue compartment model to determine uptake (Ki) of 18F-fluoride with full dynamic analysis is considered the gold standard for quantification of 18F-fluoride uptake. However, full dynamic analysis is often impractical in a clinical setting, leading to the de development of more simplified semi-quantitative parameters.Methods: We performed a literature search (in PubMed, Embase and Web of Science), including studies using the 18F-NaF PET/CT to measure disease activity in bone-related disorders. Our goal was to first explore if the reported uptake values were validated against full dynamic analysis. Secondly, to investigate if the chosen uptake parameter correlated with a disease specific outcome or marker, validating its use as a clinical outcome or disease marker.Results: Our initial search included 1627 articles leading to 53 studies spanning 27 different bone related conditions in which the 18F-NaF PET/CT was used to quantify 18F-uptake. These were subcategorized into metabolic bone diseases (12 articles), surgery (21 articles), arthritic conditions (16 articles) or other (4 articles). In 7 bone related disorders, dynamic analysis was performed and compared to the thereafter used simplified uptake parameter. The simplified uptake parameters showed a large heterogeneity. SUVmean and SUVmax were most frequently used, though normalization of these values varied greatly between the studies. In some disorders, multiple studies were performed evaluating 18F-uptake as a marker of bone metabolism, however in those cases, the used 18F-uptake was often different for each separate study, making comparison in 18F-uptake reflecting bone turnover as an outcome measure between studies not possible.Conclusions: Should we want to use the 18F-NaF PET/CT to evaluate disease activity or treatment response in various bone related disorders, it is essential to standardize our approach. Ideally the most suitable parameter is determined through dynamic analysis, followed by comparison to simplified uptake parameters and to standardized disease specific biomarkers or outcome of interest.

Understanding the pathophysilogical link between Alzheimer's disease and osteoporosis. *Sarika Gupta[1]. [1]National Institute Of Immunology, India

Patients with Alzheimer's disease usually have low bone mineral density (BMD) and are more prone to Bone fractures than healthy individual. However, the mechanism behind the accelerated bone loss in AD pateints is unknown. We wanted to understand how the 3XFAD mouse model of familial Alzheimer's disease (FAD) affects age-dependent alteration in bone parameters. According to earlier research, women are more likely than men to experience osteoporosis and AD. In our research, we found that both male and female FAD mice had degeneration in bone micro architecture, with females exhibiting a greater degree of deterioration than males. With age, these alterations in bone micro architecture are seemed to become more pronounced. The mechanical properties of bone, such as bone strength, stiffness, and energy stored in bone, are substantially impaired in FAD mice. Furthermore, in both AD and the presence of the neurotoxic peptide A?42, bone marrow stem cell (BMSC) differentiation to osteoclast was considerably increased, but differentiation to osteoblast was severely impaired. Also, serological studies showed a rise in pro-inflammatory cytokines such as TNF alpha, IL17, and IL18 in AD mice. Increased levels of proinflamatory cytokines have been proven to stimulate osteoclastogenesis. These findings lead us to the conclusion that bone tissue in AD mice begins to deteriorate at a young age, even before AD pathology is evident.

Effectiveness of Asfotase Alfa for Treatment of Adults With Hypophosphatasia: Results from a Global Registry *Priya S. Kishnani[1], Gabriel Ángel Martos-Moreno[2], Agnès Linglart[3], Anna Petryk[4], Andrew Messali[4], Shona Fang[4], Cheryl Rockman-Greenberg[5], Keiichi Ozono[6], Wolfgang Högler[7], Lothar Seefried[8], Kathryn M. Dahir[9]. [1]Duke University Medical Center, United States. [2]Hospital Infantil Universitario Niño Jesús, IIS La Princesa, Universidad Autónoma de Madrid, CIBERobn, ISCIII, Spain. [3]Paris-Saclay University, AP-HP and INSERM, France. [4]Alexion, AstraZeneca Rare Disease, United States. [5]University of Manitoba, Canada. [6]Osaka University, Japan. [7]Johannes Kepler University Linz, Austria. [8]University of Würzburg, Germany. [9]Vanderbilt University Medical Center, United States

Objectives: To assess asfotase alfa's effectiveness on mobility, functional status, quality of life (QOL), and pain in adults with hypophosphatasia (HPP).Methods: Patients enrolled in the Global HPP Registry (NCT02306720; EUPAS13514) who had an alkaline phosphatase below the LLN for age and sex and/or a documented ALPL gene variant, initiated asfotase alfa at age >=18 years, and been treated for >=6 months at last follow-up were included. Outcomes were evaluated as mean change from mean baseline (BL) value through 36 months; assessments were not performed at all timepoints for all patients.Results: Among included patients (N=190), median age at treatment start was 45.5 years; 91.1% were characterized as having pediatric-onset HPP. 6MWT distance walked was 404 m (n=31) at BL and improved over time vs BL (change: 93 m at 12 months [95%CI: 47, 138; n=18], 62 m at 24 months [95%CI: 0, 124; n=15], and 45 m at 36 months [95%CI: ?83, 172; n=7]). The SF36v2 Physical Component Summary score was 35.7 (n=48) at BL and improved over time (change: 4.68 at 6 months [95%CI: 0.16, 9.21; n=34], 4.61 at 12 months [95%CI: 1.02, 8.19; n=28], 4.94 at 24 months [95%CI: ?2.23, 12.11; n=22], and 5.13 at 36 months [95%CI: ?0.96, 11.21; n=21]). SF36v2 Mental Component Summary score improvements were not statistically significant at all timepoints. Health Assessment Questionnaire-Disability Index scores were generally unchanged over time. Self-reported Brief Pain Inventory Short Form scores improved at all timepoints from a BL of 4.86 (change: ?0.72 at 6 months [95%CI: ?1.23, ?0.21; n=38], ?1.07 at 12 months [95%CI: ?1.62, ?0.52; n=31], ?1.13 at 24 months [95%CI: ?1.76, ?0.51; n=26], and ?0.97 at 36 months [95%CI: ?1.70, ?0.24; n=23]). The most common AEs were injection site reactions and injection-associated reactions, occurring in 29 (13.4%) and 13 (6.0%) patients, respectively. Eleven serious AEs related to asfotase alfa were reported in 7 patients.Conclusion: Adults with HPP who received asfotase alfa for >=6 months experienced improvements in mobility, physical function, QOL, and pain, which were maintained over 3 years of follow-up.

Coexisting Primary Hyperparathyroidism and Sarcoidosis in a Patient with Recurrent Hypercalcemia *Yasaman Motlaghzadeh[1], Marina Basina[2], Deborah Sellmeyer[3]. [1]Stanford University School of Medicine, . [2]Stanford University School of Medicine , United States. [3]Stanford University, School of Medicine, United States

Background: Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia in ambulatory patients. Hypercalcemia associated with elevated levels of 1,25-dihydroxyvitamin D occurs in 10-20% of patients with sarcoidosis. However, the consecutive occurrence of these conditions is rare. We present a patient with PHPT who experienced recurrent hypercalcemia after parathyroidectomy and was subsequently diagnosed with sarcoidosis. Clinical Case: A 69-year-old woman with a history of osteoporosis presented in 2019 with hypercalcemia. Between February 2019 and March 2021 serum calcium ranged from 10.5 to 11.2 mg/dL (ref range: 8.5-10.5 mg/dL), phosphorus ranged from 3.0 to 3.4 mg/dL (ref range: 2.5-4.5 mg/dL), parathyroid hormone (PTH) ranged from 89 to 150 pg/mL (ref range: 15-65 pg/mL), glomerular filtration rate ranged from 54 to 67 mL/min (ref range: >60 mL/min), 25-hydroxy vitamin D level was 24 ng/mL (ref range: 30-100 ng/mL), and calcium: creatinine clearance ratio of 0.015. In March 2021, Sestamibi scan showed a left upper parathyroid adenoma. Following the removal of the adenoma in June 2021, her serum PTH and calcium concentrations declined from 150 to 41 pg/mL and from 11.2 to 9.8 mg/dL, respectively, one-week post-surgery. Pathology report showed hypercellular parathyroid tissue without atypia consistent with parathyroid adenoma. In March 2022, she returned to the clinic with a serum calcium level of 12 mg/dL. Further workup showed a suppressed PTH level of 8 pg/mL (ref range: 10-65 pg/mL) and an elevated 1,25-dihydroxyvitamin D level of 80 pg/mL (ref range: 18-78 pg/mL). The patient underwent a chest CT scan, which showed enlarged mediastinal lymph nodes, followed by endobronchial ultrasound-guided fine-needle aspiration. Pathology showed lymphocytes and collections of histiocytes with features of granuloma; acid-fast and fungal stains were negative. Further testing revealed an elevated angiotensin-converting enzyme level of 65 U/L (ref range: 8-52 U/L), supporting the diagnosis of sarcoidosis. The patient was started on prednisone 20 mg daily and her calcium level normalized within 2 weeks. Conclusion: This case highlights the importance of a thorough evaluation during recurrent hypercalcemia even in patients who previously have been found to have PHPT. While rare, PTH mediated and PTH independent hypercalcemia can occur in the same patient and a complete evaluation is essential to avoid misdiagnosis and unnecessary procedures.

SUN-008

Bone Disorganization: A Novel Biomarker Unrelated to Bone Density and Structure that May Hold the Key to The Diagnosis of Atypical, Unusual, or Stress Fractures *Roger Zebaze[1], Cat Shore-lorenti[2], Cherie Chiang[3], Kevin Djopseu[4], Tessa Makebeh[4], Simon Zhang[2], Fran Milat[5], Peter Ebeling[6]. [1]Monash University, . [2]Department of Medicine, School of Clinical Sciences, Monash University, Australia. [3]Department of Endocrinology, Austin Health, Australia. [4]Zeze co, Cameroon. [5]Hudson Institute of Medical Research, Australia. [6]School of Clinical Sciences, Monash University, Australia

Purpose- The cause of many fragility fractures remains a mystery as they are unexplained by reduced bone mineral density (BMD) or degraded microarchitecture. To address this enigma, we recently proposed that fragility in these patients is due to the incorrect arrangement of an otherwise sufficient or even high amount of normal bone tissue (disorganization). Incorrectly positioned (disorganized) components by abnormally transferring loads cause damage; triggering inflammation, and a vicious cascade of events leading to abnormalities and fractures. We further developed and validated a tool to quantify this novel biomarker (disorganization). Here, we test the hypothesis that measures of disorganization are unrelated to bone density or decay, YET associated with Atypical Femoral Fractures (AFFs), Paget Disease of Bone (PDB), and Hypophosphatasia (HPP) (all diseases in which bone is fragility unexplained by BMD or structural decay).Methods-We studied 45 women (10 AFFs and 35 fracture-free peers) mean (SEM) age 68.1(1.83)yrs. In addition, we studied patients withPDBs (2) and HPPs (2). Curves displaying the extent disorganization along the femoral shaft (ALIGNOGRAM) were produced and metrics of disorganization were quantified as previously reported (Zebaze et al, JBMRPlus 2023). Correlations between disorganization metrics, bone structure, and density were assessed.Results-In normal subjects, ALIGNOGRAMs were relatively flat and regular with low Disorganization values (DVs); no abrupt peaks. In all patients with AFFs, PDBs, and HPPs ALIGNOGRAMs were irregular, chaotic with higher DVs and spike-shape peaks corresponding to the most disorganized part of bones (Fig 1). The mean DV (MDV) distinguished AFFs from controls [36.3 (IQR 23.9-60.8) vs 3,139 (IQR 1212-14788)]; p<0.0001. However, DVs along the femur were unrelated to mass or structure. The MDV was not correlated with lateral and medial cortical thicknesses, or periosteal diameter (All R2<0.001; NS). The MDV was also unrelated to density (R2=0.0002; p=0.17).Conclusion-Disorganization is a novel mechanism and a biomarker of bone fragility completely unrelated to bone mass and microarchitecture. This novel biomarker, readily quantifiable from standard X-rays, may hold the key to the cause of fractures that occur in individuals without reduced bone density or structural decay such as AFFs, HPP, or PDB. Larger studies are now needed in larger populations with different bone diseases to confirm our findings.

Measuring FGF23 in patients treated with Burosumab *Isabelle Piec[1], Allison Chipchase[2], Emma Miler[3], Hari Ramachandran[1], Emma Webb[3], WILLIAM FRASER[4]. [1]University of East Anglia, United Kingdom. [2], . [3]Norfolk and Norwich University Hospitals, United Kingdom. [4]UNIVERSITY OF EAST ANGLIA, United Kingdom

X-linked hypophosphatemia (XLH) is a hereditary, progressive, and lifelong condition that affects both children and adults with an incidence of 1/20,000. The disease is characterised by elevated circulating fibroblast growth factor 23 (FGF23). High FGF23 induces hypophosphatemia, reduced 1,25 Dihydroxyvitamin D concentration and defective bone mineralisation (osteomalacia/rickets). Treatment with burosumab, a fully human IgG1 monoclonal antibody that binds intact FGF23 (iFGF23) decreases rickets severity, prevents enthesiopathy, improves growth, increases serum phosphate and 1,25(OH)2D as well as the ratio of tubular maximum reabsorption rate of phosphate to glomerular filtration rate (TmP/GFR). However, symptoms in some patients are not fully resolved suggesting some free iFGF23 may remain circulating and acting in these patients while concomitantly paediatricians are keen to measure FGF23 to avoid overtreatment with associated potential calcification risk. Measuring FGF23 in patients treated with burosumab is problematic as we and others have observed interference (false positive) of the therapeutic antibody in multiple assays (Immutopics c-terminal FGF23 [cFGF23], MedFrontiers and Immutopics iFGF23) while being seemingly low/normal in the DiaSorin iFGF23 (false negative). We immunoprecipitated burosumab using magnetic A/G beads from samples obtained from treated patients. Cleanliness of the supernatant was checked by western blot and FGF23 was then measured in the supernatant using Immutopics cFGF23. This ELISA measures both intact and cFGF23. We also analysed for the presence of cFGF23 alone by western blot using anti-cFGF23 (186-206) antibody (Quidel). We were only able to detect intact FGF23 by these methods suggesting that either there is no free cFGF23 present or the technique is not sensitive enough to detect the circulating concentration of cFGF23 fragment in patients treated with burosumab. The presence of sufficient circulating intact FGF23 and absence of cFGF23 in patients treated with burosumab could explain the persistence of some symptoms of XLH. In future we may be able to correlate outcome with circulating concentrations of free iFGF23. The changes in efficacy of burosumab in older children and adolescents may partly reflect a requirement for an increased dose of burosumab to fully capture iFGF23.

Evaluation of Bone Mineral Density and Microarchitecture using Trabecular Bone Score in Adults with X-Linked Hypophosphatemic Rickets *Luciana Valadares[1], Larissa Moreira[2], Bernardo Cunha[3], Bruno Ferreira[4]. [1]SARAH Network of Rehabilitation Hospitals, . [2] SARAH Network of Rehabilitation Hospitals, Brazil. [3]Universidade do Planalto Central Apparecido dosSantos (UNICEPLAC), Brazil. [4]Centro Universitário Serra dos Órgãos, Brazil

Introduction: X-linked hypophosphatemia (XLH), caused by inactivating mutations in the phosphate regulating endopeptidase homolog X-linked (PHEX) gene, represents the main cause of hereditary hypophosphatemic rickets. Elevated bone mineral density (BMD) of the lumbar spine (LS) has been detected in patients with XLH using dual-energy X-ray absorptiometry (DXA), even in the absence of enthesopathies and/or extraskeletal calcification. Trabecular bone score (TBS) can be used to indirectly assess the bone microarchitecture using DXA images of the LS. However, its utility in patients with XLH is still undefined. Objectives: To evaluate the BMD and microarchitecture in adults with XLH using TBS and to analyze the correlation of the clinical and biochemical parameters with BMD and TBS. Methods: This cross-sectional study included adult patients (aged >18 years) from a single tertiary center in Brazil with XLH confirmed by the occurrence of PHEX mutations. Information pertaining to clinical, biochemical, and densitometric parameters of the patients was retrieved from their medical records. The BMD of three skeletal sites (LS, femoral neck, and total hip) was measured using DXA. TBS was obtained from LS DXA images using the TBS iNsight software. Results: The study group consisted of 16 adults with XLH (15 women and 1 man) with a mean age and height of 30.9 years (+/-12.5) and 143.1 cm (+/-11.7), respectively. Seven patients had an LS BMD Z-score > 2, whereas only 1 had an LS Z-score < -2. The BMD Z-score of LS was significantly higher (median 1.8, range -2.1 to 5.9) than that of the total hip (median 0.2, range -2.1 to 1.3) ($p = 0.028$) and femoral neck (0.6, range -2.0 to 0.6) ($p = 0.023$). There was no correlation between the LS BMD and age ($r = 0.407$, $p = 0.118$), height ($r = 0.186$, $p = 0.491$), body mass index (BMI) ($r = 0.278$, $p = 0.297$), or the biochemical parameters analyzed. The mean TBS was 1.637 (+/-0.12), and no patient showed compromised bone microarchitecture (TBS < 1.350); TBS did not correlate with any of the clinical, densitometric, or biochemical parameters evaluated. Conclusion: We found that adults with XLH had increased BMD in LS when compared with that in total hip and femoral neck, suggesting that the effect of the disease on the axial skeleton differs from that on the appendicular skeleton. No bone microarchitectural compromise was detected using TBS, and the value of using TBS in patients with XLH remains unclear.

Temporal Trend of Mortality in Paget's Disease Over 20 years in Quebec, Canada *Laetitia Michou[1], Philippe Gamache[2], Isaora Zefania Dialahy[2], Jason R Guertin[3], Jean-Eric Tarride[4], Jacques P Brown[5], Sonia Jean[2]. [1]Universite Laval, Canada. [2]Institut national de santé publique, Canada. [3]Department of preventive and social medicine and CHU de Québec-Université Laval research centre, Canada. [4]Department of Health Research Methods, Evidence and Impact, Faculty of Health Sciences, Canada. [5]CHU de Québec-Université Laval research centre and Department of Medicine, Université Laval, Canada

Purpose - Paget's disease of bone (PDB) is a chronic focal late-onset metabolic bone disorder. A decline of prevalence, incidence and severity of PDB has been reported in several countries. Although our team has reported a stable prevalence of PDB in Quebec (Canada), the incidence was found to decrease over time. This study aimed at determining the evolution of the mortality in patients with PDB in the province of Quebec by analyzing the medico-administrative data of the Regie de l'assurance maladie du Québec (RAMQ) and to compare it with the general population aged >= 55.Methods - For each fiscal year, the adjusted rate of all-causes mortality in individuals aged >= 55 with PDB and the general population, was determined using the RAMQ data from 2000/2001 to 2020/2021 (population size 2,913,820 in 2019/2020). The case definition relied on one hospitalization or two claims from physicians with the diagnosis code of PDB (CIM-9: 731.x except 731.2, CIM-10: M88). The adjusted rate of mortality was determined in men and women, and by age categories (55-64 years, 65-74 years, 75-84 years and >= 85 years) for each year from 2000/2001 to 2020/2021. The standardized mortality rates ratios and 95% confidence interval were calculated. The percentage of death for each main cause of death was described.Results - The adjusted rate of all-cause mortality in individuals with PDB aged >= 55 varied from 47.1/1000 in 2000-2001 to 54.1/1000 in 2020-2021 (Fig. 1). In the general population, the adjusted mortality rate varied from 27.6/1000 in 2000-2001 to 22.3/1000 in 2020-2021. The absolute number of deaths in individuals with PDB aged >= 55 varied from 410 in 2000-2001 to 655 in 2019-2020. The increase in adjusted rate of mortality in PDB was observed in both men and women. The highest increase in standardized mortality rates ratios in individuals with PDB was observed in the age category of 55-64 years, from 1.90 (0.84-4.30) in 2000-2001 to 11.3 (7.48-16.9) in 2019-2020, followed by the age category of 65-74 years. The most frequent causes of death in individuals with PDB were cardiovascular diseases (27%), cancer (24%) and respiratory

diseases (8%), versus 22%, 31% and 8% in the general population, respectively.Conclusions - We observed an apparent increase in adjusted rate of mortality in individuals with PDB. This increase may be explained by an aging effect of the cohort with PDB in relation with an accelerated decline of incidence of PDB during the past six years.

SUN-015

Association of parathyroid hormone and hyperparathyroidism on thromboembolic events: a systematic review and meta-analysis *Ernest Zhi Tay[2], Clarise Lam[2], Alexander Rodriguez[2]. [2]Monash University, Australia, [2]Monash University,

Introduction: Parathyroid hormone (PTH) regulates calcium homeostasis. Calcium plays an important role in the coagulation cascade. Calcium supplementation has been shown to transiently increase thrombotic potential. However, there is limited evidence on the role of PTH in thromboembolism. We hypothesised that hyperparathyroidism (HPT) would be associated with thromboembolic events. We also hypothesised that PTH would be associated with thromboembolic events.Method: EMBASE, MEDLINE and ClinicalTrails.gov were searched from inception to 4/8/22 for studies investigating HPT and PTH on acute myocardial infarction (aMI) and stroke. Two independent reviewers screened and extracted data and assessed bias. Random effects models were fitted for meta-analysis and tau2 was reported to investigate effect variance.Results: 3061 records were identified of which 67 articles met our inclusion criteria and 13 studies had outcome data for aMI and stroke enabling meta-analysis. Studies were of low-moderate quality. Study population ranged from 218 to 180,114. Two studies specifically enrolled patients with HPT. Studies applied a threshold of 65pg/mL to determine 'high' PTH. Meta-analysis of five studies comparing high vs. low (<=65pg/mL) PTH showed high PTH was associated with a non-significant increased risk of aMI (RR=1.35 [0.80 to 2.28], tau2 =0.313, n=189,479) but there was an approximate 37% increased risk of stroke (RR=1.37 [1.20 to 1.56], tau2 =0.000, n=291,335). A meta-analysis of four studies examining per 10pg/mL increase in PTH showed that there was an increased risk of aMI (RR=1.36 [1.00 to 1.85, tau2 =0.052, n=3430). When excluding patients with HPT, higher PTH was associated with non-significant increased risk of aMI (RR= [0.99 to 2.52], tau2 =0.198, n=188,274) and stroke [RR=1.33 [0.93 to 1.91], tau2 =0.063, n=3962). In cross-sectional analyses, there was a greater serum level of PTH in patients with an aMI compared to those without (SMD=0.35 [0.25 to 0.44], tau2 =0.031, n=8178, five studies). Interpretation: We showed that (i) HPT was associated with an increased risk of stroke and (ii) PTH levels are higher in individuals with acute MI but this was not associated with MI risk. These data indicate that optimisation of cardiovascular risk should be considered by clinicians treating patients found to have elevated PTH levels. There is scant data for these outcomes in patients with HPT warranting further investigation.

COX2-independent Effects of the NSAID Naproxen on Bone *Alexandra Ciuciu[1], Ryan Tomlinson[2]. [1]Thomas Jefferson University , , [2]Thomas Jefferson University, United States

Non-steroidal anti-inflammatory drugs (NSAIDs) inhibit the cyclooxygenase (COX) enzymes COX1 and COX2 that produce prostaglandins driving pain and inflammation. We reported that adult female C57BL/6J mice treated with naproxen for 15 days had significantly decreased bone toughness, reduced strain adaptive bone remodeling, and diminished woven bone formation during stress fracture repair. We also found that naproxen decreased osteocyte dendrite number and the number of MMP13+ osteocytes as compared to vehicle in male mice. Since these effects on bone toughness and healing were not observed in mice treated with the COX2-specific inhibitor, celecoxib, we hypothesized that the effects of naproxen on osteocytes and bone toughness were COX2-independent. To test this hypothesis, naproxen sodium (10.9 mg/kg) or vehicle (ddH2O) was administered to adult (15-18 weeks old) Ptgs2-Y385F and wild-type (WT) mice for 15 days. Mice received six bouts of axial forelimb compression using a 2 Hz rest-inserted sinusoidal waveform of 3 N for 100 cycles. Calcein and alizarin red were injected on day 5 and 12 respectively; drinking water was refreshed every 2-3 days. Right femurs were stored in PBS-soaked gauze at -20ºC before analysis. Both forelimbs were harvested, fixed, embedded in PMMA, sectioned using a low-speed saw, and imaged using confocal microscopy. First, we observed that naproxen significantly decreased trabecular bone volume fraction in Ptgs2-Y385F male mice (-21.5%, p=0.0055) as compared to vehicle treated mice; this effect was not significant in WT male mice or in female mice of either genotype. Next, we found that naproxen significantly decreased bone toughness by three-point bending across all genotypes and sexes (male: p=0.0004; female: p=0.0279; by two-way ANOVA). Surprisingly, naproxen also significantly decreased whole bone bending (section modulus vs. bending moment) intercepts in WT mice (male: p=0.0204; female: p=0.0399) but not Ptgs2-Y385F mice. Finally, we observed that naproxen treatment significantly diminished relative periosteal bone formation rate per bone surface in male Ptgs2-Y385F and WT mice (-28% in Ptgs2-Y385F; -58% in WT; p=0.047 by two-way ANOVA) by dynamic histomorphometry. These results demonstrate COX2-independent effects of naproxen on bone toughness. On-going studies will identify these COX2-independent mechanisms to improve therapeutic options for relief of musculoskeletal pain without impairing bone mechanical properties.

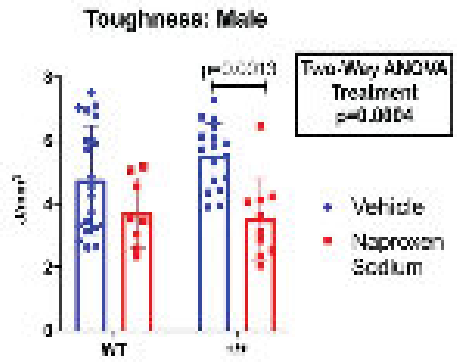

Figure 1: Average bone toughness as determined by standard 3-point bending for vehicle and naproxen sodium treated wild-type (WT) and Ptgs2-Y385F (+/+) mice. (n=8-20 per genotype)

Mechanisms of Bone Fragility with Skeletal Growth in Osteogenesis Imperfecta *Anxhela Docaj[2], Asier Muñoz[2], Alessandra Carriero[2]. [2]The City College of New York, , [2]The City College of New York, United States

In classical osteogenesis imperfecta (OI or brittle bone disease) mutations in the genes encoding collagen type I alter collagen structure resulting in bone fragility [1]. We showed that bone fracture resistance is low in the homozygote oim mouse model of OI [1], already at a very young age, with bones getting tougher as the mouse grows and matures [2]. The mechanisms by which OI bone resists fracture varies with skeletal growth. Crack path examination showed for the first time the presence of crack deflections, splitting, and bridging in young (4 w.o.) oim bones, but not in more mature (14 w.o.) ones [2]. These are toughening mechanisms usually observed in healthy bone. Young oim mouse bone showed low resistance to fracture even before the crack forms but not while it grows, while mature oim mouse bone exhibited low toughness during crack grow but not at crack initiation. To determine the mechanisms of bone fragility in oim bones at these stages of skeletal growth, and explain the observed differences in fracture toughness, we here examine changes in the oim bone tissue structure and composition at different ages. We assessed oim bone intracortical porosity with synchrotron microtomography, quantified collagen composition, fibers orientation and organization in oim bones using second harmonic generation microscopy, and determined bone tissue composition, and the presence of advanced glycation end products (AGEs) using Raman spectroscopy and molecular fluorescence. Compared to mature oim bone, young oim bone tissue exhibit high lacunar porosity density, low collagen content, disorganized mineralized fibers with low carbonate substitution and mineral crystallinity, and high CML/CH2-wag and florescent AGEs. These parameters describe a poorly organized bone tissue in young oim mice that can explain their lower fracture resistance compared to mature bone. Cracks favorably initiate in presence of defects, such as lacunae porosity, and in tissue with low plasticity due to poor collagen and mineral properties and interaction. Furthermore, the

increased number of AGEs per collagen content, together with the reduced collagen content, further underlines the controversial role that non-enzymatic crosslinks could possibly have in oim bones. This study suggests that treatments for OI bone fragility should differ in young and mature populations, targeting two different mechanisms of bone fragility.1. A. Total Body Irradiation Results in Deficits in Vertebral Bone Structure and Mechanical Properties in Male Rhesus Macaques *Shannon Emerzian[1], Isabel Barnet[2], Trinity Tedtsen[3], Daniel Brooks[4], Sun Park[5], Joseph Moore[5], John Olson[5], Mary Bouxsein[6], J. Mark Cline[5], Jeffrey Willey[5]. [1]Beth Israel Deaconess Medical Center, United States; [2]Harvard Medical School, ; [3]Massachusetts General Hospital, United States; [4]BIDMC/MGH, ; [5]Wake Forest University School of Medicine, United States; [6]Beth Israel Deaconess Medical Center, Harvard Medical School, United States

Patients undergoing high-dose radiation therapy (RT) for cancer treatment have an elevated fracture risk, particularly in healthy bones that absorb dose. However, the effects of low-dose total body irradiation (TBI) on skeletally-mature bone are unclear; determining these responses can help develop countermeasures for adult survivors of radiologic events (e.g, “dirty bomb”). This study quantified aging and late effects of TBI on bone microstructure in rhesus macaque (Macaca mulatta) non-human primates (NHPs).Femora and lumbar vertebrae (LV) were obtained post-mortem from 3 groups of skeletally-mature male NHPs: TBI (n=7 femora; n=5 LV, 18.9+/-2.5yrs of age), age-matched non-irradiated (NR) Controls (n=6 femora; n=4 LV, 18.7+/-2.0yrs), and NR Young NHPs (n=6 femora; n=6 LV, 9.1+/-0.1yrs). TBI received an acute dose of 6.0-6.75Gy. Tissues were harvested ~10yrs after TBI. High-resolution computed tomography (CT, Scanco) scans were used to assess trabecular (Tb) microarchitecture of LV and distal femur; cortical (Ct) bone was assessed at femoral mid-diaphysis. Micro-finite element analysis (µFE) of LV was computed using CT scans. Urinary N-terminal telopeptide crosslinks (NTX) were quantified via ELISA at sacrifice. One-way ANOVA and Tukey post-hoc tests assessed group effects. Data are presented as mean+/-SD; percent differences are calculated between group means.Body mass varied by group, with Young NHPs (18.1+/-3.3kg) larger than TBI (13.9+/-2.7kg, p=0.01) and Controls (14.4+/-4.1kg, p=0.04). TBI resulted in LV Tb deficits: lower bone mineral density (BMD, -20%, p=0.04) and bone volume fraction (BV/TV, -27%, p=0.03) vs Controls (Fig A). LV Tb BMD and BV/TV were similarly lower in TBI vs Young NHPs (-20%, p=0.07; -26%, p=0.04, respectively). µFE stiffness, ultimate force, and apparent modulus were lower in TBI vs Controls (-34%, p=0.11; -30%, p=0.15; -33%, p=0.11) and Young (-37%, p=0.04; -34%, p=0.05; -56%, p=0.048, Fig B). No differences between Control and Young NHPs were detected in LV microarchitecture or µFE measures. By contrast, at the femur, Controls had reduced Tb BMD (-28%, p=0.058) and BV/TV (-32%, p=0.04) vs Young NHPs (Fig C). Yet, TBI had no measurable effect on distal femur Tb bone, Ct bone area (Fig D) and NTX levels vs Young and Control.In the axial skeleton of NHPs, TBI diminished Tb bone microstructure and strength, suggesting TBI exposure could elevate vertebral fracture risk in adult survivors after intentional or accidental radiologic events.

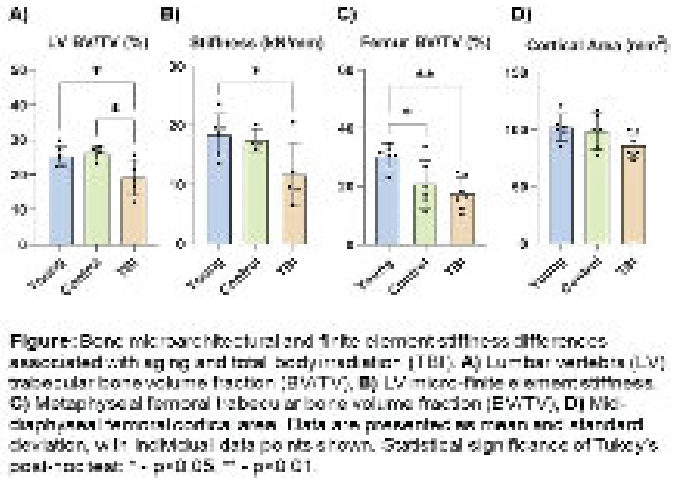

Figure: Bone microarchitectural and finite element stiffness differences associated with aging and total body irradiation (TBI). A) Lumbar vertebra (LV) trabecular bone volume fraction (BV/TV), B) LV micro-finite element stiffness, C) Metaphyseal femoral trabecular bone volume fraction (BV/TV), D) Mid-diaphyseal femoral cortical area. Data are presented as mean and standard deviation, with individual data points shown. Statistical significance of Tukey's post-hoc test: * - p<0.05, ** - p<0.01.

Risk of Vertebral Endplate Failure During Vertebral Fracture *ELISE MORGAN[2], Neilesh Frings[2]. [2]Boston University, United States; [2]Boston University,

Vertebral fracture (VF) is the most common type of osteoporotic fracture1. The vertebral endplate region comprises the cartilage endplate, vertebral endplate (VEP), and underlying subchondral trabecular bone (STB). The endplate region plays a critical role in spinal loading and is frequently involved in VF. Although fracture of the VEP does not always occur during VF2,3, VEP fracture is associated with a higher risk of future disc degeneration and worsening of the VF over time3,4. The conditions responsible for VEP failure are unclear; their identification can aid in evaluating risk of, and prognosis following, VF5. This study used high-resolution micro-finite element (µFE) models to evaluate relative risk of failure in the VEP, STB, and other portions of the vertebral body at the point of onset of VF, and whether the relative risk of VEP failure is associated with VEP and STB microstructure. Models were built from micro-CT scans (0.074mm resolution) of L1 vertebrae (n=21) previously scanned and mechanically tested2. Superior and inferior boundaries of the models were prescribed sample-specific experimentally matched displacements corresponding to the yield point of the compression test. Volumes of interest (VOIs) were defined on coronal image slices and mapped to the model: VEP, STB, and remaining portion of the vertebra, defined as the mid-vertebral body (MVB). Tissue yield was defined by principal strain thresholds reported for trabecular tissue. High strains in the vertebrae were frequently observed in the superior endplate and cortical shell (Figure). The proportion of elements that yielded varied among vertebrae, ranging from 8% to 0.01% of elements, and was not different among VOIs. When normalized to the sample-specific amount of yield, however, the VEP exhibited greater risk of failure than the STB and MVB. These results indicated that at the onset of VF, tissue-level yield typically occurs in the VEP, and to a lesser extent, the rest of the vertebral body. VOI yield fractions did not correlate to average measures of microstructure in the VOIs, suggesting that other factors are responsible for which regions fail first. Overall, these findings emphasize the importance of the VEP in VF pathogenesis. References: [1] Cooper, C., et al., Am J Epi 1993. [2] Hussein, A.I., et al., J Biomech Eng 2018. Effect of Red Rooibos Consumption on Bone Mineral and Structure in Rats Post-Lactation *Matthew K. Goncharow[1], Jenalyn L. Yumol[1], Michael D. McAlpine[1], Wendy E. Ward [1]. [1]Brock University, Canada

In rats, pregnancy and lactation challenges the maternal skeleton to support skeletal growth of offspring. We previously showed that red rooibos tea (RR) fed pre-pregnancy through to 4 months post-lactation supported a partial recovery in trabecular bone mineral density (BMD) and structure in tibia. The study objective was to determine if RR intake results in similar femur and lumbar vertebrae (L4) BMD and bone structure 4 months post-lactation compared to rats that did not experience pregnancy. Female Sprague-Dawley rats were randomly assigned to one of three groups: 1) no pregnancy+water (GROWTH CON; n=14); 2) pregnancy and lactation+water (PREG CON; n=12); and 3) pregnancy and lactation+water with RR (~2.6 g of red rooibos/kg body weight/day) (PREG TEA; n=14). RR intervention began pre-pregnancy (age 6 weeks) through to 4 months post-lactation (endpoint). Ex vivo measurement of whole femur and L4 area, bone mineral content (BMC) and BMD was conducted using dual X-ray absorptiometry (Scintica InSiGHT) and trabecular (femur neck, L4 body) and cortical bone structure (midpoint of the femur, L4 body) was quantified using micro computed tomography (Skyscan 1176). At femur neck, there were no differences in trabecular bone structure outcomes including bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), and trabecular separation (Tb.Sp) among groups. In contrast, cortical bone structure at femur midpoint was different among groups: GROWTH CON had higher cortical area fraction (Ct.Ar/Tt.Ar) and cortical thickness (Ct.Th) than both PREG CON and PREG TEA ($p<0.05$). Similarly, whole femur area and BMD of GROWTH CON were higher than both groups that experienced pregnancy though BMC was higher in the GROWTH CON group compared to PREG CON but not PREG TEA ($p<0.05$). For L4, GROWTH CON group was higher ($p<0.05$) for BV/TV, Tb.N and Ct.Th and lower for Tb.Sp compared to both pregnancy groups though PREG TEA had higher BV/TV, Tb.N and lower Tb.Sp than the PREG CON and suggests a benefit to L4 structure ($p<0.05$). Tb.Th was higher ($p<0.05$) in the GROWTH CON versus PREG CON group while PREG TEA did not differ from either group. BMC and BMD of whole L4 were higher ($p<0.05$) in GROWTH CON group compared to both pregnancy groups while area did not differ among groups. Overall, RR tea supported L4 structure following pregnancy and lactation but did not result in similar outcomes at the femur or L4 compared to the non-pregnant control.

Spatio-temporal and 3D imaging analysis of the initial stages of bone marrow formation *Emilio Hara[1], Tsz Long Chu[2], Andrei Chagin[2]. [1]Okayama University, Japan. [2]Karolinska Institutet, Sweden

The cell-cell and cell-matrix interactions are determinant factors in the formation and maintenance of the bone and bone marrow. In an attempt to understand these interactions, it is first necessary to identify the types of cells involved in these processes. For this purpose, we herein performed a spatiotemporal analysis of the first steps of bone formation during the secondary ossification center (SOC). Mouse femur epiphyses were collected at different developmental stages, and the ultrastructure of initially formed minerals was analyzed by scanning electron microscope (SEM), and scanning transmission electron microscope with energy-dispersive x-ray spectroscopy (STEM-EDS). For analysis of cellular components and distribution, we performed immunostaining, OMIC analysis, and tissue-clearing-based 3-dimensional imaging. This approach revealed complex architectures of apatite crystals during the cartilage-to-bone and bone-to-bone marrow transitions. Furthermore, several types of cells related to cartilage matrix degradation/turnover, and newly formed bone and bone marrow were identified and spatially characterized in tissue-cleared 3D images. These results provide important insights into mechanisms underlying the initial steps of osteogenesis within the SOC. Future studies are necessary to clarify their specific roles, and their interactions during these stages.

Finite Element Analysis of Regenerated Digit Bone *Kevin Hoffseth[1], Mimi Sammarco[2]. [1]Louisiana State University, United States. [2]Tulane University, United States

Purpose: Improving our understanding of how bone regeneration affects structure and mechanical performance at organ and microstructural levels is critical given the vital role of bone in human health. For this purpose, the mouse P3 digit regeneration process has been valuable in studying fundamental mechanisms underlying bone regeneration and healing and their connections to aging. This work details leveraging of µCT to finite element (FE) pipeline for improved analysis of regenerated bone structural quality and mechanical response, specifically the development of a FE-based approach to analyze the mouse P3 digit bone.Methods: Three-dimensional reconstruction of the digit bone is performed using new open-source image processing tools to convert CT images into a three-dimensional, volumetric model [1]. Calibrated µCT scan values and densiometric relationships are used to calculate spatially distinct Young's modulus values in the digit bone [2]. Custom programming scripts process the critical differences in regenerated bone morphology and assign spatially distinct Young's modulus values and create high resolution three-dimensional, volumetric finite element meshes, using 8 node hexahedral elements, implemented as linear elastic and isotropic, and solved in ABAQUS software. The proximal joint end was constrained from displacement and rotation, and distal tip subjected to vertical load for stress analysis, approximating a cantilever beam.Results: Initial results capture the difference in structure and response between uninjured and regenerated bone and effect of structure on potential damage initiation, in particular stress concentrations. Stress analysis results for a representative example of a regenerated digit bone may be seen in Figure 1.Conclusions: Morphologically accurate three-dimensional FE models of regenerated and uninjured mouse P3 digit bone built from µCT data demonstrate the ability to comparatively predict mechanical quality and identify possible sites of failure through stress concentrations. The expected outcome of this ongoing work project is further advancement of our ability to evaluate and predict the structure and mechanical response of regenerated bone, and enable more powerful evaluation of regeneration treatments.References:Hoffseth KF, et al., Bone. 2021;144:115776.Hoffseth KF, et al., J Biomech. 2022;143:111271.

The contribution of bone structure to sex-specific associations between femoral neck bone mineral density and strength *Karl Jepsen[1], ERIN BIGELOW[2], Robert Goulet[3], Bonnie Nolan[1], Michael Casden[1], Kathryn Kennedy[1], Samatha Hertz[1], Chandan Kadur[1], Gregory Clines[1], Aleda Leis[1], Carrie Karvonen-Gutierrez[4], Todd Bredbenner[5]. [1]University of Michigan, United States. [2]UNIVERSITY OF MICHIGAN, United States. [3]Michigan Medicine, University of Michigan, United States. [4], United States. [5]University of Colorado Colorado Springs, United States

Hip bone mineral density (BMD) is widely used to identify women and men with increased risk of fracturing. Low femoral neck (FN) BMD is an indicator of low strength, but this association has an unresolved sex-specific difference with men showing stronger proximal femurs for a given BMD compared to women. We used validated pseudoDXA images generated from high resolution nanoComputed Tomography (nanoCT) volumes to test how associations among bone structure, BMD, and strength vary by sex. Cadaveric proximal femurs from White female (n=51; 24-89+ years) and male (n=44; 18-89 years) donors were imaged and loaded in a sideways fall configuration to assess strength. Validated neural networks segmented bone from background and cortical from trabecular regions. A validated protocol for generating pseudoDXA images from the nanoCT images was used to generate pseudoDXA BMD, BMC, and area.Strength correlated significantly with BMD for females ($R2=0.61$, $p<0.001$) and males ($R2=0.44$, $p<0.001$) (Fig 1A). The y-intercept differed between sexes ($p<0.001$, ANCOVA); male proximal femurs were 1,059 N stronger than females for a given BMD. In contrast, strength correlated with BMC for females ($R2=0.57$, $p<0.001$) and males ($R2=0.49$, $p<0.001$), but with no difference in the slope ($p=0.69$) or y-intercept ($p=0.08$). Testing bone size-based normalizations found that normalizing BMC by femoral neck width, average total cross-sectional area, and total volume all showed significantly different y-intercepts ($p<0.001$, ANCOVA) suggesting bone-size normalizations led to the sex-difference in the BMD-strength association. We conducted linear regressions across the range of external bone sizes to test if the bone structures giving rise to BMC differ by sex (Fig 1B). A regression of % cortical bone against BMC showed that variation in BMC reflects different proportions of cortical and trabecular bone for men and women. For women, lower values of BMC reflect greater changes in cortical bone and a 50:50 mix of cortical and trabecular bone. For men, the associations were reversed such that lower values of BMC reflected greater changes in trabecular bone than in cortical bone. Thus, the proximal femurs of women are not smaller versions of male proximal femurs but are constructed

in fundamentally different manners. Given the reliance on BMD, it is critical to resolve discrepancies in the associations among BMD, strength, and underlying bone structures so fracture risk prediction is unbiased.

MRI-Based Finite Element Modeling of The Proximal Femur Discriminates Between Patients with and without Hip Fractures *Nada Kamona[1], Brandon Jones[1], Emily Tu[2], Iman Fathali[2], Gregory Chang[3], Chamith Rajapakse[4]. [1]Department of Radiology, Department of Bioengineering, University of Pennsylvania, United States. [2]Department of Radiology, University of Pennsylvania, United States. [3]Department of Radiology, New York University, United States. [4]Department of Radiology, Department of Orthopaedic Surgery, University of Pennsylvania, United States

Purpose: Deterioration of trabecular connectivity and thinning of cortical bone are important determinants of bone health because bone microarchitecture contributes substantially to bone fragility.1 Using finite-element analysis (FEA) applied to magnetic resonance (MR) images, we can directly simulate patient-specific bone biomechanics in vivo by reconstructing the 3D morphology of bone. Our goal was to assess bone strength of hip fracture patients using high-resolution MR images of the proximal femur.Methods: Subjects with (n=13) and without (n=13) hip fractures were recruited: 18 females, age 56+/-11.9 yo, BMI 22.7+/-4.0 kg/m2. Fracture and non-fracture groups were matched based on age, height, and weight. Subjects were imaged at the proximal femur with 3T MRI using a spoiled gradient echo sequence, with in-plane resolution of 234x234 ?m and a slice thickness of 1.5 mm2,3. Proximal femur images were manually segmented, and voxel values were inverted and scaled to create bone volume fraction maps, such that bone marrow and bone had values of 0% and 100%, respectively. A custom FEA model was used to simulate patient-specific sideways-fall configuration to mimic the most common direction of hip fracture injuries4. Linear and nonlinear FEA were utilized to estimate whole-bone stiffness (kN/mm) and failure load (kN/mm), respectively4,5. DXA-derived T scores of the total hip and spine were measured for all subjects. Differences between fracture and non-fracture patients were assessed using parametric two-sided t test or nonparametric Wilcoxon signed rank test. Results: An example high-resolution MR image for a fracture patient and the matched control is shown in Figure 1A. Patients with fractures had significantly lower estimated stiffness (P=0.002) and failure load (P=0.007) when compared to matched controls (Figure 1B). On the contrary, total hip T score was not different between fracture and non-fracture groups (P=0.243), while spine T score was erroneously higher in the fracture group (P=0.045). Estimated stiffness and failure load were highly correlated (R2=0.917, P<0.0001, Figure 1C). Neither total hip nor spine T scores were correlated with estimated mechanical properties. Conclusions: FEA applied to high-resolution MR images of the proximal femur can estimate bone mechanical competence, discriminating between hip fracture patients and non-fracture subjects. Bone strength may provide additional information of bone health that is not captured by DXA alone.

Trabecular but Not Cortical Bone Responded Similarly to Voluntary Wheel Running in Ovariectomized Mice at Different Skeletal Sites *Dawson B. Kays[1], Jenalyn L. Yumol[1], Ahmad Mohammad[1], Jacob Sweezey-Munroe[1], Rebecca E.K. MacPherson[1], Wendy E. Ward[1]. [1]Brock University , Canada

Mechanical loading is a known stimulus of bone tissue in rodent models but whether long bones respond similarly to exercise is unclear. Knowing this will help inform which long bone should be studied in response to an exercise intervention. The study objective determined if femur and tibia respond similarly to voluntary wheel running (VWR) after ovariectomy (OVX). 24-week-old C57BL6/J mice underwent sham surgery (SHAM; n=20) or OVX (n=20). After 4 weeks, mice were assigned to SHAM (n=10), SHAM+VWR (n=10), OVX (n=10), or OVX+VWR (n=10) for 8 weeks (endpoint). SHAM ran a longer distance compared to OVX (total distance 65+/-9 km versus 29+/-37 km, p<0.05). At endpoint, distal and midpoint regions of femur and at proximal and midpoint regions of tibia were measured using micro computed tomography (SkyScan 1176). Bone mineral density (BMD) of whole femur and tibia were measured using dual energy X-ray absorptiometry (Scintica InSiGHT). As expected, there was a main effect of OVX: distal femur had lower cortical area fraction (Ct.Ar/Tt.Ar) and cortical thickness (Ct.Th), as well as higher trabecular separation (Tb.Sp); femur and tibia midpoint had lower Ct.Ar/Tt.Ar and Ct.Th; and proximal tibia had lower Ct.Ar/Tt.Ar, Ct.Th, bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th) and higher Tb.Sp compared to SHAM (p<0.05). Whole femur but not tibia BMD was lower (p<0.05) with OVX versus SHAM. To assess whether femurs and tibias responded similarly to VWR, trabecular structure at distal femur and proximal tibia were compared. Also, cortical structure was assessed at these sites, and at femur and tibia midpoint. There was a main effect of VWR at both the distal femur and proximal tibia with higher BV/TV and Tb.N and lower Tb.Sp (p<0.05). There was an interaction (p<0.05) for VWR and estrogen status for Ct.Ar/Tt.Ar and Ct.Th at proximal tibia but not at distal femur. Regardless of VWR, OVX had lower (p<0.05) Ct.Ar/Tt.Ar and Ct.Th compared to SHAM. However, VWR resulted in higher (p<0.05) Ct.Ar/Tt.Ar and Ct.Th in SHAM groups only. At femur but not tibia midpoint, there was a main effect of VWR (higher Ct.Ar/Tt.Ar and Ct.Th, p<0.05). In conclusion, trabecular but not cortical bone responded similarly to exercise when comparing femurs and tibias. These findings support studying multiple skeletal sites to assess the effect of VWR. Findings also suggest that minimal VWR is needed to support bone health following ovariectomy.

Changes in the Microstructural and Mechanical Properties in theMedial Condyle of Human Distal Femur in Advanced Osteoarthritis *Kwangkyoun Kim[1.] [1]Konyang university, college of medicine, Republic of Korea

Objectives: The purpose of this study is to analyze and compare the micro-structural and mechanical properties of subchondral trabecular bone of non-osteoarthritic and osteoarthritic distal femur using micro-images based on finite element analysis.Materials and Methods: Twenty distal femurs were harvested from 10 cadavers. The subchondral trabeculae were obtained from the middle of the articular surface of the medial femoral condyle of distal femurs. A total of 20 specimens were scanned using the micro-CT system. Micro-CT images were converted to micro-finite element model using the mesh technique, and micro-finite element analysis was then performed for assessment of the mechanical properties. Results: According to the results, trabecular bone of osteoarthritic distal femur showed a decrease in trabecular thickness, bone volume fraction, structure model index, and yield stress and an increase in trabecular separation and structure model index.Conclusions: Results of bone morphometry index and strength showed greater deterioration of microstructure and decreased mechanical strength in subchondral trabeculae of the osteoarthritic group.

Bone Stress Injury Associates with Increased Cortical Porosity at a Common Fracture Site *Lysanne Michels[1.] Jacob Trend[1.] Theo Hornsey[1.] Philipp Schneider[1.] Andrew Pitsillides[2.] Julie Greeves[3.] Thomas O'Leary[3.] Claire Clarkin[1.] [1]University of Southampton, United Kingdom [2]Royal Veterinary College, United Kingdom [3]Army Health and Performance Research, United Kingdom

IntroductionWomen experience more bone stress injuries (BSIs) in the military than men [1-2], often located along the posterior-medial aspect [3], of which the pathogenesis remains poorly understood. Cortical porosity includes vascular canals and is a critical predictor of bone strength [4]; we therefore aimed to analyse whether differences in the cortical vascular canals associate with bone stress injuries.MethodsHR-pQCT scans (61 ?m) were taken at the tibial diaphysis, a common BSI site, of injured women (n = 5) and sex- and age-matched non-injured controls (n = 6) at the start of the 44-week Officer Commissioning Course in Sandhurst, UK. The volume and diameter of cortical vascular canals were extracted from anterior, medial, lateral, and posterior regions in ImageJ as these are exposed to different strains [3, 5]. In ORS Dragonfly, Distance Mapping was used to divide canals into endosteal (0-40% from the endosteal surface), embedded (41-60%), and periosteal (61-100%) as these are exposed to different blood flows [6].ResultsNo differences between injured and non-injured women were observed when canals or regions were pooled. However, upon regionalisation injured women exhibited larger periosteal canals (61-80% from the endosteal surface) in the posterior (0.338 +/- 0.462 mm3) compared to medial (0.054 +/- 0.040 mm3) and lateral (0.019 +/- 0.014 mm3) regions. These were also wider in the posterior (0.186 +/- 0.048 mm) than lateral region (0.136 +/- 0.010 mm). In contrast, controls exhibited no spatial variation in canal size (fig. 1). As such, posterior periosteal canals were larger in injured than non-injured women (0.048 +/- 0.051 mm3; p = 0.042). DiscussionIncreased canal size in the posterior region could contribute to BSIs originating here, with higher cortical porosity reducing bone strength thus elevating fracture risk [4-5]. These pre-injury differences may point towards a different distribution of or sensitivity to strain linking to fatigue damage [4-5], and can be utilised to identify individuals at risk of bone stress injury thereby allowing for the development of targeted preventions.References[1] Wentz et al. 2011. Automating quantitative analysis of peri-articular bone microarchitecture in HR-pQCT knee images using deep learning and atlas-based segmentation *Nathan Neeteson[2.] Steven Boyd[2.] [2]University of Calgary, [2]University of Calgary, Canada

High-resolution peripheral quantitative computed tomography (HR-pQCT) is an in-vivo imaging tool allowing direct quantification of bone microarchitecture. However, peri-articular analysis of HR-pQCT knee images requires accurate semantic segmentations of the subchondral bone plate and trabecular bone and the articular contact surface regions of interest (ROIs) on the tibia and femur. Here, we propose a fully automated solution using deep learning for bone segmentation and atlas-based segmentation for contact surface ROI definition.Bone segmentations are generated by a neural network (UNETR) that was pre-trained on 2601 manually segmented HR-pQCT radius and tibia images and retrained on 38 expert-segmented HR-pQCT knee images. Segmentation model performance is evaluated based on the Dice similarity coefficient (DSC) of the ground truth and predicted subchondral bone plate segmentations, calculated using five-fold cross-validation. Articular contact surface ROIs are generated using atlas-based segmentation. A femur or tibia image is downsampled and smoothed then deformably registered to a fixed reference image using a multiscale diffeomorphic Demon's algorithm. The ROI mask is then deformably transformed from the fixed reference to define the contact surface ROIs in the moving image. ROI definition performance is evaluated based on DSC between ground truth and registered ROI masks. The final peri-articular ROIs can then be computed via the intersection of the contact surface ROIs with the bone segmentation, and these ROIs can be used for regional microarchitectural analysis.The bone segmentation model achieves a mean validation set DSC of 0.94 for subchondral bone plate, indicating excellent agreement between the predicted and ground truth bone segmentations. Sample ground truth and predicted segmentations are shown in figure 1. The deformable registration procedure produces registered articular contact surface ROIs with an average DSC of 0.85 (min: 0.75, max: 0.91). Generation of an average atlas from the reference images is ongoing, as is the development of a pipeline for combining the contact surface ROIs and bone segmentations to complete automation of microarchitectural analysis.This work demonstrates that bone segmentation and contact surface ROI definition can both be accurately automated, using deep learning and atlas-based segmentation, respectively. This will allow full automation of peri-articular analysis of knee HR-pQCT images.

Chromosomal sex (XX vs XY) contributes to bone and muscle mass independently of the gonadal sex (ovaries vs testis) in the 4 core genotype mouse model. *Lilian Plotkin[1.] Matthew Arnett[2.] Dyann Segvich[3.] Padmini Deosthale[1.] Chiebuka Okpara[4.] JULIAN BALANTA-MELO[5.] FABRIZIO PIN[6.] Joseph Wallace[7.] [1]Indiana University School of Medicine, United States [2]I, United States [3]Indiana University-Purdue University Indianapolis, United States [4]Lehigh University, United States [5]Universidad del Valle, Colombia [6], United States [7]Indiana University Purdue University Indianapolis (IUPUI), United States

Vertebrate sexual dimorphism is ascribed to the presence of testis or ovaries, and, hence, to gonad-specific hormone production. Sex differences also stem from the presence of sex chromosomes (XX or XY). To tease out the contribution of chromosome (CS) from gonad (GS) sex, the Sry gene that dictates testis formation was either deleted in XY mice, resulting in XYF mice with ovaries or overexpressed in XX mice, resulting in XXM mice with testis. These mice, together with XY males (M) and XX females (F) form the 4core genotype (FCG) model. It has been shown that levels of estrogen in XXF/XYF and androgen in XXM/XYM are similar. We now show that the musculoskeletal phenotype of 2 and 4 month (m) FCG mice depends on both GS and CS. Mice were scanned for DXA, blood/tissues were

collected, and bones were tested by µCT and 3-point bending. GS/CS effects were assessed by 2-way ANOVA (Tukey post-hoc test). GS influenced body weight (BW), and total/femur/spine BMD at 2m, and BW and total/femur BMD at 4m, all lower in gonadal females (Table1). A GS-CS interaction was found in 2m mouse spine BMD, which was lower in XYF than XYM, but similar in XXF and XXM mice. At 4m, XY mice show lower BW and BMD at the 3 sites than XX mice, whereas % lean mass was higher in XYM and XYF than the respective XX mice, and % fat mass was lower in XYM vs XXM, indicating CS effects (Table2). Skeletal muscle weights were lower in gonadal females (XXF/XYF) than in males (XXM/XYM) at 2m (Table3) whereas soleus muscle weight was higher in XYM than in XXM mice and no different in females. Fewer differences were found at 4m, with a CS-dependent effect in QC weight (higher in XXM than in XYM). µCT showed GS and CS contribution to structural parameters and TMD in femur mid-diaphysis -lower in XYF vs XXF, no different in males- whereas only GS affected marrow cavity and total tissue area and MOI at 4m (Table4). Bone mechanical properties were overall lower in gonadal females (Table5). CS only affected ultimate force - lower in XYF vs XXF, no different in males. GS affected all distal femur trabecular structural parameters, which were lower in gonadal females, but only partially L5 vertebrae (Table4). L5 tissue mineral density TMD depended on CS and was higher only in XXF vs XYF. Finally, GS and CS also affected serum chemokine levels, which might explain changes in bone and muscle cell function (Table6). Thus, while GS has a major role, CS is a so far unrecognized contributor to bone/muscle mass and bone strength.

Quantification of the Photon Counting CT Reproducibility And Its Implication For Detecting Bone Remodeling *Jilmen Quintiens[1,] Harry van Lenthe[2,] Walter Coudyzer[3.] [1]Department of Mechanical Engineering, KU Leuven, Belgium. [2]KU Leuven, Belgium. [3]University Hospital Gasthuisberg, Belgium

For the quantification of localized bone strength and bone changes, volumetric methods such as quantitative CT are to be preferred over conventional techniques such as DXA. This due to DXA being a two-dimensional technique, which is dependent on body frame [1]. However, the low resolution of conventional clinical CT limits direct implementation in health care. Photon Counting CT (PCCT) shows potential to overcome this limitation thanks to its higher resolution and better image contrast. The aim of this study was to quantify the reproducibility of PCCT and determine the least-detectable change in volumetric bone density.Using PCCT (NAEOTOM Alpha, Siemens Healthineers), eighth cadaveric wrists were scanned twice with repositioning. For each wrist, the eight carpal bones were delineated. Images were registered onto each other and the difference image was calculated by voxel-wise subtraction. In parallel, a phantom was scanned and a linear relation was fitted, expressing volumetric bone density as a function of Hounsfield Unit (HU). Bone remodeling was defined as all voxels in the difference image that surpassed a predefined threshold and that were part of a cluster of at least 5 voxels.Averaged over all samples, estimated mean intensity difference is 1.75 HU, and estimated standard deviation 142 HU. For a threshold of 250 mgHA/cm³, the total amount of falsely detected remodeling amounts to 0.31% (formation 0.14% +- 0.17%; resorption 0.17% +- 0.39%; Fig.1). This is an acceptable error, hence differences above this threshold are likely to be physiological in nature.Our results compare well to HRpQCT. In a similar ex vivo study with HRpQCT, Christen et al. [2] reported 0.4% remodeling for a threshold of 225 mgHA/cm³. Using the same threshold in an in vivo analysis, remodeling increased to > 5%, due to motion artifacts. For in vivo analyses we hypothesize that PCCT may outperform HRpQCT because of the shorter acquisition time which limits these artifacts.In conclusion, PCCT shows an excellent reproducibility when quantifying volumetric bone density and results are comparable to HRpQCT. This study considers bone remodeling based on image intensity only; however, also voxel size plays an important role, which could favor HRpQCT. In future studies we will 1) repeat the analysis with in vivo measurements and 2) use PCCT for a follow-up study in patients.[1] Alawi et al., Cureus 13(2): e13261, 2021.[2] Christen et al., PLoS One 13: e0191369, 2018.

Type 2 Diabetes Affects Advanced Glycation End-Products and Indentation Properties in Human Bone *Taraneh Rezaee[1,] Rachana Vaidya[2,] Leland O. Barret[3,] Zackery Joseph Silva[3,] Christian Leonarde Ray[4,] Brooke Lynn DeSimone[4,] Lamya Karim[5.] [1]1.Department of Bioengineering, University of Massachusetts Dartmouth 2. Department of Biomedical Engineering, City College of New York of the City University of New York, United States. [2]washington university in st louis , . [3]1. Department of Bioengineering, University of Massachusetts Dartmouth, United States. [4]1Department of Bioengineering, University of Massachusetts Dartmouth, United States. [5]University of Massachusetts Dartmouth, United States

Type 2 diabetic (T2D) patients have 3 times higher fracture risk than non-diabetics [1] despite having normal or high bone mineral density, and this risk may be due to having poor bone quality. Bone quality can be impacted by the accumulation of collagen crosslinks known as advanced glycation end-products (AGEs) that form from non-enzymatic glycation [2]. Our goal was to investigate how tissue-level mechanical behavior of human cortical beams are impacted by altered AGEs in T2D. We hypothesized that T2D bone will have more AGEs and weakened indentation properties compared to non-diabetic bone.We obtained 120 transverse and longitudinal cortical beams from 4 human cadaveric donors (young T2D, young non-diabetic, old T2D, old non-diabetic). Cyclic reference point indentation (cRPI) tests were conducted on all samples using a Biodent system at 6 N, 2 Hz, for 20 cycles. Five indentations were made on the periosteal surface at the proximal end of each beam (~1 mm intervals). Total fluorescent AGEs were measured by a fluorometric assay in all beams and the AGE pentosidine was measured by high performance liquid chromatography in a subset of longitudinal beams (n=48).Young T2D bone had higher AGEs than young non-diabetic in longitudinal beams, with a similar trend in transverse beams. Pentosidine was higher in T2D young vs non-diabetic young beams. These trends were not seen in old donors. cRPI-assessed ID, TID and Avg ED were higher in young T2D vs young non-diabetic bone within longitudinal beams, but there were no differences in the older groups (Table 1). ID, TID, IDI, and Avg ED were higher while Avg US and Avg LS were lower in young T2D bone vs young non-diabetic bone within transverse beams (Table 1). Among older transverse beams, CID was lower in diabetic vs non-diabetic, but no other variables were significantly different. T2D bone had more glycation content than non-diabetic bone as predicted, but this was only observed in young donors. It is possible that T2D has a greater impact in young bone but not in old bone where donors may have faced other more severe health issues such as osteoporosis that have a greater impact on bone health than T2D. Correspondingly, young T2D bone experienced deeper indentation distances than non-diabetic bone as well as reduced stiffness. These results show that young T2D bone with higher AGEs had poor tissue-level mechanical properties.References: [1] Skelly AH, Nursing Clinics, 2006; [2] Tang, et al., Bone, 2007

Developing a "virtual bone biopsy" technique for determining total bone turnover in patients with chronic kidney disease *Saghi Sadoughi[1], Lauren Go[1], Gabby Ramil[1], Aditya Subramanian[1], Po-hung Wu[2], Isra Saeed[1], Joachim H. Ix[3], Galateia Kazakia[1]. [1]University of California, San Francisco, United States, [2]University of California - San Francisco, , [3]University of California, San Diego, United States

Time-lapse HR-pQCT employs sequential scans over time to identify areas and rates of bone formation and resorption. This technique may be well suited to non-invasively measure bone turnover in patients with chronic kidney disease (CKD), who suffer from two extreme subtypes of bone disease: high and low turnover. Because blood biomarkers of bone turnover are unreliable in patients with CKD, the gold standard measure of bone turnover remains iliac crest biopsy. This procedure is invasive, expensive, and available at limited medical centers. Thus, non-invasive "virtual bone biopsy" that can reliably estimate bone turnover in patients with CKD and be measured repeatedly has the potential to revolutionize CKD bone care. The goal of this study was to develop a "virtual bone biopsy" to determine bone turnover in patients with CKD, and to evaluate the technique's sensitivity to measuring turnover over different time periods.Nine individuals with CKD on dialysis (4 women, 5 men; 59 +/- 18 years) were recruited. HR-pQCT scans were acquired on XtremeCT II at the radius and tibia. Patients were scanned at BL (n=9), 2-month FU (n=7), and 4-month FU (n=3). Of the 38 total scans, 5 radius scans were eliminated from analysis due to motion. BL and FU sets were registered using 3D registration and a voxel-wise density difference map was created. A two-step filter approach was then applied to reduce artifacts. Outcome metrics Bone Formation Fraction (BFF) and Bone Resorption Fraction (BRF) were calculated by dividing the number of formation or resorption voxels by BL total bone voxels. Total Bone Turnover (TBT) was calculated as the sum of BFF and BRF (Fig1A-B). Precision metrics were calculated using scan-rescan data in 20 healthy volunteers (9 women, 11 men; 53 +/- 18 years). Two-month TBT (mean +/- SD) was 16.5 +/- 5.9% and 9.9 +/- 4.3% at the radius and tibia, respectively. Four-month TBT was 30.3% (single set) and 17.7+/-3.9% at the radius and tibia, respectively. The 4-month TBT values were 2 to 3 times greater than the LSC at the radius and tibia of 12.1% and 8.2%, respectively, found in our precision study (Fig1C-D).We found that although mean TBT at 2-month FU was greater than LSC at both radius and tibia, not all individual patients had TBT greater than LSC. At 4-month FU, TBT in all patients was greater than LSC, demonstrating adequate sensitivity to detect changes over a 4-month period in patients with CKD. These promising results will be validated against surgical biopsy.

MRI-Based Finite Element Modeling Approach to Quantify the Relationship between Femoral Geometry and Atypical Femoral Fracture *Ashkan Sedigh[1], Brandon Jones[2], Nada Kamona[2], Christiana Cottrell[2], Rasleen Grewal[2], David Baretto[2], Achala Kankanamge[2], Jianna Kim[2], Elaine Li[2], Kevin Li[1], Makayla Clark[2], Ganen Chinniah[2], Caroline Paik[2], Reva Bhatt[2], Ryan Shams[2], Maegan Sojan[2], Chamith Rajapakse[2], Ani Ural[1]. [1]Villanova University, United States, [2]University of Pennsylvania, United States

Atypical femoral fracture (AFF) that occurs at the subtrochanteric or midshaft region of the femur has been associated with long-term bisphosphonate use. The current clinical population-based studies have not been able to explain the underlying mechanisms of AFF. Moreover, femoral geometrical properties that increase AFF risk have not been conclusively identified. Thus, this study aims to develop a novel MRI-based finite element (FE) modeling approach to identify the relationship between femoral geometry and AFF.Five female human cadaveric femurs were scanned via magnetic resonance imaging (MRI) at an isotropic resolution of 341 ?m. The images were segmented and processed using Simpleware ScanIP to generate FE meshes (~700k elements). The meshes were imported into the FE analysis software, Abaqus, and were subjected to stance loading (Fig. 1A). The fracture process was modeled by the cohesive extended finite element method (XFEM). Homogeneous material properties were assigned to the models based on the literature. The load-displacement data were extracted to assess the influence of femur geometrical properties (neck shaft angle, neck variation angle, neck length, femur neck thickness, and midshaft diameter) on femoral mechanical properties.The simulation results showed that the stiffness, peak load, and displacement at the peak load corresponding to crack formation at the AFF site correlate with the shaft diameter (R=0.79, 0.69, -0.95, respectively) (Fig. 1B). No statistically significant relationships were observed between stiffness, peak load, displacement at the peak load, and other geometrical parameters.This study established a modeling approach incorporating MRI and fracture mechanics-based FE modeling for evaluating the influence of femoral geometrical properties on the mechanical response at the AFF site. The variation in mechanical properties with femoral geometry incorporating the same material properties indicates the significant contribution of femur geometry to the fracture resistance at AFF sites. The modeling process developed here can be adapted to incorporate additional MRI-based geometrical measurements, such as bowing angle, and parameters, such as bone volume fraction, cortical porosity, and collagen fraction. As a result, MRI-based FE models provide a promising new approach for the noninvasive assessment of the femur's geometrical and material properties and identify the multifactorial determinants of AFF.

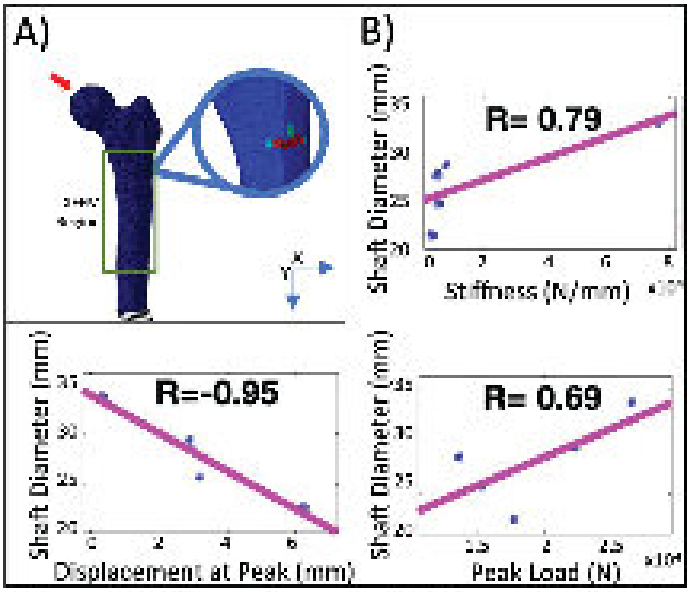

Figure 1. A) Femur FE model with the applied load (red arrow) and crack initiation at the AP1 site. B) Variation of mechanical properties of femur with shaft diameter showing Pearson correlation coefficients.

Investigation of human cortical bone quality in osteoporosis with and without type 2 diabetes *Praveer Sihota[1], Saroj Kumar[2], Piyush Uniyal[2], Ram Naresh Yadav[2], Vandana Dhiman[3], Ruban Dhaliwal[4], Deepak Neradi[3], Shailesh Karn[3], Sidhartha Sharma[3], Sameer Aggarwal[3], Vijay G Goni[3], Vishwajeet Mehandia[2], Deepak Vashishth[5], Bjoern Busse[1], Sanjay Kumar Bhadada[6], Navin Kumar[2]. [1]University Medical Center Hamburg-Eppendorf, Germany [2]IIT Ropar, India. [3]PGIMER Chandigarh, India. [4]State University of New York Upstate Medical University, . [5]Rensselaer Polytechnic Institute, United States. [6]PGIMER, chandigarh, India, India

Purpose: Individuals with type 2 diabetes mellitus (T2D) are at a higher risk of hip fractures, even with normal to high bone mineral density (BMD). To better understand the factors contributing to this increased risk, we investigated the role of multi-scale cortical bone quality parameters in hip fragility fractures in individuals with T2D. Although T2D is known to cause alterations in cortical bone quality, the specific factors underlying the increased fracture risk remain unclear. Thus, our research aimed to determine if cortical porosity, material properties, or glycation content are independently associated with increased susceptibility to hip fractures in T2D.Method: This cross-sectional observational study investigated the multi-scale bone quality parameters in individuals with type 2 diabetes (T2D) and non-diabetic individuals who underwent hip replacement surgery for their first fragility hip fracture, all recruited from Northern India. We collected inferomedial femoral neck bone tissue specimens and measured cortical porosity using high-resolution micro CT, biomechanical properties using uniaxial compression and nanoindentation, local bone composition with FTIR, gravimetric mineral: matrix ratio, and bone glycation using the fAGE assay. Results: In the study, there was no significant difference in areal BMD between the T2D and non-diabetic groups, but cortical porosity was higher in the T2D group. Biomechanical properties, including ultimate strength, ultimate strain, post-yield strain, toughness, and post-yield energy, were significantly lower in the T2D group. Nanoindentation properties were not different between the groups. The T2D group had a lower gravimetric mineral: matrix ratio, higher FTIR parameters related to glycation content, and higher levels of fAGEs. ANCOVA analysis suggested that the increased cortical porosity explained the decreased ultimate stress observed in the T2D group. Moreover, the higher glycation content in the bone matrix was negatively associated with the nanoindentation-derived E/H ratio, indicating that the bone from T2D patients had reduced plastic deformation.Conclusions: The findings suggest that the increased cortical porosity in T2D individuals may lead to reduced bone strength, while the presence of elevated levels of fAGEs in the bone matrix may contribute to decreased bone deformation and energy absorption, making the bone more brittle and prone to fracture.

3D Cortical Bone Mineral Density Distribution is influenced by genetics and gene-by-diet interactions in mice. *Semahat Serra Ucer Ozgurel[1], Joseph Sheeran[2], Corinne Metzger[4], Matthew Allen[4], James Fleet[1]. [1]University of Texas at Austin, United States. [2]California Institute of Technology, United States. [4]Indiana University School of Medicine, . [4]Indiana University School of Medicine, United States

The heterogeneity and degree of bone mineralization impact the material properties of bone. Tissue-level heterogeneity can be assessed with a bone mineral density distribution (BMDD) determined from 2D-histological sections of bone biopsies using backscatter electron microscopy. Recently, several groups have explored the use of BMDD from 3D-micro-computed tomography (?CT) scans. We further evaluated the ?CT-based BMDD of cortical bone in preclinical mouse models with genetic modifications or treatments that affect bone. In Vitamin D Receptor KO mice, BMDD was shifted to lower density depicted by lower mean degree of mineralization of bone (MDMB), and a lower distribution variance (?2) (n=5-12/genotype) due to the disruption of calcium metabolism. Intermittent PTH (1-34) treatment (100 ng/g/day, 4-wks, n=6-7) also shifted the BMDD to lower a MDMB but with no changes in ?2, indicating that the new bone formed had not yet fully mineralized. MDMB was also lower in 86-wk vs 24-wk old mice, reflecting an imbalance in bone remodeling towards more resorption. In addition, mice with adenine-induced chronic kidney disease (CKD) had decreased MDMB with lower ?2 compared to controls, in agreement with impaired mineralization and longer mineralization lag time observed in CKD patients. We next assessed whether BMDD parameters correlated with material properties parameters from Reference Point Indentation (RPI). In a genetically diverse panel of 11 inbred strains (12 wk old males), we found significant correlations between RPI and BMDD variables, e.g., MDMB and unloading slope, an indicator of material stiffness (r= 0.57, p<.0001, n=162). MDMB from aging/CKD mice also correlated with stiffness from 4-point bending analysis (r=0.63, p<.001, n=25). BMDD parameters (including MDMB and ?2) were significantly different across the panel of 11 inbred strains (n=13-16/strain, see figure), indicating a significant impact of genetics on BMDD. In inbred strains fed 0.25% or 0.5% Ca diets from weaning (n=5-8/line/diet), the BMDD of some, but not all lines were modified by diet, indicating the existence of gene-by-diet (GxD) interactions. Our results show that the 3D ?CT-based BMDD is a useful tool that reflects the material properties of bone and that it can be used to evaluate the impact treatments and genetics on bone. The genetic and GxD effects we saw on BMDD lay the groundwork for a discovery-focused initiative to identify novel genes controlling bone mineralization.

Impact Microindentation Measures of Bone Quality is Strongly Correlated with Whole Bone Strength at the Hip, Wrist and Lumbar Spine. *Rachana Vaidya[1], Simon Tang[2], Babak Jahani[3], James Jin[4]. [1]University of Massachusetts Dartmouth, , [2]Washington University in St Louis, United States, [3]Washington University in St.Louis, United States, [4]Washington University in St.Louis , United States

Introduction: Post-menopausal women experience a significant incidence of hip, wrist, and spine fractures, with two-thirds of all fractures occurring in women without osteoporosis, as determined by DXA. While BMD is used to diagnose osteoporosis and predict fracture risk, it does not consider variations in bone composition and structure that affect bone strength. Impact microindentation (IMI) assesses bone quality at the tissue level and provides information beyond BMD. Our objective is to investigate the relationship between IMI, BMD, and bone strength in a cadaver study to better understand the factors contributing to bone strength and improve fracture risk prediction.Methods: We harvested femurs, radii, L4 vertebrae, and tibiae from human cadavers (mean age of 71+/-13 years). DXA measured BMD at different skeletal sites. IMI was performed at the FDA-approved tibia mid-diaphysis site and reported as a Bone score. We mechanically tested bones to calculate fracture force (N) as a measurement of bone strength. We evaluated tissue-level mechanical properties using 3-point bending tests and performed IMI measurements on regions outside the mid-span to reduce bone heterogeneity effects. We investigated the relationships between bone strength, BMD, and bone scores using Pearson's correlation and multivariate regression. Results: Our findings suggest that measuring bone quality using indentation at the tibia is predictive of bone strength at other skeletal sites. Tibia bone score shows higher correlation to bone strength than BMD at the femur (Fig1A) and radius (Fig2A). Adding the tibia bone score measurement to BMD, increases the correlation to bone strength by 20% at the femur (Fig1B) and 10% at the radius (Fig2B). At the spine, tibia bone scores show a strong correlation to bone strength, but not lumbar BMD, and combining the two does not significantly improve the correlation to bone strength(Fig1.3A,B). The beam bone scores were strongly correlated with key measures of material behavior, such as toughness and ultimate stress (Fig1.4). Our results suggest that incorporating measures of bone quality with impact microindentation can improve fracture risk evaluation, particularly in high-risk fracture sites. Significance: IMI provides additional information on bone quality and identifies individuals at increased risk of fractures, allowing for earlier interventions to prevent fractures.

Joint alignment angles and joint space width measured by EOS imaging for patients with an acute anterior cruciate ligament injury in the knee *Isabella Vandergaag[2], Richard Walker[2], Steven Boyd[2]. [2]University of Calgary, , [2]University of Calgary, Canada

The anterior cruciate ligament (ACL) is one of the most frequently injured ligaments among young, athletic individuals1. Many of these patients show early stages of osteoarthrosis (OA) at the 10-year mark following their injury2. Previous research suggests that anatomical factors, such as joint space width (JSW) and quadriceps angle (Q-angle), contribute to both ACL tear incidence and reoccurring injury. These anatomical factors may also contribute to worsening pain, motor functioning, and mental distress for patients during and post recovery3,4. However, there is limited investigation between these anatomical factors and effect on quality of life (QoL) outcomes during the immediate time following injury. Understanding the link between geometric factors and QoL could help develop interventions to prevent worsened clinical outcomes. The long-term purpose of this study is to identify whether JSW and Q-angle can predict the rate of QoL change following ACL injury in a longitudinal study, therefore we aim to determine the use of EOS imaging for measurement of these parameters.Our two cohorts included (1) uninjured individuals (N=30, 50% female) for reproducibility and repeatability of measurements of Q-angle and JSW, and (2) individuals who sustained an acute rupture of the ACL <6 weeks before imaging (N=41, 75% female). Q-angle and JSW was assessed for both populations with manual measurements, X-ray, and EOS Imaging. Wilcox statistical tests and Dunn tests compared the Q-angle and JSW between the two modalities and interrelationships were further explored by linear regression.The accuracy of Q-angle measurement from EOS imaging was confirmed in comparison to manual assessment in the uninjured cohort. Females had significantly higher Q-angle measured by both modalities. JSW assessed by EOS followed the same trends as measured by X-ray, although there was a bias for higher JSW by EOS. Furthermore, the EOS standing position, which is performed with the left leg unloaded, resulted in a significantly higher JSW measurement for uninjured participants in the left leg (Figure 1).We have established reproducibility of our measures of JSW and Q-angle and future work will establish the relationship of baseline anatomical factors to change in QoL measures to better understand their role in acute ACL injury.References1. Comparing Atypical Femoral Fractures with and without bisphosphonate treatment. A case series on patient and fracture characteristics and histological findings. *Georg Zdolsek[1], Hans Peter Bögl[2], Anna Fahlgren[3], Jörg Schilcher[4]. [1]Department of Orthopedic Surgery and Department of Biomedical and Clinical Sciences, Faculty of Health Science, Linköping University, Linköping, Sweden , Sweden, [2]Department of Orthopedic Surgery, Gävle Hospital, Gävle and Department of Biomedical and Clinical Sciences, Linköping University, Linköping, Sweden, Sweden, [3]Department of Biomedical and Clinical Sciences, Division of Cell Biology, Linköping Universi-ty, Linköping, Sweden, Sweden, [4]Department of Orthopedic Surgery and Department of Biomedical and Clinical Sciences, Faculty of Health Science, Linköping University, Linköping, Sweden and Wallenberg Centre for Molecular Medicine, Linköping University, Linköping, Sweden , Sweden

Introduction: Atypical femur fractures (AFF) are insufficiency fractures with a strong association to antiresorptive treatment (ART). Little is known about patients with AFF who are ART naive. We have investigated clinical background, radiological appearance, and histological findings at the fracture site in patients with and without ART to provide insights into the underlying fracture pathophysiology.Method: Between 2008-2021, 19 patients (>50 yrs), with surgically treated incomplete AFF underwent surgical resection of the stress fracture lesion during nailing. Of the 19 patients, 9 (5 women) had no reported exposure to ART (-ART group, mean age 69.6 years, SD 12.4 years) and 10 (9 women, mean age 77.4 years, SD 10.5) had ART treatment (+ART group) on average 6.7 years, (SD 5.1 years). Hematoxylin and eosin staining was performed in all cases to allow basic histological assessment and histomorphometric analyses.Results: The common etiology for AFF in the +ART group was long-term bisphosphonate treatment. There were different etiologies in the -ART group (Paget's disease of bone N=1, adynamic bone disease N=1, hypophosphatasia N=1, coxa vara N=1, extensive lateral bow N=1, heavy loading N=1, unspecified N=3). Fractures in the mid-shaft region, were more frequent in the +ART group (N=9) compared to -ART (N=6) and multiple cortical lesions were more common in the -ART group (N=4) compared to +ART (N=2). The bone volume fraction (BV/TV) was lower in the -ART group, mean 72.0% (SD 7.6) compared to the +ART group, mean 81.3% (SD 5.4), mean difference -9.3% (95% CI -15.6% to -2.9%). There was no difference in specific surface of bone (BS/TV), percentage of alive osteocytes, mean width of fracture gap or bone surface per bone volume

(BS/BV).After surgical fixation all but two patients where the osteosynthesis was removed healed uneventfully. One patient with Paget's disease of bone had avascular necrosis of the femoral head after treatment for infection.Discussion and conclusions: Most patients without ART had an underlying bone metabolic disease which most likely caused the insufficiency fracture. These findings are supported by differences in radiological and histological findings. For a successful orthopedic treatment of AFF-patients with and without ART, a high level of suspicion for underlying bone metabolic pathologies or biomechanical variations is necessary.

Fracture Healing Leads to Localized Structural Bone Loss Quantified using Void Space Analysis *Danielle Whittier[1], Matthias Walle[2], Charles Ledoux[3], Penny Atkins[1], Caitlyn Collins[4], Julia Holtmann[5], Matthias Zumstein[6], Patrik Christen[7], Kurt Lippuner[8], Ralph Müller[3]. [1]Institute for Biomechanics, ETH Zurich; Department of Osteoporosis, University Hospital of Bern, Switzerland, [2]ETH Zurich, , [3]Institute for Biomechanics, ETH Zurich, Switzerland, [4]Virginia Tech, United States, [5]Department of Orthopaedic Surgery and Traumatology, University Hospital of Bern, Switzerland, [6]Department of Orthopaedic Surgery and Traumatology, University Hospital of Bern; Sonnenhof Orthopaedics, Bern, Switzerland, Switzerland, [7]Institute for Information Systems, FHNW, Switzerland, [8]Department of Osteoporosis, University Hospital of Bern, Switzerland

High-resolution peripheral quantitative computed tomography (HR-pQCT) has shown rapid changes in bone mineral density (BMD), morphology, and biomechanical properties at the distal radius during fracture healing. However, patient outcomes in terms of BMD are highly variable, suggesting that changes in bone microarchitecture may also play a role in patient-specific recovery and long-term bone strength. This study uses void space analysis to identify regions of adverse localized structural bone loss during fracture healing.Twenty-six patients (21 female, 5 male; aged 18-79 years) with conservatively-treated distal radius fractures were scanned using HR-pQCT (XtremeCT II, 61 µm) at 6 timepoints post-fracture (weeks 1, 3, 5, 12, 26, and 52). The common scan region across timepoints was determine using 3D rigid registration, and total BMD (TtBMD), bone volume fraction (BVTV), and void space volume faction (VSTV) were quantified at the first and last available timepoint for each participant. The cumulative formation of VSTV across sequential timepoints (termed void space expansion) was also quantified to capture structural voids that developed during fracture healing as opposed to those that arose due the fracture incident. Changes in BMD, BVTV, and VSTV between the first and last visit were compared using paired t-tests or Wilcoxon test, depending on data distribution.The median time of the first and last post-fracture visits were 1.1 weeks (IQR = 0.9-1.1) and 52.3 weeks (42.9-54.1), respectively. During this interval, VSTV increased five-fold in size from 1.0% (0.6-9.0%) to 5.5% (2.5-12.4%) (Figure 1A, p=0.01). Void space expansion occurred more rapidly in the first 26 weeks of fracture healing (Figure 1B) and did not necessarily occur in the immediate fracture region, but rather the surrounding area (Figure 1C). In contrast, TtBMD and BVTV did not significantly differ between the first and last study visits, where TtBMD was 283 +/- 55 mg HA/cm3 and 269 +/- 62 mg HA/cm3 (p=0.16) at the first and last visit, and BVTV was 42 +/- 2% and 41 +/- 2% (p=0.48) at the first and last visit, respectively.This study suggests that there may be adverse changes in bone microarchitecture during fracture healing, despite the potential preservation of overall TtBMD and BVTV in the fracture and surrounding region. The formation of void spaces may have long-term implications on patient bone strength and could provide insight into who is at risk of re-fracture.

Nanoscale Material Properties of Bone Tissue Near Lacunae in Type-1 Diabetics *Maxwyll McConnell[1], Wen Qian[1], Joseph Turner[1], Eleftherios Paschalis[2], Sue Bare[3], Laura Graeff-Armas[4], Joan Lappe[3], Robert Recker[3], Mohammed Akhter[5]. [1]University of Nebraska Lincoln, United States, [2]Ludwig Boltzmann Institute for Osteology, Austria, [3]Creighton University, United States, [4]University of Nebraska Medical Center , United States, [5]Creighton University Osteoporosis Research Center, United States

The risk of skeletal fracture in Type-1 diabetes (T1DM) is much higher than in non-diabetics; however, the data comparing bone tissue's material properties are scarce. We hypothesized that bone quality (structural and material properties) in T1DM patients is compromised. Bone mineral density (BMD) does not explain the elevated fracture-risk in T1DM, and thus, studies characterizing intrinsic material properties in bone tissue are needed. This study quantified the intrinsic material properties of bone tissue at the peri-lacunar space (Figure-1).Using quasi-static nanoindentation, we quantified local/intrinsic material properties of reduced modulus (GPa) and hardness (GPa) in lacunae-near and lacunae-far regions in trabecular bone of the iliac crest bone biopsies from postmenopausal women diagnosed with T1DM (N = 8, T1DM Cases; duration of disease > 10 years), and age- and BMD-matched postmenopausal women controls (N = 4, Control). The lacunae-near region is defined as within 5 micrometers of a lacunae, and the lacunae-far region is from 15-25 micrometers (Figure-2. Indentations were made with a Berkovich tip & target force of 6,000 µN (micronewtons) at a constant loading rate of 400 µN/s (micronewtons per second). For each lacuna, 4 near and 4 far indentations were completed, providing 8 hardness and reduced modulus values. An average of 3 lacunae were analyzed one for each bone sample, with a total of 12 samples analyzed.Results: In trabecular bone tissue near peri-lacunar space, no significant difference between lacunae-near and lacunae-far hardness or reduced modulus within each group (Case, Control) was observed. Thus, the data (near and far) were combined within each group (Case, Control) and analyzed. The combined lacunae (Table-1) show significant difference ($P < 0.05$) in hardness and modulus between the Cases and Controls, both higher in Control (Table-1) compared to Cases (T1DM).These preliminary findings of increased modulus and hardness (peri-lacunar space) in T1DM samples are different from what was previously found at cement lines in the same biopsies and suggest that the lacunar-based mineral accumulation (based on diffusion) mechanism is different than the one governing either interstitial or cement lines. Moreover, they suggest potential canalicular network density differences between Cases and Controls. Additional work is needed to verify the mechanisms governing, and the properties of the bone tissue in the peri-lacunar bone tissue.

Improving the rigor of fully convolutional neural networks trained to segment cortical from trabecular bone in high resolution computed tomography images *ERIN BIGELOW[1], Robert Goulet[2], Bonnie Brooker-Nolan[3], Kathryn Kennedy[4], Chandan Kadur[3], James Bird[3], Samantha Hertz[3], Emily Wittrup[3], Kayvan Najarian[3], Todd Bredbenner[5], Karl Jepsen[3]. [1]UNIVERSITY OF MICHIGAN, United States, [2]Michigan Medicine, University of Michigan, United States, [3]University of Michigan, United States, [4]Marquette University, United States, [5]University of Colorado Colorado Springs, United States

Segmenting cortical from trabecular bone is a critical step in the rigorous morphological analysis of computed tomography images. As manual segmentation is impractical for high resolution nano/micro-computed tomography volumes of human femoral necks, a fully convolutional neural network (FCNN) was created using Dragonfly software (Object Research Systems, Inc; Montreal, CA) to reduce personnel time and improve segmentation objectivity. The initial cortical boundary was defined based on work by others that considered mineralized tissue with low porosity as cortical bone. This decision resulted in a 'low porosity-preserving' FCNN, allowing the cortex to thin as resorption-based pores accumulated. This FCNN followed strict and consistent boundary protocols. Ground truth images were created by three trained researchers identifying cortical bone for each slice, and including any voxel selected by at least two researchers. This FCNN utilized 149 slices for training, 17 for validation, and 20 for testing from 20 femoral neck volumes; the patch size was 144 and batch size was 16. The DICE coefficient for this FCNN was 0.98. Despite the high DICE coefficient, we created a quality improvement process to systematically fix errantly segmented voxels. This process resulted in additional slices of ground-truth quality images, which were used to update the FCNN. The updated FCNN used 321 slices from 51 femoral neck volumes, split 70/20/10% for training, validation, and test sets with a patch size of 192 and batch size of 64. The slices were rotated in three directions and added so the network was trained with key features in different orientations. The DICE coefficient was 0.97.To confirm the updated FCNN could be used without substantive error corrections, a study was conducted using 11 femoral neck volumes, comparing morphological parameters following an in-depth quality check to a quality check that removed false positive voxels only. The outcomes showed strong correlations for BV/TV ($R2=0.9915$, $p<0.0001$), Ct.Ar. ($R2=0.9741$, $p<0.0001$), and Tt.Ar. ($R2=0.9959$, $p<0.0001$), confirming the FCNN with minimal error corrections estimated morphological parameters accurately. Thus, we show that a FCNN can be trained to accurately segment cortical from trabecular bone in high-resolution images, saving countless hours in labor and simultaneously improving rigor. The updated FCNN is available for public use.

Mechanical Loading & Withdrawal Relative to Menarche: An Exploratory Application of SITAR Grouping Functions to Radius Adaptations during Human Growth *Jodi Dowthwaite[1], Laure Spake[2], Tim Cole[3], Tamara Scerpella[4]. [1]SUNY Upstate Medical University; Binghamton University, United States, [2]Binghamton University, United States, [3]University College London, United Kingdom, [4]University of Wisconsin, United States

Purpose: Mechanical loading may be osteogenic during growth, but adaptations vary by hormonal milieu. Few human studies have tracked loading and withdrawal relative to menarche to assess estrogen-loading interactions. We evaluated an extreme model of mechanical loading using SITAR group functions to compare growth curves in ex-gymnasts (EX: quit pre-menarche) and gymnasts (GYM: quit post-menarche) vs. the non-gymnast standard (NON), centered by individual ages at menarche. Peak growth velocity (PkV) and magnitude (SIZE) patterns were hypothesized as: 1) NON= late/low PkV, low SIZE; 2) EX= early/high PkV, medium SIZE; 3) GYM= early/high PkV, high SIZE.Methods: From 1997-2023, annual DXA scans yielded 1/3 & ultradistal (UD) radius bone mass, projected area, and areal bone mineral density [BMC (g), AREA (cm2), BMD (g/cm2)]. Age was centered by individual ages at menarche, recentered by grand mean age at menarche (13.2y), and LN-transformed for menarche-centered modeling. For each outcome, we used SuperImposition, Translation And Rotation (SITAR package: R) to model & compare growth curve parameters for EX & GYM vs. the NON standard. Loading was assessed via significant EX & GYM group regression terms for SITAR parameters [SIZE, TIMING, INTENSITY; alpha <=0.05].Results: Longitudinal data for 124 girls were restricted to age 8-<21y in the three groups [NON=61, EX=16, GYM=47]. EX/GYM TIMING showed early PkV for all UD outcomes and 1/3BMC, plus GYM 1/3AREA ($p<=0.05$). For both sites, GYM INTENSITY was higher for AREA & BMC (trend high BMD: $p<=0.20$). In contrast, EX UDBMD INTENSITY was lower (trend low UDBMC & 1/3BMD: $p<=0.14$). GYM SIZE was highest across all outcomes, while EX retained UDBMD SIZE benefits ($p<=0.05$) (EX trend high 1/3AREA, 1/3BMD: $p<=0.17$).Conclusion: Hypotheses were broadly supported, with loading through menarche conferring GYM advantages in bone geometry, mass, and density as SIZE (all), TIMING (all but 1/3BMD), and INTENSITY (all but BMD, both sites). EX & NON patterns suggest pre-menarcheal loading spurs earlier TIMING of radius PkV, while NON TIMING relies on an estrogen boost circum-menarche. In EX, pre-menarcheal loading withdrawal blunted PkV INTENSITY and tempered SIZE benefits, but small sample and heterogeneous loading challenged clarity of EX pattern definition. Furthermore, data were modeled as raw DXA output; thus, radius SIZE comparisons do not account for individual height or weight differences (GYM-EX-NON).

Robotic Walking on Bone and Muscle Health in Children with Cerebral Palsy: A Case Study *Erin Hodgosn[1], Leigh Gabel[2], Elizabeth Condliffe[2]. [1]Univeristy of Calgary, Canada, [2]University of Calgary, Canada

Cerebral Palsy (CP) is the most prevalent childhood motor disability affecting ~2-3/1000 children. Weight-bearing physical activity is essential for developing a strong skeleton however, ~1/3 children with CP cannot walk independently, compromising bone health. As such, research into novel robotic trainers provides a promising opportunity for children with mobility impairments. Robotic gait trainers offer partial weight-bearing and independence while providing support and stability. Therefore, the aim of this study is to assess whether the Trexo robotic gait trainer provides sufficient loading to improve muscle and bone health in children with CP.Participants who are unable to walk in community settings are asked to train >=30 mins/day >=5 days/week walking in the Trexo. Bone and muscle health are measured through peripheral quantitative computed tomography (pQCT) prior to and following 3 months of training at the 3%, 38%, and 66% measurements of the participant's tibia. To differentiate between longitudinal growth and intervention effects, bone mineral density (BMD) and content (BMC) are expressed as age-specific z-scores based on normative pQCT data from a healthy population.To date, one 5-year-old male participant has completed baseline and follow-up scans. Trabecular BMD and total BMC at the 3% site were significantly lower compared with reference data in children without CP (-5.9 and -7.1 standard deviations below the mean, respectively). BMD increased by 9.3% (10.3 mg/cm3) at the 3% site with z-score improving to -5.4 at follow-up. BMC increased by 8.4% (4.1 mg/mm) over the trial period with an increase in z-score to -6.7 at follow up. We were unable to analyse the 38% and 66% slices due to significant motion artifact, which is a challenge studying this population. An improvement in BMD and BMC z-scores over 3-months at the distal tibia is encouraging; however, a greater sample size is needed to confirm if it is due to robotic gait training.Preliminary findings suggest the Trexo trainer may be a promising therapeutic device for improving bone health in populations with mobility challenges.

Relative growth rates for height among children and adolescents living with HIV on antiretroviral therapy *Tafadzwa Madanhire[1], Victoria Simms[1], Nyasha Dzavakwa[1], Cynthia Mukwasi-Kahari[1], Rashida Ferrand[1], Nuredin Mohammed[2], Amy MacDougall[2], Kate Ward[3], Celia Gregson[4]. [1]Biomedical Research and Training Institute, Zimbabwe. [2]London School f Hygiene and Tropical Medicine, United Kingdom. [3]MRC Lifecourse Epidemiology Centre, University of Southampton, United Kingdom. [4]University of Bristol, United Kingdom

Purpose: Perinatally acquired HIV is a treatable chronic condition such that through antiretroviral therapy (ART), children with HIV (CWH) are now surviving to adulthood. However, CWH often exhibit impaired growth. We aimed to identify the height growth patterns among CWH and determine age at peak height velocity (PHV).Methods: This is a secondary analysis of data collected prospectively in the ongoing VITALITY randomised controlled trial in Zimbabwe and Zambia. The trial has recruited 840 CWH (11-19 years) established on ART for at least 6 months, to determine whether vitamin-D3/calcium supplementation improves bone mass and strength with follow up to 96 weeks. Height is measured at 12 week intervals with currently (31 March 2023) 135 participants having completed 96 weeks of follow up. Weight and height for age were calculated using 1990 UK reference values, with Z-score<=-2 classifying those underweight and stunted. Analysis of height trajectories was performed using the Superimposition by translation and rotation (SITAR) adjusting for size, pubertal timing and growth rate and fitting the mean and velocity curves by sex.Results: We recruited 447(53.2%) females and 393(46.8%) males and followed them up for 1.37(IQR:1.15-1.1.61) years; at baseline median(IQR) age was 15(13-17) years and 30.0%(n=252) were stunted. CHW were taking ART for median(IQR) 9.8(6.3-12.3) years of their lives and 81.9%(n=688) were on an ART regimen containing tenofovir disoproxil fumarate. Lifetime fracture prevalence was 5.9%(n=50). At baseline (n=840), mean(SD) height for age was -1.70(1.06) and -1.22(1.05) for males and females respectively. Over 48 weeks (n=780), median(IQR) height gains were 3.3(1.1-5.9)cm and 1.2(0.3-3.5)cm for males and females separately. Age at PHV was 15.0 years (PHV:8.2cm/year) and 13.2 years (PHV:5.6cm/year) for males and females respectively.Conclusions: There is a high prevalence of stunting among CWH in Zimbabwe. Both males and females showed delayed PHV compared to regional estimates (females:11.8, males:14.4 years), raising concerns for persistent height deficits in adulthood known to impact human capital and function in later life.

Bone Density in Children with Avoidant/Restrictive Food Intake Disorder - Preliminary Results from an Ongoing Cross-Sectional Study *Eugene Rodrick[1], Kaitlin Proctor[2], Staci Belcher[1], Janasha Goffigan-Holmes[2], Wang Shin Lei[1], William Sharp[2], Joseph Kindler[1]. [1]Nutritional Sciences, University of Georgia, United States. [2]Emory University School of Medicine and Children's Healthcare of Atlanta, United States

Avoidant/restrictive food intake disorder (ARFID) was added to the DSM-5 to characterize patients with severe food avoidance/restriction in the absence of fear of weight gain or body dysmorphia. A robust body of evidence indicates that eating disorders, namely anorexia nervosa, are associated with severe bone deficits, but few studies have evaluated effects of ARFID on bone health. We are currently conducting a cross-sectional pilot/feasibility study in children with ARFID to characterize effects on bone outcomes. Here, we report preliminary results from 7 children (4 males) who have completed study visits. Total body (TB; less head), lumbar spine, hip, and 1/3 radius bone mineral density (BMD) and bone mineral content (BMC) were assessed via dual-energy X-ray absorptiometry (DXA). Z-scores were computed using published pediatric growth charts, which were then adjusted for height-for-age Z-score (HAZ). DXA Z-scores were compared to an expected mean of 0 using one-sample t-tests. The study sample was approximately 9.2+/-4.4 years of age and had an average BMI and height Z-score of 0.57+/-0.70 and -1.2+/-1.4, respectively. TB BMC (-0.97+/-0.74), TB BMD (-0.87+/-0.76), and femoral neck (FN) BMD (-1.18+/-0.69) Z-scores were significantly lower than 0 (all P<0.05; Figure 1). Based on a standard normal distribution, it would be expected that ~16% of children from a healthy population would have a Z-score <-1.0, but in this sample of children with ARFID, about 50% (n=3/6), 33% (n=2/6), and 60% (n=3/5) of subjects had a Z-score <-1.0 for TB BMC, TB BMD, and FN BMD, respectively. HAZ-adjusted bone Z-scores did not differ from 0. Pearson's correlations revealed significant positive associations between BMI Z-score and TB BMC (r=0.85), lumbar spine BMC (r=0.81), and HAZ-adjusted lumbar spine BMC (r=0.87) Z-scores (all P<0.05). In summary, these preliminary results indicate that shorter stature and associated bone deficits may be present in children with highly restricted food intake characteristic of ARFID. We aim to enroll an additional 13 children with ARFID to achieve our intended sample size for this ongoing study, which also includes the use of high-resolution peripheral quantitative computed tomography. Ultimately, results from this study will help inform larger prospective studies to more clearly define effects of ARFID on peak bone strength and inform clinical screening guidelines and interventions.

Total Calcium Intake is Associated with Trabecular Bone Density in Adolescent Girls with Type 1 Diabetes *Rylee Saunders[1], Kathleen Kilroe[1], Taisha Joseph[1], Signe Caksa[1], Mary Bouxsein[2], Madhusmita Misra[3], Deborah Mitchell[4]. [1]Endocrine Unit, Massachusetts General Hospital, United States. [2]Beth Israel Deaconess Medical Center, Harvard Medical School, United States. [3]Neuroendocrine Unit, Massachusetts General Hospital, United States. [4]Pediatric Endocrine Unit, Massachusetts General Hospital, United States

Aim: Type 1 diabetes (T1D) confers an increased risk of fracture, lower bone mineral density (BMD), and altered microarchitecture early in the course of disease. Adequate calcium (Ca) intake promotes bone mineralization, thereby increasing BMD. The goal of this analysis was to assess the associations of total daily Ca intake with bone outcomes and compare these associations between T1D and control youth.Methods: This was a cross-sectional analysis of girls ages 10-16 years with (n=62) and without (n=60) T1D. We measured Ca intake with a validated food frequency questionnaire. BMD, microarchitecture, and strength estimates were evaluated with dual energy x-ray absorptiometry and high-resolution peripheral quantitative computed tomography.Results: T1D and control participants had similar age and height, but BMI z-score was higher in T1D (p=0.003). Total daily Ca intake did not differ between groups (950 +/- 488 in T1D vs. 862 +/- 461 mg/day in controls, p=0.306). Serum 25OHD was lower in T1D (26.3 +/- 7.6 vs. 32.6 +/- 9.0 ng/mL, p=<0.001) and PTH was higher in T1D (38.9 +/- 11 vs. 33.4 +/- 9.7 pg/mL, p=0.004). Trabecular volumetric BMD and thickness at the tibia were lower in T1D (p=0.013, p=0.030). Ca intake correlated with trabecular BMD at the radius and tibia among T1D participants (?=0.27, p=0.047, and ?=0.28, p=0.027, ?=0.28 respectively) but not among controls (pinteraction=0.009 at the radius, pinteraction=0.010 at the tibia). Similarly, Ca intake was associated with estimated failure load at the tibia in T1D but not control participants (p=0.038, ?=0.18; pinteraction=0.051). We observed the expected negative association of Ca intake with parathyroid hormone in control (p=0.022, ?=-0.29), but not in T1D participants (pinteraction=0.022). Average glycemia as measured by hemoglobin A1c did not influence the relationship of Ca and PTH among participants with T1D (pinteraction=0.138). Fasting urinary Ca excretion was lower in T1D compared to control participants (p=0.043); we do not have measures of urinary Ca in the fed state.Conclusions: Patients with T1D may be particularly vulnerable to

dietary Ca insufficiency. We hypothesize that the lack of PTH suppression with increasing Ca intake is due to excess urinary losses in the fed state, driving a higher Ca requirement in T1D. Ca intake may be a modifiable risk factor for low BMD among youth with T1D. Ongoing studies will further clarify the role of Ca balance on bone density and accrual in youth with T1D.

Duchenne Muscular Dystrophy and Risk of Fracture *kelly Fuentes[1], Rubén Abdala[1], María José Columbres[2], Bellén Della Pía[2], Stefanía Rapelius[2], Patricia Rearte[2], Oscar Brunetto[2]. [1]Instituto de Diagnóstico e Investigaciones metabólicas , Argentina, [2]División Endocrinología, Hospital Pedro de Elizalde , Argentina

DMD is a rare genetic disease characterized by progressive muscular dystrophy . A high risk of fractures was reported in a patient with DMD which could be due to inmobilization, the pathophysiology of the disease , treatment with glucorticoids (GCs) and increased BMI . Knowledge of the risk factors for the disease contributes to creating preventive strategies that reduce co-morbidities and improve the quality of life in these patients.Objetive: To assess the incidence of first fractures and factors contributing to risk of first fracture in children with DMDMaterials and methodsA retrospective analysis of a cohort of patients with Duchenne Muscular was carried out A total of 27 children under 18 years of age with clinical and molecular diagnosis of DMD were enrolled. The study was approved by the ethics committee and all procedures were performed following the Declaration of Helsinki. The study began in 2010, a total of 27 children were referred to our endocrinology service for their evaluation. Anthropometric variables were evaluated at the start of the study and during follow-up. In addition, annual spine radiographs were performed. Data on long bone (LBF) and vertebral fractures (VF) were recorded. Questionnaires about calcium intake and mobility were also administered. The variables are summarized in mean (SD), median (IQR) and percentage according to their nature.Results: The age of DMD diagnosis was 6.52+/-2.83y and the follow-up time was 7.77 (+/-4.57y).Age of starting GCs was 8.12+/-2.45y and average daily was 0.6+/-0.12 mg/k/d. 7 children with new fractures (VF or LBF) were observed during this period, median time 5.07 (RIQ 3-6.66y) .Cumulative incidences was 0.26 or 26%. Children with fractures presented a delay in the age of diagnosis (8 vs 5.5 y) and increased BMI (p=0.01). No differences were observed in biochemical markers, vitamin D, time and dose of corticosteroids between fractured and non-fractured.Conclusion: We observed a high incidence of fractures in this population, which highlights the importance of a multidisciplinary approach and the creation of strategies to reduce modifiable risk factors to improve the quality of life of these children.

Prunes: The Bone Building, Barrier Enhancing, Gut Microbiota Altering Super Prebiotic *NICK CHARGO[2], Kavisha Patel[2], Leon Regnery[2], Narayanan Parameswaran[2], Robert Quinn[2], Laura McCabe[2]. [2]Michigan State University, , [2]Michigan State University, United States

Osteoporosis affects 50% of women in the US. Drug therapies are effective but haven't eliminated this silent disease. Women of all ages are searching for natural treatment options to improve bone health that are convenient, cost effective, and side effect free. Our lab and others have established the gut microbiota and intestinal barrier as key regulators of bone health. Promoting gut health with probiotics or intestinal barrier enhancers effectively prevents several etiologies of bone loss. Prebiotics/fiber increase beneficial gut bacteria and improve overall gut health. Prunes, a common natural fruit and prebiotic, have emerged as an effective way to prevent primary osteoporosis and alter gut microbiota composition, though mechanisms aren't fully understood.Can prunes further benefit the skeletal health of healthy adult female mice? We hypothesized that a prune diet would alter gut microbial composition, improve intestinal barrier function and increase bone volume. To test this, 16-week-old female C57BL/6J mice (n=10/group) were fed control or 25% prune (w/w) AIN-93M diets. At 5d, 10d, 4wks, 8wks, and 16wks sterile blood, bones, and colonic feces were collected. Remarkably, after only 5d on the prune diet, distal femur trabecular bone showed a significant 30% increase in BV/TV% assessed by micro-computed tomography (C: 16.62, P: 21.66, p=0.0026). Strikingly, bone volume continued to increase in the healthy female mice to >300% by 16wks (p<0.0001). Gut responses to the prune diet were also immediate. Colonic microbiota composition (16S rRNA gene sequencing) was significantly altered at early time points, based on PERMANOVA testing of beta-diversity matrices (Pseudo-F=19.647, p=0.001), and changes were maintained at later timepoints. Most importantly, intestinal barrier leakage, determined by serum endotoxin levels, was significantly reduced by 50% (p<0.0001) in the prune diet group after 5d and this benefit was maintained or further improved at later timepoints. The relationship between barrier leaks and low bone density was significant (r=-0.5598, p=0.0103), and the benefit of the prune diet on barrier function was associated with further increases in bone volume. We believe this to be the first study to show that prunes rapidly improve intestinal barrier function and correspondingly increase bone volume in healthy adult female mice. Analyses are currently underway to better understand the osteogenic mechanisms of this delicious snack!

Osteoarthritis-Associated Acceleration of Cognitive Dysfunction in a Mouse Model of Alzheimer's Disease *Wei Yao[1], Barton Wise[2], Ming Fan[2], Jill Silverman[2], Michael Pride[2], Yu-Yang Lin[2], Gabriela Loots[3], Blaine Christiansen[2]. [1]University of California, Davis Medical Center, United States, [2]University of California Davis Health, United States, [3]University of California, Davis, United States

Alzheimer's Disease (AD) and osteoarthritis (OA) are two of the most common health conditions affecting the elderly. Several recent studies have described an association between OA and AD, suggesting that prevalent OA increases the likelihood of AD. In this study, we investigated the association between OA and the onset of cognitive dysfunction in a mouse model of AD. APP/PS1 double transgenic mice express a chimeric mouse/human amyloid precursor protein (APP) and a mutant presenilin 1 (PS1), two mutations associated with early-onset cognitive decline and amyloid plaque formation. ?-Amyloid (A?) deposits in the brains of these mice are present by 7 months of age, while cognitive deficits are observable by 9 months. We hypothesized that OA-associated inflammation would be associated with worse early onset cognitive decline in APP/PS1 mice. We subjected 7-month-old male and female APP/PS1-Tg mice and wild type (WT) littermate controls to tibial compression-induced ACL rupture and evaluated their behavior and cognitive function 6 weeks post injury. Knees were assessed with microCT and whole-joint histology to quantify OA, osteophyte formation, and synovitis. A?, Tau, and pTau levels in the brain and knees were measured with ELISA and Western blot. Neurobehavioral tests included open field, novel object recognition, spontaneous alteration, and Morris water maze. We found that ACL injury induced similar OA severity in both WT and APP/PS1 mice, though female APP/PS1-OA mice had greater osteophyte formation than WT-OA mice. In APP/PS1-OA mice, A? in the brain was significantly greater than in the APP/PS1-Sham mice, and A? was increased in femoral subchondral bone and articular cartilage. Cognitive declines were primarily observed in female APP/PS1 mice. In the open field test, female APP/PS1 mice exhibited decreased exploratory behavior compared to WT mice, but no significant differences were observed between OA and Sham mice. For the novel object recognition test, female APP/PS1-OA mice did not have a significant preference for the novel object as would be expected. Significant differences between WT and APP/PS1 mice were also observed during the acquisition phase and the testing phase of the Morris Water Maze test, though no significant differences were observed between Sham and OA mice. These results provide insights about the pathoetiology of both AD and OA and suggest possible common mechanisms connecting OA-associated inflammation to cognitive function.

Fibroblast Growth Factor 23 and Physiological Responses to Phosphorus Intake in Pigs *Mariola Grez-Capdeville[1], Brittney P. Kokinos[1], Laura A. Amundson[1], Thomas D. Crenshaw[1]. [1]University of Wisconsin-Madison, United States

Fibroblast growth factor 23 (FGF23), is a bone-derived, protein hormone involved in the regulation of P homeostasis and vitamin D metabolism. FGF23 binds renal FGFR1c/?Klotho receptor complex to induce urinary P excretion and regulate the synthesis of active vitamin D. Biological roles of FGF23 were initially established in studies of humans with disorders of P metabolism and murine models. Pigs offer a large animal model for translational research on bone and mineral metabolism. This study aimed to validate the physiological roles of FGF23 on P metabolism in pigs. Dietary P was altered to assess the time course for synthesis and secretion of FGF23. Growing pigs (n=32) were fed a low P diet (LP, 0.34% P) for 4 days, fasted overnight, and then fed an excessive P diet (HP, 2.50% P) for 5 days. Blood and urine samples were collected throughout the experiment to determine concentrations of P. Pigs were euthanized (n=8/time) at day 4 of LP intake for assessments of baseline (0hr), and at 12, 36, and 108hr after consuming HP. Femur and kidney tissues were collected for assessment of P metabolism based on genes (RT-qPCR) and proteins (Western blot) of interest. Plasma P rapidly increased from approximately 5 to 18 mg/dl within 12hr of consuming HP followed by an increase in urinary P excretion. At maximal urinary P excretion (108hr), plasma P concentrations had recovered to normal physiological concentrations. Sodium-phosphate cotransporter (SLC34A1) protein decreased in pigs fed HP, confirming renal adaptations to P intake. Bone FGF23 mRNA expression was upregulated 20-fold after 12hr of HP relative to LP and reached a 150-fold increase by 108hr. The renal mRNA expression of FGFR1c increased slightly (1.5-fold) at 36hr of consuming HP. The ?Klotho mRNA was not affected by dietary P concentration. However, ?Klotho protein increased in response to HP. Changes in dietary P concentrations affected renal mRNA expression of vitamin D metabolizing enzymes by downregulating 1?-hydroxylase (CYP27B1) and upregulating 24-hydroxylase (CYP24A1) at 108hr. However, in bone, expression of CYP27B1 was not affected and CYP24A1 mRNA was downregulated in HP pigs. We conclude that dietary P induced FGF23 synthesis and that observed responses in pigs are consistent with phosphaturic effects of FGF23 in kidneys to maintain P homeostasis previously described for human and mice. Analyses to measure circulating concentrations of FGF23, PTH, and vitamin D metabolites are in progress.

Membrane Estrogen Receptor-? Signaling in POMC Neurons is Crucial for Normal Bone Metabolism in Female Mice *Yiwen Jiang[1], Karin Horkeby[1], Jianyao Wu[1], Karin Nilsson[2], PETRA HENNING[3], Sofia Movérare-Skrtic[4], Claes Ohlsson[5], Marie Lagerquist[4]. [1]Sahlgrenska Osteoporosis Centre, Centre for Bone and Arthritis Research at Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Sweden, Sweden. [2], Sweden. [3]UNIVERSITY OF GOTHENBURG, Sweden. [4]Medicine, Sweden. [5]Center for Bone and Arthritis Research at the Sahlgrenska Academy, Sweden

Estrogen receptor-? (ER?) signaling in the central nervous system is involved in the regulation of bone metabolism1,2. We have previously shown that deletion of ER?, specifically in proopiomelanocortin (POMC) neurons, increases bone mass and mechanical strength3. We and others have also revealed that membrane-initiated estrogen receptor-? (mER?) signaling plays an important role in regulating estrogenic effects in bone. However, it remains unknown whether mER? signaling in POMC neurons is involved in mediating estrogenic effects in bone.For this purpose, we have generated a novel ER?-C451Aflox/flox mouse model (C451Af/f) in which the C451A mutation disables the membrane localization of ER?. C451Af/f mice were mated with POMC-Cre mice to breed POMC-C451A mice, lacking mER? signaling in POMC-expressing neurons, and homozygous C451Af/f littermate controls.Phenotyping at 16 weeks of age showed multiple changes between POMC-C451A mice (n=8) and C451Af/f littermate controls (n=9). Areal bone mineral density (BMD), measured by DEXA, was significantly increased in POMC-C451A mice (total body, +5%, p<0.001; lumbar spine, +16%, p<0.001). Cortical thickness and trabecular BMD, measured by pQCT, were increased in long bones (cortical thickness: femur, +13%, p<0.001, tibia, +13%, p<0.001; trabecular BMD: femur, +32%, p<0.05, tibia, +29%, p<0.001). In addition, cortical bone in vertebrae L5 and bone volume fraction (BV/TV), measured by ?CT, were also increased in POMC-C451A mice compared with controls (BV/TV: +37%, p<0.001; cortical thickness: +18%, p<0.01). Uterus weight was unaffected in POMC-C451A mice, suggesting normal sex steroid feedback regulation.In conclusion, our study emphasizes the inhibitory effect of neuronal ER? signaling on bone mass, in contrast to the stimulatory bone effects by peripheral ER? signaling. This demonstrates that mER? signaling in POMC neurons plays an important role in this negative regulation of bone mass.Reference1. Herber CB, et al. Nat Commun, 2019.2. Ohlsson C, et al. Differential substrate utilization in isolated mitochondria from skeletal muscle of BNIP3 null mice *Rea Victoria P. Anunciado-Koza[1], Victoria Van Berlo[1], Li Tian[1], Calvin Vary[1], Carlos Gartner[1], Robert Koza[1], Anyonya Guntur[2]. [1]CMM, United States. [2]MaineHealth Institute for Research , United States

BNIP3 (Bcl2/adenovirus E1B 19 kDa like interacting protein3), a mitophagy receptor, is an important regulator of cellular function in response to stress. In muscle cells and myotubes, BNIP3 regulates mitophagy and is necessary for maintaining mitochondrial health. To characterize the role of this protein in regulating mitochondrial bioenergetics in the skeletal muscle, we isolated mitochondria from quadriceps femoris of male and female wildtype and Bnip3 KO mice. Next, we utilized a novel Percoll gradient mitochondrial isolation process that yields purified, ATP generation coupled mitochondria, which could be evaluated with the Agilent Seahorse XFe96 analyzer, and subsequently by SWATH liquid chromatography mass spectrometry, to determine mitochondrial respiration and mitochondrial protein expression, respectively. Mitochondrial coupling and electron flow assays using the XFe96 analyzer showed mitochondria derived from BNIP3 null muscle had similar responses to various substrate combinations, except for palmitate, where the mitochondria isolated from male BNIP3-null mice displayed a decrease in oxygen consumption rate. Furthermore, BNIP3 null mitochondria from both male and female mice showed higher activity of electron transport chain Complexes I, II and IV. SWATH proteomics identified a mitochondrial protein expression signature (~450 mitochondrial associated proteins quantified) that were significantly different in the absence of BNIP3 (fold change, Welch's t-Test; P<0.05). We validated selected proteins via western blotting. These data suggest dysregulation of mitochondrial metabolism as a potential mechanistic explanation for some of the metabolic phenotypes seen in the absence of BNIP3 in mice.

Deletion of Fra1 in osteoblasts by Runx2-Cre causes a reduced adipose tissue mass *Julia Luther[1], Mona Neven[1], Olga Winter[1], Lana Rosenthal[1], Michael Amling[1], Jean-Pierre David[1], Thorsten Schinke[1]. [1]Institute for Osteology and Biomechanics (IOBM), University Medical Center Hamburg-Eppendorf, Hamburg, Germany, Germany

The activator protein-1 (AP-1) transcription factor family member Fra1 has been described to cause increased bone mass and decreased adipose tissue mass when ubiquitously overexpressed in mice. Epiblast-specific deletion of Fra1 by More-Cre, conversely, caused

osteopenia due to a decreased bone formation rate. In vitro experiments with primary calvarial osteoblasts showed a reduced mineralizing activity. Osteoclast number and activity was not affected in vivo, however, osteoclasts showed a differentiation defect in vitro.To analyse the cell autonomous phenotype in vivo, we generated mice with an osteoclast- or an osteoblast-specific deletion of Fra1 (Fosl1) using LysM-Cre and Runx2-Cre, respectively. Deletion of Fra1 specifically in osteoclasts did not lead to a change in trabecular bone mass in 12-week- or in 1-year-old LysM-Cre;Fra1fl/fl mice compared to control animals (14.23+/-3.49% (control) versus 12.85+/-2.733% (LysM-Cre;Fra1fl/fl) at the age of 1 year). In addition, osteoclast number per bone perimeter was not affected in young mice (N.Oc/B.Pm: 4,307+/-1,86mm-1 (control) versus 4,928+/-1,42mm-1 (LysM-Cre;Fra1fl/fl)), confirming that Fra1 is not necessary for osteoclast differentiation in vivo. When deleting Fra1 in osteoblasts no significant change in bone mass was observed in 12-week as well as 1-year-old Runx2-Cre;Fra1fl/fl compared to control mice (15.53+/-2.243% (control) versus 13.36+/-0.7766% (Runx2-Cre;Fra1fl/fl) at the age of 1 year). Furthermore, the number of osteoblasts was unchanged in 12-week-old mice (N.Ob/B.Pm: 32,24+/-6,54mm-1 (control) versus 39,38+/-9,66mm-1 (Runx2-Cre;Fra1fl/fl)). However, we could observe a significantly reduced adipose tissue mass accrual in mice with an osteoblast-specific deletion of Fra1, accompanied by a lack of increase in adipocyte cell diameter in 1-year-old Runx2-Cre;Fra1fl/fl mice. Thus, Fra1 expression in Runx2-Cre positive pre-osteoblasts regulates adipose tissue metabolism. In contrast, the bone-anabolic function might be driven by Fra1 expression in early mesenchymal osteoblast progenitors rather than in committed pre-osteoblasts.

Evidence of age-relate bone alterations in a mouse model of Alzheimer's disease *Surendra Kumar[1,] Mei Wan[1,] Ching-Lien Fang[1,] Jiekang Wang[1,] Xu Cao[2,] Janet Crane[2,] Shadpour Demehri[3,] Richard Skolasky[3,] [1]Department of Orthopedic Surgery, Center for Musculoskeletal Research, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205, USA., United States, [2]Johns Hopkins University, United States, [3]Center for Musculoskeletal Research, United States

Osteoporosis and dementia, two common degenerative diseases in the elderly population, often occur simultaneously. Reduced bone mineral density and osteoporosis occur at a much greater rate in patients with Alzheimer's disease (AD), often emerging in the disease before the appearance of significant cognitive decline. Although it is known that the brain regulates bone homeostasis and regeneration, there is limited research investigating bone alterations and how the changes in relation to brain degeneration in mouse models of AD. In this study, we conducted a systemic characterization on the bone phenotype in parallel of brain changes in APPswe/PS1dE9 (APP-PS1) transgenic mice, a well-established mouse model of AD Alzheimer's disease. We found that 9-month-old APP-PS1 mice developed brain degeneration, neuroinflammation, and cognitive impairment, as evidenced by accumulated A? plaque, increased numbers of activated microglia and astrocytes, neuron loss, and declined cognitive functions. Micro-CT analysis of tibial bone samples from 9 month-old APP-PS1 mice and age-matched wild-type littermates (WT) revealed a low-bone-mass phenotype in APP-PS1 mice, characterized by significantly lower bone volume/tissue volume (BV/TV), trabecular thickness (Tb.Th), trabecular number trabecular number (Tb. N), and an increase in trabecular separation (Tb.Sp) relative to wild-type littermates (WT). Cortical bone volume and cortical thickness of tibia were not significantly different in APP-PS1 mice compared to WT mice. Histomorphometry analysis showed a lower osteoblast cell numbers per bone surface (N. Ob/BS) and an increase in osteoclast number per bone surface (N. Oc/BS) in APP-PS1 mice compared to the control group. Moreover, we found a markedly increased bone-marrow adipose tissue in APP-PS1 mice vs. WT mice, as evidenced by higher adipose tissue volume per total volume (%AV/TV) detected by ?CT scan of the osmium tetroxide-stained bone tissue. Consistently, there is increased perilipin+ adipocytes in the bone marrow of APP-PS1 mice vs. WT mice as detected by immunofluorescence staining of tibia bone tissue sections. Together, these findings demonstrate that AD mice have significant bone microarchitectural and cellular changes, which recapitulate age-related bone phenotype. The finding also illuminates a need to define a mechanistic relationship between bone loss and brain deficits in early AD.

TERT and STAT5 initiate the osteogenic differentiation of cells in calcific aortic valve disease *Cynthia St. Hilaire[1,] [1]University of Pittsburgh, United States

Calcific aortic valve disease (CAVD) is the pathological remodeling of the aortic valve leaflets which leads to heart failure and high stroke risk. While several mechanisms are known to drive cardiovascular calcification, the initial steps orchestrating the osteogenic reprogramming of cells are not fully understood. Previous studies have shown that over expression of telomerase reverse transcriptase (TERT) primes mesenchymal stem cells to differentiate into osteoblasts. While TERT is best known as the enzymatic cofactor to the telomerase complex that caps telomeres at the end of chromosomes, non-canonical transcriptionally regulatory functions of TERT have been identified. We investigated whether TERT contributes to osteogenic reprogramming of valve interstitial cells. Immunofluorescent imaging revealed that TERT protein was highly expressed in calcified valve leaflets. These phenotypic features were retained in primary valve interstitial cells (VICs) isolated and cultured from diseased tissues. In vitro disease modeling found that TERT levels were increased with osteogenic or inflammatory stimuli, and genetic deletion or reduction of TERT prevented calcification of VICs. Similar results were seen in coronary artery smooth muscle cells (CASMCs) and mesenchymal stem cells (MSCs). In silico analysis of the Runt-Related Transcription Factor 2 (RUNX2) gene promoter identified several putative binding sites for the transcription factor STAT5. Immunofluorescent staining, immunoprecipitation, and proximity ligation assays show that TERT and STAT5 protein colocalize in cells under osteogenic treatment. STAT5 binding to the RUNX2 gene promoter was confirmed with chromatin immunoprecipitation and Cut&Run sequencing. TERT and STAT5 were also found to co-localized in calcified valve tissues. Genetic depletion of TERT or STAT5, as well as pharmacological inhibitors specific for STAT5 prevented calcification of VICs, CASMCs, and MSCs in vitro. Cells from Tert+/+ and Tert-/- mice were used to validate human findings. Together, these data show that TERT in conjunction with STAT5 initiate the osteogenic transition of cardiovascular cells and identify a novel therapeutic target to abate vascular calcification.

Dose Response Effects of Leptin on Polyethylene Particle-Induced Calvarial Osteolysis and Systemic Bone Loss in Leptin-Deficient ob/ob Mice *Russell T. Turner[1,] Kenneth Philbrick[1,] Adam Branscum[1,] Urszula Iwaniec[1,] [1]Oregon State University, United States

Particles generated from wear of prosthesis joint-bearing surfaces (often polyethylene) induce inflammation-mediated periprosthetic bone resorption (osteolysis), a risk factor for implant failure. Additionally, circulating wear particles may induce systemic bone loss. While obesity is a risk factor for implant failure, morbidly obese leptin-deficient ob/ob mice are resistant to osteolysis induced by polyethylene particles placed over their calvaria. Leptin increased osteolysis in ob/ob mice suggesting that the adipokine, an important immune modulator produced by adipocytes in proportion to fat stores, may contribute to implant failure. To investigate this possibility, we performed two dose response studies. In the first study, we administered leptin via s.c. implanted osmotic pumps to 6-week-old female ob/ob mice for 2 weeks at 12, 120 or 400 ng/hr (n=8/group). Compared to untreated ob/ob mice (n=8), changes in cancellous bone volume/tissue volume (BV/TV) were not observed for distal femur metaphysis or 5th lumbar vertebra (LV5). Compared to wild type (WT) mice (n=8), serum leptin was normal in ob/ob mice treated with 120 ng/hr leptin and ~2-fold higher in mice treated with 400 ng/hr. In the second study, polyethylene particles were implanted over calvaria of ob/ob mice. The treatment groups (n=7-10/group) consisted of no treatment, particles, and particles + leptin (12, 120 or 400 ng/hr). Osteolytic bone pitting was not observed in control mice but was present in particle-treated mice. Compared to particle-treated mice, bone pitting was higher in calvaria of mice administered leptin at 120 ng/hr but no further increase was observed at 400 ng/hr. BV/TV was higher in distal femur metaphysis and LV5 in untreated mice when compared to particle-treated mice. In contrast, BV/TV was lower in distal femur metaphysis and LV5 in mice infused with 400 ng/hr leptin but unchanged at lower dose rates. In summary, leptin had no effect on BV/TV in ob/ob mice evaluated 2 weeks following initiation of leptin treatment. Calvarial osteolysis and systemic bone loss were observed in ob/ob mice following particle challenge. Increasing serum leptin to WT levels resulted in an increase in calvarial osteolysis and hyperleptinemia resulted in an increase in systemic bone loss. Taken together, these findings suggest that leptin, while not required for polyethylene particle-induced osteolysis and systemic bone loss, may contribute to implant failure in obese subjects.

IL-34 mediated osteolysis exacerbates pathogenic features of Alzheimer's disease *Anny Ho[4,] CHIAKI YAMADA[2,] Bidii Ngala[3,] Amilia Nusbaum[3,] Carolina Duarte[4,] Juliet Akkaoui[5,] Christopher Michael Garcia[6,] William Kochen[4,] Alexandru Movila[3,] [4]Nova Southeastern University, United States, [2], , [3]Indiana University School of Dentistry, United States, [4]Nova Southeastern University, , [5]Florida International University, United States, [6]Indiana University School of Medicine, United States

Alzheimer's disease (AD) is characterized by progressive neurodegeneration and a gradual decline in memory and cognitive functions. The hallmark features of AD are associated with elevated accumulation of aggravated amyloid beta (A?) peptides, hyperphosphorylated Tau (p-Tau), and neuroinflammation. Emerging evidence indicated that inflammatory osteolysis exacerbates AD neurodegeneration and neuroinflammation via unknown molecular mechanisms. Signaling through the colony-stimulating factor-1 receptor (CSF-1r) is critical for maintaining the physiological and pathological signaling of blood myeloid cells and microglia. CSF-1r is activated by macrophage colony-stimulating factor-1 (M-CSF) and interleukin-34 (IL-34). While the impact of M-CSF in bone physiology and pathology is well addressed, it remains controversial whether IL-34-mediated bone osteolysis promotes AD neuroinflammation and neurodegeneration. Surprisingly, we observed that IL-34 plays a critical role in inflammatory osteolysis in wild-type mice. To evaluate the effects of IL-34 on AD cognitive behavioral phenotype and neuroinflammation, female and male triple transgenic 3x-Tg AD mice and corresponding control were randomly divided into two experimental groups (10 mice/sex/group). Mice were subcutaneously injected with 100 µl of

mouse recombinant IL-34 protein solution in PBS or PBS alone over the calvaria bone every other day for 42 days. In addition, we compared the effects of IL-34 and M-CSF on macrophages, microglia, and RANKL-mediated osteoclastogensis in relation to AD pathology. This study demonstrated that local calvaria injection of recombinant IL-34 protein dramatically elevated AD-like memory loss, pathogenic amyloidogenesis, p-Tau, and neuroinflammation-associated RAGE expression in female 3x-Tg mice. Furthermore, IL-34 promoted calvaria inflammatory osteolysis compared to the sham control injected group of female and male mice. Our data also indicated that IL-34-microglia and bone-marrow-derived macrophages isolated from 3x-Tg mice released significantly higher amounts of pro-inflammatory cytokines, TNF-?, IL-1?, and IL-6, compared to M-CSF-proliferated cells in vitro. In addition, IL-34 elevates RANKL-primed osteoclastogenesis in the presence of key AD-associated A?40 and A?42 peptides. Therefore, our data indicated that a novel therapeutic regimen targeting IL-34 could suppress neuroinflammation, neurodegeneration, and elevated bone loss observed in patients with AD.

Angiotensin-(1-7) attenuated LPS-induced osteoclastogenesis and bone resorption via inhibiting the activation of MAPK pathway in macrophages
*Jiayi Ren[1], Hideki Kitaura[1], Takahiro Noguchi[1], Fumitoshi Ohori[1], Aseel Marahleh[3], Jinghan Ma[1], Kayoko Kanou[1], Mariko Miura[1], Kohei Narita[1], Itaru Mizoguchi[1], Aseel Marahleh[0]. [1]Division of Orthodontics and Dentofacial Orthopedics, Tohoku University Graduate School of Dentistry, Japan. [3]Tohoku University, Japan. [0]Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, Japan

Renin-angiotensin-aldosterone system plays a crucial role in regulation of blood pressure and fluid homeostasis. It is reported to be involved in mediating bone-related inflammatory diseases such as osteoporosis. Angiotensin-(1-7), as a well-studied component of RAS recently, is a product of Angiotensin I and II (Ang I, II) cleaved by Angiotensin-converting enzyme 2 (ACE2), binds to Mas receptor (MasR) to counteract inflammatory effects produced by Ang II. However, it remains unclear whether Ang-(1-7) reduces bone resorption by inhibiting osteoclastogenesis. Therefore, the objective is to elucidate the effects of Ang-(1-7) on inflammation-induced osteoclastogenesis. In vivo, mice were supracalvarial injected with Ang-(1-7) or LPS +/- Ang-(1-7) subcutaneously. Micro-CT, tartrate-resistant acid phosphatase (TRAP)-stain and real-time PCR were applied to compare bone resorption and osteoclast formation. In-vitro, RANKL/TNF-? +/- Ang-(1-7) were added to cultures of bone marrow-derived macrophages (BMDM) and osteoclast formation was measured via TRAP staining. The effects of Ang-(1-7) on LPS-induced osteoblasts RANKL expression and peritoneal macrophages TNF-?, IL-6 expression were also investigated. Signaling fluctuation in mitogen-activated protein kinase (MAPK) pathway was studied using Western blot. Consequently, in vivo, Ang-(1-7) attenuated TNF-?, TRAP and Cathepsin K expression from calvaria, and decreased osteoclast number along with bone resorption at the suture mesenchyme. In vitro, Ang-(1-7) tended to reduce LPS-stimulated macrophages TNF-? and IL-6 expression. Additionally, Ang-(1-7) did not inhibit osteoclastogenesis induced by RANKL/TNF-? nor reduce osteoblasts RANKL expression. Ang-(1-7) attenuated the phosphorylation of P38, ERK1/2 in MAPK pathway in LPS activated macrophages. The results suggested a further study in cell-cluster of which affected by Ang-(1-7) during inflammation related bone diseases.

Impact of sex hormone deficiency in mice expressing the Alzheimer´s disease-associated risk-factor TREM2 R47H variant in a sex and genotype dependent manner
*JULIAN BALANTA-MELO[1], Padmini Deosthale[2], Rachel Kohler[3], ALYSON ESSEX[4], Chiebuka Okpara[5], Matthew Arnett[2], Madison Gerbig[2], Joseph Wallace[6], Lilian Plotkin[2]. [1]Universidad del Valle, Colombia. [2]Indiana University School of Medicine, United States. [3]Biomedical Engineering, IUPUI, United States. [4]Indiana University , . [5]Lehigh University, United States. [6]Indiana University Purdue University Indianapolis (IUPUI), United States

Expression of the R47H variant of the Triggering Receptor Expressed on Myeloid Cells 2 (TREM2), a risk factor for Alzheimer´s disease in humans and leads to lower bone mass and strength in female but not male 13-month (mo) mice, compared to wild type (WT) littermates. To assess if, as with aging, gonadectomy (GNX) leads to sex-specific musculoskeletal effects, gonad removal or SHAM surgery were performed in 4mo TREM2R47H/+ mice and WT littermates (N=10-12/group). Body weight (BW), BMD and body composition (DXA) were assessed at baseline (0), 3 and 6 weeks (w) post-surgery, and plasma P1NP and CTX at 3 and 6w. After euthanasia at 6w, hindlimb muscles were weighted and femora were tested by µCT, histomorphometry and 3-point bending test. Sexes were analyzed separately by 2-Way ANOVA followed by post hoc multiple comparisons (see Table). At 6w, GNX led to lower BW in males, higher lean mass in females, and higher fat mass in both sexes, independent of the genotype. Also, GNX reduced spine/femur BMD in SHAM R47H males at 3w and total/spine/femur BMD at 6w for all sex/genotypes, compared to baseline. When compared to SHAM mice, GNX led to lower Quadriceps weight in WT males and Quadriceps and Tibialis anterior (TA) in R47H males, whereas it did not change muscle weight in WT females but led to higher TA and Gastrocnemius weight in R47H female mice. Microstructural analysis of femur showed that GNX resulted in lower BA/TA (cortical mid-diaphysis) and Tb.Th (distal) in WT and R47H males, respectively. Moreover, sex hormone deficiency led to lower Ct.Th, BV/TV and Tb.N, and higher Tb.Sp, in WT/R47H males and WT females, but not R47H females. Interestingly, GNX resulted in higher marrow cavity area only in R47H females. Bone formation parameters from femoral mid-diaphysis showed that WT/R47H males and WT females that underwent GNX exhibited lower periosteal MAR and BFR/BS, with no changes in endocortical bone formation or osteoclast-related parameters. At 6w compared to 3w, circulating resorption/formation markers were higher in SHAM/GNX WT males (CTX-I) and SHAM WT females (P1NP) and lower (CTX-I, P1NP) in GNX WT females. GNX also led to sex-dimorphic effects on femur biomechanical properties, with worsening effects in R47H mice and improved parameters in mutant females (Table 1). Thus, R47H TREM2 variant expression is a risk factor that worsens sex hormone deficiency impact in the musculoskeletal system in males, whereas it has a protective role in female mice.

Difference between TBS and HR-pQCT in a group of patients with acromegaly
*Mariana Soledad Gonzalez Pernas[1], Fernando Jerkovich[1], Gloria Tubert[2], Debora Katz[3], Dolores Clifton Goldney[1], Patricia Slavinsky[3], Karina Danilowicz[4], Vanesa Longobardi[1], Mariela Sesta[1], Maria Belen Zanchetta[1]. [1]IDIM, Argentina. [2]Hospital Gral de Agudos “Dr. Fernandez”, Argentina. [3]FLENI, Argentina. [4]Hospital de Clinica ‘Jose de San Martin”, Argentina

Introduction: Clinical guidelines suggest performing spinal RX and DXA in acromegalic patients due to the high prevalence of vertebral fractures (VFx) in this population. Trabecular and cortical bone microarchitecture deterioration could better explain the occurrence of these fractures. A prospective study was designed to describe bone and muscular quality in a group of patients with acromegaly. The aim of this cross-sectional analysis was described baseline characteristics of the first female patients included.Methods: Clinical features, BMD and TBS measured by DXA (spine and hip), bone microarchitecture by HR-pQCT) and spine RX or VFA were assessed. The results of HR-pQCT were compared with a control population. A normal IGF-1 value without treatment was defined as remission, controlled disease with normal IGF-1 value under treatment and active disease with elevated values of IGF-1.Results: The first 22 women were included for this analysis; median age was 57 (23-84) yo. Only 4 patients were pre-menopausal. Regarding acromegaly status, 5 were in remission, 13 with controlled disease and 4 actives. None of the patients reported a history of vertebral fracture, 4 VFx were diagnosed in 2 patients. Mean DXA values were within the normal range as follow: LS 1.230+/-0.197g/cm2, TS 0.3+/-1.6, ZS 1+/-1.8; FN 0.942+/-0.157g/cm2, TS -0.7+/-1.2, ZS 0.4+/-1.2. One patient had osteoporosis and 5 patients with osteopenia. Mean TBS value was 1.398+/-0.113 within the normal range. Only 4 patients reported values below the normal range, but very close to the limit of normality (0.8 ULN). Significant trabecular parameters deterioration was found in most patients: total BMD was higher than expected, at the expense of increased cortical density that masks the decrease in trabecular volume and bone density, mainly due to a decrease in trabecular thickness (Table 1). The patients with VFx showed normal TBS values (1.365; 1.491) and abnormal values of trabecular parameters (Radius Tb.BMD: 79, 111; Tb.BV/TV: 6.6, 9.3 - Tibia Tb.BMD: 99,89; Tb.BV/TV: 8.3, 7.4) in HR-pQCT analysis.Conclusions: In this preliminary report, although BMD and TBS values by DXA were within the normal range, trabecular bone microarchitecture was much more severe than expected. A significant trabecular bone compromise with indemnity of cortical compartment was found both in radius and tibia. Specifically

in patients with VFx, TBS measured by DXA did not identify trabecular involvement and was evidenced by HR-pQCT.

SUN-072

Effects of antiemetic dexamethasone therapy on bone health in cancer patients receiving systemic chemotherapy *A Ram Hong[1.] [1]Chonnam National University Medical School, Republic of Korea

Objective: Chemotherapy-related nausea and vomiting is a critical issue in cancer patients. Dexamethasone plays an important role in mitigating chemotherapy-induced emesis because of its proven benefit in clinical trials, widespread availability in oral form, and low cost. Here, we aimed to investigate the effect of dexamethasone therapy as an antiemetic agent on bone health in patients with solid cancer undergoing systemic chemotherapy. Methods: This study included postmenopausal women and men aged 70 years or older with solid cancer who had been receiving systemic chemotherapy for at least 6 months at Chonnam National University Hwasun Hospital, which included dexamethasone at a dose of 8 mg or more every cycle as an antiemetic agent. Patients receiving anti-osteoporosis treatments, newly diagnosed osteoporosis at baseline, and a history of corticosteroid use within 6 months were excluded. Bone mineral density (BMD) of the lumbar spine (L1-4), femoral neck, and total hip was measured using dual-energy X-ray absorptiometry at baseline and 6 months after chemotherapy. Results: A total of 106 patients from May 2022 through Mar 2023 were included in the analysis. The mean age of the patients was 69.6 +/- 9.5 years, and men comprised 63.2% of the patient population. At baseline, 42.5% had normal BMD and 57.5% had osteopenia according to WHO criteria. Only 1 patient had a history of fragility fracture, and none of them had radiological vertebral fracture at baseline. Twenty-seven of 106 patients were included in the 6-month longitudinal analysis. Of those, 40.7% received calcium and vitamin D supplements during chemotherapy. The mean total dose of dexamethasone was 93.6 +/- 21.1 mg. At 6 months, femoral neck and total hip BMD significantly decreased from baseline with least significant mean changes of -0.026 and -0.044, respectively (P=0.002 and P=0.014, respectively). Lumbar spine BMD did not differ between baseline and 6 months after chemotherapy (least significant mean change of -0.017, P=0.069). Conclusion: Antiemetic dexamethasone therapy, indicative of cyclic glucocorticoid administration, resulted in significant bone loss during 6 months of chemotherapy in patients with solid cancers, especially in regions rich in cortical bone.

High-Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) as a new Method for Human Osteoarcheology *Peter Herbert Kann[1.] Tanja Pommerening[1.] Rainer Brömer[1.] Christopher John[1.] Peyman Hadji[1.] [1]Evolutionary Osteology Working Group, Philipp's University Marburg, Germany, Germany

In (pre)historic human bones, analysis of bone density and microstructure may be useful for anthropological research to assess skeletal health as well as physical fitness and handedness. Physical strain between arms and legs can be compared. HR-pQCT may provide information on such parameters, but has not been used in (pre)historic bones without soft tissue and bone marrow yet.Three macroscopically intact skeletons of young persons who died 100-125 years ago at an age of approximately 20 years could be identified in the medical-historical-anatomical collection in Marburg/Germany. Distal radii and titiae were measured using HR-pQCCT (XtremeCT, Scanco Medical) and analyzed with the standard evaluation script (software) used for patients in clinical routine. We analyzed (1) the quality of the pseudo-3D images of the bones in comparison to two healthy living persons of the same age group and (2) proved for which quantitative parameters plausible results could be calculated. [Ethical votum: EK_MR_17_03_23_kann].(1) The quality of the pseudo-3D images was completely comparable between the historical bones and those of young living persons. (2) Calculation of trabecular number, cortical thickness and cortical bone density revealed plausible results comparable to young living persons (77.5 + 26.9 % vs. 84.4 + 28.3 % of sex-related mean for persons 20 - 29 years old; n.s. [pooled data]). Calculation of trabecular bone volume / tissue volume and trabecular thickness, however, revealed unplausible results (-29.1 + 24.1 % vs. 104.9 + 11.7 %, p < 0.001).In conclusion, HR-pQCT generates pseudo-3D images of historical bones in good quality. Calculation of trabecular number, cortical thickness and cortical bone density reveals plausible results, whereas this is not the case for trabecular bone volume / tissue volume and trabecular thickness. This can be explained by the calculation's method of these bone parameters (Boutroy et al., J. Clin Endocrinol Metab 2005), which is affected by the absence of soft tissue and bone marrow.

Bariatric Surgery is Associated with Increased Fracture Risk Among Veterans *Eileen H. Koh[1.] Tiffany Y. Kim[2.] Hui Shen[2.] Mary A. Whooley[2.] Matthew L. Maciejewski[3.] Theodore S. Z. Berkowitz[4.] Valerie Smith[3.] Lygia Stewart[2.] Anne L. Schafer[2.] [1]University of California, San Francisco, United States. [2]University of California, San Francisco and San Francisco Veterans Affairs Health Care System, United States. [3]Durham Veterans Affairs Health Services Research and Development and Duke University, United States. [4]Durham Veterans Affairs Health Services Research and Development, United States

Despite its metabolic and mortality benefits, bariatric surgery has negative skeletal effects. The Roux-en-Y gastric bypass (RYGB) procedure is associated with increased fracture risk in the general bariatric surgery population, who are predominantly premenopausal women. It is unclear whether postoperative fracture risk is increased in men, and whether patients with obesity who undergo sleeve gastrectomy (SG), now the most commonly performed procedure, are more likely to fracture than nonsurgical patients. We compared fracture risk among US Veterans who underwent bariatric surgery from 2000-2020 at a Veterans Affairs (VA) facility or paid for by VA and matched Veterans with obesity who did not have surgery. Surgical patients were matched 1:3 to nonsurgical patients by age, sex, year, and pre-op BMI. We used ICD codes to capture incident fracture from VA electronic health records, VA purchased care claims, and Medicare claims. Cox proportional hazards models were used to determine the relationship between bariatric surgery and subsequent fracture risk. Our surgical cohort, comprised of 8357 patients [3182 RYGB, 4168 SG, 291 adjustable gastric banding (AGB)], was 70% men with mean age 52+/-10 years and BMI 45+/-7 kg/m2. Compared to 25,057 matched Veterans who did not have surgery, surgical patients had higher baseline rates of obesity-related comorbidities including diabetes (48% vs 36%). During an average 7 years follow-up, surgical patients had higher rates of incident fracture (25.1 vs 13.9 per 1000 person-years). Bariatric surgery was associated with a 67% increased risk of incident fracture (HR 1.67, 95% CI 1.56-1.79, p<0.001) after adjustment for race/ethnicity, geographic location, and comorbidities. Bariatric surgery was also associated with incident hip fracture (HR 2.42, 95% CI 1.97-2.96, p <0.001), spine fracture (HR 1.81, 95% CI 1.60-2.05, p<0.001), and radius fracture (HR 2.36, 95% CI 2.03-2.75, p< 0.001). Compared to matched controls, RYGB was associated with increased risk of fracture (HR 1.91, 95% CI 1.73-2.11, p<0.001), as was SG (HR 1.48, 95% CI 1.31-1.67, p<0.001), but there was no difference in fracture rates between RYGB and SG (p=0.18). There was no evidence for an association between AGB and fracture risk (HR 0.97, 95% CI 0.68-1.40, p=0.88). Our findings show that RYGB and SG are associated with increased risk of fracture in this Veteran population of predominantly older men, including at major osteoporotic fracture sites.

Evaluation of the Mandibular Condylar Bone Microarchitecture in People Living with HIV (PLWH) *Michael Levit[1.] Sunil Wadhwa[1.] Michael Yin[2.] Satoko Matsumura[1.] Shin Jung Hsieh[1.] Karolina Kister[1.] Cleber Silva[1.] Jayesh Shah[3.] Anyelina Cantos[3.] Bruno Bohn[4.] Ryan Demmer[4.] [1]Columbia University College of Dental Medicine, United States. [2]Columbia University, United States. [3]Columbia University College of Physicians and Surgeons, United States. [4]University of Minnesota, School of Public Health, United States

Objectives: People living with HIV (PLWH) have been shown to have lower bone density at the spine, hip and radius. However, whether a similar bone phenotype is seen in craniofacial bones is not known. The goal of this study was to evaluate the bone microarchitecture of the mandibular condyle in PLWH.Methods: We recruited 212 participants, which included 88 (22 men, 66 women) HIV-negative participants and 124 (35 men, 89 women) PLWH on combination antiretroviral therapy with virological suppression from a single academic center. Each participant filled out a validated Temporomandibular Disorder (TMD) pain screening questionnaire and had Cone beam computed tomography (CBCT) of their mandibular condyles. Qualitative radiographic evidence of Temporomandibular Joint Disorders-Osteoarthritis (TMJD-OA) assessment and quantitative microarchitecture analysis of their mandibular condylar bones were conducted with CT Analyzer, Bruker Corp. See attached figure for representative trabecular and cortical isolation.Results: There was no statistically significant difference in either self-reported TMD (PLWH: 7.1% vs HIV negative: 11.8% p=0.27) or in radiographic evidence of TMJD-OA (PLWH: 7.8% vs. HIV-negative: 4.2% p=0.585). Linear regression analysis revealed that positive HIV status remained

significantly associated with increased trabecular thickness (0.611 +/- 0.041 vs 0.582 +/- 0.061;p=0.0001), decreased cortical porosity (5.008% +/- 4.214 vs 8.846% +/- 7.082; p<0.0001) and increased cortical bone volume fraction (0.95 +/- 0.042 vs 0.912 +/- 0.071; p<0.0001) after adjusting for race, diabetes, sex and age.Conclusion: Unlike in long bones, PLWH have increased mandibular condylar trabecular bone thickness and cortical bone volume fraction compared to HIV-negative controls.

Uncovering the Association of Environmental Stressors on Bone Health in Indigenous Guatemalan Children: Exploring the Interplay between Bone Quality, Body Composition, Nutrition, Maternal Health, and Household Characteristics *Michele Monroy-Valle[1], Hassan Vatanparast[2], Ginny Lane[3]. [1]University of Saskatchewan, , [2]Professor. College of Pharmacy and Nutrition/ School of Public Health. University of Saskatchewan, Canada, [3]Assistant Professor. School of Family and Consumer Sciences. University of Idaho, United States

The environment, diet, and maternal health play a fundamental role in bone elongation during childhood. Economic, societal, community, and emotional elements can cause biosocial stress, which reduces bone development. We explored the association between bone quality, body composition, nutrition, maternal health, and household characteristics among 133 Mayan Indigenous children aged 2 to 5 years old residing in Chichicastenango, Guatemala. We cross-sectionally measured bone quality (Speed of Sound m/s) on the left distal radius and midshaft tibia using Quantitative Ultrasound. We measured body composition by bioimpedance with four electrodes. We gathered data on household factors, such as overcrowding, access to drinking water and sanitation, as well as data on mother and child health. We descriptively analyzed the data and performed statistical modelling. We found that 53.0% (n=70) of children had short stature and potential stunting syndrome [49.2% (n=30) of females and 56% (n=40) of boys]. Stunted children were 2.8 (95% CI 1.3, 6) times more likely to have poor bone quality. More than half of the children (61.4%) lived in rural regions, with 33% lacking access to drinking water and sanitary facilities. Children who lived in a home without water or sanitary facilities were 3.1 (95% CI 1.3, 7.0) times more likely to have low bone quality. Almost three-quarters of the stunted children (70%, n=49) had a short mother. Non-stunted children with taller mothers (height over 145 cm) had higher bone quality than stunted offspring. Mother's height was linked with boys', but not girls', bone quality. However maternal body fat mass was linked with higher bone quality among all children, especially girls. Stunted children, whose mothers' fat mass was low, and lived in a food insecure household had the lowest bone quality. Our findings suggest an intergenerational effect on bone quality in the offspring of malnourished mothers. Furthermore, lack of access to drinking water and sanitation, as well as poor living conditions such as overcrowding, limit access to nutritious meals and a low-inflammatory environment that support healthy growth and development. Low maternal fat mass, stunting, and being food-insecure all increase the likelihood of children having poor-quality bones.

Baseline Associations of Age and BMI with Compartmental, Volumetric Bone Mineral Density Tomography in Older Adults Living with Obesity in the INVEST in Bone Health Trial *Delanie Lynch[2], Marjorie Howard[2], Daniel Beavers[3], Erica Lawrence[4], Joshua Stapleton[5], Ashley Weaver[6], Kristen Beavers[3]. [2]Wake Forest University School of Medicine , , [2]Wake Forest University School of Medicine , United States, [3]Wake Forest University, United States, [4]California Pacific Medical Center, United States, [5], , [6]Wake Forest University School of Medicine, United States

Over 50% of older adults (>50 yrs) have low bone mineral density (BMD) and more than 30% are currently living with obesity, with rates rising. Low BMD and obesity both negatively impact overall health and quality of life in the aging population. This study used quantitative computed tomography (QCT) to measure compartmental, volumetric BMD (vBMD) in older adults living with obesity enrolled in a weight loss (WL) trial to explore baseline associations between regional vBMD and age or BMI.The ongoing INVEST in Bone Health trial (NCT04076618) has enrolled 150 older adults (66+/-5 yrs; 69% white; 25% male) living with obesity (34+/-3 kg/m2) to determine effects of a WL intervention with or without weighted vest use or resistance training on bone health. The trial completed enrollment in March 2023 and QCT scans of the hips and lumbar spine were acquired for all participants at baseline. Using a calibration phantom, trabecular and cortical vBMD of the total hip (TH) and femoral neck (FN) and trabecular vBMD of the spine (average of L1-L4) were generated. Analyses were performed using simple linear regression models for the spine and mixed models for the hip, to account for left and right sides. Models explored associations of age and vBMD (adjusted for sex and BMI), and BMI and vBMD (adjusted for sex and age). Pearson's partial correlation was used to analyze relationships between hip and spine vBMD (adjusted for age, sex, and BMI).Greater age (+1 yr) was associated with higher cortical and trabecular vBMD at the hip and spine, but only TH cortical vBMD was significant (+0.9 mg/cm3; p<0.01). Greater BMI (+1 kg/m2) was associated with lower cortical and increased trabecular vBMD for the hip, with strongest associations observed at the FN (cortical: -2.2 mg/cm3; p<0.01; trabecular: +0.9 mg/cm3; p=0.04). Trabecular vBMD of the spine was highly correlated with trabecular vBMD for TH (r=0.76; p<0.01) and FN (r=0.64; p<0.01; see Figure).Unexpectedly, vBMD was positively associated with age, but only significant for TH cortical, which may be due to our relatively active cohort. Consistent with prior studies, BMI was positively associated with trabecular vBMD, likely due to loading from excess adiposity. Regional vBMD measures were highly correlated with each other indicating uniformity across common fracture sites. As the INVEST in Bone Health trial completes follow-up, these outcomes will be explored longitudinally with respect to WL and interventional assignment.

Comparative effects of antihypertensive medications on fracture risk in elderly patients with hypertension *Seung Shin Park[3], Hanna Jang[2], Sung Hye Kong[3], Hyunmook Jeong[3], Siyeon Yi[3], Seung Hun Lee[4], Jeonghoon Ha[5], Kwangsoo Kim[3], Jung Hee Kim[3], SANG WAN KIM[6], Chan Soo Shin[7]. [3]Seoul National University Hospital, Korea, Democratic People's Republic of, [2]Seoul National University Bundang Hospital, Korea, Democratic People's Republic of, [3]Seoul National University Hospital, Republic of Korea, [4]Asan Medical Center, Korea, Democratic People's Republic of, [5], Republic of Korea, [6]Seoul National University College of Medicine, Boramae Medical Center, Republic of Korea, [7]Seoul National University College of Medicine, Republic of Korea

Background:Hypertension and osteoporosis commonly coexist in the elderly, and some antihypertensive medications have been reported to potentially lower the risk of fractures. However, there is limited data comparing the effects of different antihypertensive agents and their combinations on fracture risk. We aimed to investigate the individual and combined effects of antihypertensive drugs on fracture risk in this study.Methods:A total of 28,247 patients who received antihypertensive medications for at least one year between 2008 and 2012 at Seoul National University Hospital were retrospectively reviewed using common data model. Patients were categorized into groups based on their antihypertensive medication use: antiotensin receptor blocker (ARB), calcium channel blocker (CCB), beta blocker (BB), ARB with CCB, ARB with BB, ARB with thiazide, CCB with BB, and ARB with BB

and thiazide, for the purpose of analysis. Fracture risks, defined as major osteoporotic fractures (MOFs), vertebral fractures (VFs), and hip fractures (HFs), were analyzed using the Cox proportional hazard model with adjustments made for age, sex, body mass index, previous history of fractures, secondary osteoporosis-related conditions, diabetes mellitus, drug use, and the use of osteoporosis medications.Results:The number of patients using ARB, CCB, BB, ARB with CCB, ARB with BB, ARB with thiazide, CCB with BB, and ARB with BB and thiazide were 5,515, 7,514, 4,940, 5,022, 1,055, 1,965, 1,874, and 362, respectively. Among the total patient population, females accounted for 50.6%, and the average age and BMI were 65.8 years and 24.5 kg/m2, respectively. Compared to the CCB group, the BB group showed a significantly increased risk of osteoporotic fractures (MOFs) and vertebral fractures (VFs) (Hazard ratio (HR) 1.24, 95% confidence interval (CI) [1.01, 1.52] for MOFs; HR 1.40, 95% CI [1.08, 1.91] for VFs). In contrast to the BB group, the ARB with BB group and ARB with BB and thiazide groups demonstrated decreased HRs for VFs of 0.51 and 0.29, respectively (95% CI [0.28, 0.94] and [0.09, 0.93]). No significant differences in fracture risk were observed between the ARB monotherapy group and the ARB with BB, ARB with CCB, or ARB with thiazide groups (HR 1.07, 1.03, and 0.87 respectively). Conclusion:In hypertensive patients with concomitant osteoporosis, prioritizing the use of ARB and thiazide over BB when selecting medications may help reduce the risk of fractures.

Hypothalamic-Pituitary-Ovarian Axis Suppression Among Women During U.S. Army Basic Combat Training *Kristin Popp[1], Brittany Bozzini[2], Marinaliz Reynoso[2], Katelyn Guerriere[2], Jennifer Coulombe[3], Nicholas Zurinaga[2], Stephen Foulis[2], Katherine Kuhn[4], Mary Bouxsein[5], Nanette Santoro[4], Julie Hughes[6]. [1]Massachusetts General Hospital, , [2]USARIEM, United States, [3]Center for Advanced Orthopedic Studies, Department of Orthopedic Surgery, Beth Israel Deaconess Medical Center, Harvard Medical School, United States, [4]University of Colorado, United States, [5]Beth Israel Deaconess Medical Center, Harvard Medical School, United States, [6]US Army Research Institute of Environmental Medicine, United States

Hypothalamic-pituitary-ovarian axis suppression can lead to poor bone health and increased risk of bone stress injury. Female trainees overwhelmingly (86%) report menstrual cycle changes during 8-10 weeks of U.S. Army Basic Combat Training (BCT). Whether reported menstrual cycles changes reflect hypothalamic-pituitary-ovarian (HPO) axis suppression during BCT is unknown.Female trainees (n=48) who were not using hormonal contraceptives, provided fasted, rested daily first void urine and weekly blood samples and questionnaires during BCT. Luteinizing hormone (LH), follicle stimulating hormone (FSH), and metabolites of estradiol (E1c) and progesterone (Pdg) were measured by chemiluminescent assays (Siemens Centaur XP) and adjusted for urinary creatinine (cr). We used Mann Whitney U tests to compare maximum values of LH, FSH, E1c, and Pdg between women who had evidence of luteal activity (ELA) or no ELA (NELA) during BCT.Trainees were young (21.1+/-4.9yrs), normal weight (23.7+/-2.9kg/m2) women. Most trainees (75%) reported regular menstrual cycles before starting BCT. During BCT, 36 (77%) trainees reported at least one menstrual period, and 41 (87%) reported changes to either menstrual cycle symptoms, length, or frequency. Hormones normalized to a 28 day menstrual cycle are displayed in figure 1. Only seven trainees had menstrual cycles indicating ELA (i.e. presumed ovulation) during BCT, all with shortened luteal phases ranging from 3-10 days in length. Thus, 85% of women showed NELA and 100% of women displayed menstrual cycle dysfunction. Mean peak hormone concentrations were higher in ELA compared to NELA trainees: E1c, ELA 29.6+/-17.9 vs. NELA 16.7+/-7.4 ng/mg cr (p=0.04), Pdg, ELA 2.9+/-1.3 vs. NELA 1.1+/-0.9 µg/mg cr (p=0.0007); and LH, ELA 27.8+/-23.1 vs. NELA 11.6+/-8.5 mIU/mg cr (p=0.01). FSH was not different between ELA 31.0+/-10.6 and NELA 25.9+/-10.3 mIU/mg cr (p=0.2).Our findings reveal that HPO axis suppression with no evidence of luteal activity is very common during BCT and occurs among menstruating women. This suppression is important to consider in efforts to optimize bone health and reduce bone stress injury risk in female trainees.

Androgen Deprivation Therapy increases the risk of clinical fractures in men with Prostate Cancer *Marsha van Oostwaard[2], Caroline Wyers[2], Yes van de Wouw[2], Marc de Jong[2], maud van Maren[2], Maryska Janssen-Heijnen[3], Joop Van Den Bergh[4]. [2]VieCuri Medical Centre, , [2]VieCuri Medical Centre, Netherlands, [3]Maastricht University, Netherlands, [4]VieCuri MC Noord-Limburg and Maastricht UMC,

Androgen Deprivation Therapy (ADT) is known to increase long-term fracture risk in men with Prostate Cancer (PCa) although the risk of clinical fractures, excluding pathological fractures, is not well known. This study aims to evaluate the risk of clinical and pathological fractures in men with PCa treated with ADT compared to those not treated with ADT. Methods: We conducted a cohort study of men diagnosed with PCa between 2014 and 2019. Data was extracted from electronic health records and fractures were radiographically confirmed. Patients were followed from PCa diagnosis date until death, end of study, or fracture, whichever came first. Follow-up time was divided into 30-day intervals and exposure (current, past or non-ADT use) was determined at each interval based on prescription data. Current ADT use was further stratified by duration of ADT use (0-182 days, 183-730 days, and > 730 days). Cause-specific Cox proportional hazard models were used to estimate the risk of all fractures, the risk of clinical and pathological fractures separately and the risk of mortality with current use of ADT vs. non-ADT use. All analyses were adjusted for age and stage of disease. Results: We included 225 current or past ADT users and 244 non-users, with a mean age of 70.5 (+/-8.3) years. Overall, 30 clinical and 12 pathological fractures during ADT use, and 18 and 0 during non-ADT use were observed, respectively. Current ADT use was associated with an increased risk of all (clinical and pathological) fractures (HR: 5.11; 95%CI: 2.34-11.14) as compared to non-ADT use, while past ADT use was not. Stratification of current ADT use by duration showed an increased risk of all fractures in all ADT duration categories. Current ADT use was not associated with mortality (HR: 1.29; 95%CI: 0.59-2.84) while past use was associated with mortality (HR: 3.59; 95%CI: 1.78-7.24). Associations were similar when only clinical fractures were studied (current ADT use HR: 3.62; 95%CI: 1.57-8.32). The association with pathological fractures could not be studied due to no events during non-ADT use. Conclusion: In addition to the increased risk of pathological fractures, current ADT use was associated with an increased risk of clinical fractures compared to non-ADT use. Therefore, attention is needed for prevention of clinical fractures immediately at the start of ADT.

Associations Between the Changes in Gut Microbiota and Bone and Muscle Outcomes After Sleeve Gastrectomy *Angela Yang[1], Julie-Catherine Coll[2], Thibault Varin[3], Serge Simard[3], Suzanne Morin[4], Fabrice Mac-Way[5], André Tchernof[6], Bettina Willie[4], Stéfane Lebel[7], André Marette[3], Claudia Gagnon[8]. [1]Universite Laval, , [2]CHU de Québec Research Centre, Quebec Heart and Lung Institute Research Centre, Canada. [3]Quebec Heart and Lung Institute Research Centre, Canada. [4]McGill University, Canada. [5]CHU de Québec Research Centre, Department of Medicine, Laval University, Canada. [6]Quebec Heart and Lung Institute Research Centre, Department of Medicine, Laval University, Canada. [7]Quebec Heart and Lung Institute Research Centre, Department of Surgery, Laval University, Canada. [8]CHU de Quebec, Universite Laval, Canada

The mechanisms leading to bone and muscle loss after sleeve gastrectomy (SG) remain unclear. We aimed to determine whether changes in the gut microbiota following SG are associated with this bone and muscle loss.This is an exploratory analysis of a multicentre prospective cohort study, in which 70 participants with severe obesity had the following parameters measured before and one year after SG: lumbar spine, total hip, and femoral neck areal bone mineral density (aBMD) and whole-body lean mass by dual-energy X-ray absorptiometry; lumbar spine, total hip, femoral neck, tibia, and radius volumetric BMD (vBMD), bone strength (maximum cross-sectional moment of inertia [CSMI] and maximum section modulus [Z]), and mid-femur muscle cross-sectional area by quantitative computed tomography; serum bone turnover markers (C-terminal crossed-linked telopeptide of type 1 collagen [CTX], procollagen type 1 N-terminal propeptide [P1NP], osteocalcin); lower limb absolute and relative muscle strength by isometric dynamometry. Gut microbiota from stool samples was analyzed by 16S rRNA gene sequencing at baseline and one year after SG. Results are presented as percentage or mean+/-SD. Linear regression analyses adjusted for age and sex were used to assess the associations between microbial, bone, and muscle parameters.A preliminary sample of 19 participants (79.0% women [26.7% postmenopausal], 57.9% with type 2 diabetes, mean age 45.3+/-9.5 years, mean BMI 40.1+/-0.6 kg/m2 at baseline) was analyzed. One year after SG, weight (-26.3+/-6.1%), aBMD (-6.4 to -8.5% depending on skeletal sites), vBMD (-1.0 to -7.4% depending on skeletal sites), whole-body lean mass and mid-femur muscle cross-sectional area as well as lower limb absolute muscle strength all decreased significantly (Table). Bone strength parameters did not change. All serum bone turnover markers increased significantly. Alpha diversity, represented by Shannon (p=0.04) and Simpson (p=0.02) indices, increased significantly while beta microbial diversity did not change (p=0.60).In this preliminary sample, significant associations were identified between bacteria genera and some bone parameters, but not between microbial and muscle parameters. Further analysis of the additional participants is ongoing to confirm that associations observed between gut microbiota composition and bone outcomes after SG persist in the larger cohort.

Association of Lower Leg Arterial Calcification with Tibial Bone Microarchitecture and Fracture History in Older Men *BITA ZAHEDI[3], Fjola Johannesdottir[2], Trinity Tedtsen[3], Sheena Patel[4], Peggy Cawthon[5], Andrew Burghardt[6], Kristine Ensrud[7], Charles Ginsberg[8], Nancy Lane[9], Mary Bouxsein[10], Elaine Yu[3]. [3]Massachusetts General Hospital, , [2]Beth Israel Deaconess Medical Center & Harvard Medical School , , [3]Massachusetts General Hospital, United States. [4], , [5]San Francisco Coordinating Center, United States. [6]University of California, San Francisco, United States. [7]University of Minnesota and Minneapolis VA Health Care System, United States. [8]UCSD, , [9]University of California, Davis Medical Center, United States. [10]Beth Israel Deaconess Medical Center, Harvard Medical School, United States

Background: Bone is a highly vascular tissue and it has been postulated that disordered bone blood flow may directly contribute to poor skeletal health. Prior studies have found associations between cardiovascular disease (CVD) and decrease in axial bone mineral density (BMD), although locoregional effects of arterial calcification on bone microarchitecture are not clear. Recently, post-processing analysis of high resolution peripheral quantitative computed tomography (HR-pQCT) has been developed to quantify lower leg arterial calcification (LLAC) with great validity and reliability. The aim of this study is to determine whether LLAC in older community-dwelling men is associated with deficits in volumetric bone mineral density (vBMD) and microarchitecture at the distal tibia. Methods: 1717 men from the Osteoporotic Fractures in Men (MrOS) study completed tibial HR-pQCT with assessment of vBMD, bone microarchitecture, and presence of LLAC. Clinical covariates and medical history were collected, along with spine and hip BMD by DXA and prevalent fracture. Linear and logistic regression were performed with adjustments for age, site, race, body mass index (BMI), self-reported diabetes, cardiovascular disease (CVD), and chronic kidney disease (CKD). Results: Men with LLAC (n=887, 52%) and without LLAC (n=830, 48%) had similar age (84 +/- 4 yrs), BMI (26.8 +/- 3.8 kg/m^2), race (90% White), alcohol use and spine and hip BMD. Men with LLAC were less physically active, more likely to report diabetes and CVD, but less likely to report ever smoking. Furthermore, the LLAC group had slightly lower cortical vBMD (-1.5%) and higher cortical porosity (+5.5%) at the tibia, which persisted after adjustment for covariates (Table 1). Total vBMD and trabecular parameters were largely similar between groups. Men with LLAC were more likely to have prior fracture (OR 1.26, 95%CI 1.03-1.54) even after multivariate adjustment. Conclusion: In this large cohort of older community-dwelling men, we demonstrated a small but significant negative correlation between presence of LLAC and cortical bone microarchitecture at the tibia. LLAC was also associated with prevalent fracture history. Further studies are needed to understand the mechanism underlying the association of vascular calcifications and bone outcomes.

Treatment With Monthly Romosozumab Injections Increases Areal Bone Mineral Density at the Lumbar Spine and Hip in Women With Chronic Spinal Cord Injury *W. Brent Edwards[1], Laura E. Crack[1], Tudor Muresan[1], Narina Simonian[2], Thomas J. Schnitzer[2]. [1]University of Calgary, Canada. [2]Northwestern University Feinberg School of Medicine, United States

Sublesional bone loss is a known complication of spinal cord injury (SCI) with low bone mineral density (BMD) and increased fracture risk persisting into the chronic phase of injury. While existing literature focuses on pharmaceutical treatment options to prevent bone loss in acute SCI, limited investigations have examined potential therapies to increase BMD in chronic SCI. Romosozumab, a monoclonal antibody that inhibits sclerostin, has illustrated significant bone growth in pre-clinical models and among able-bodied post-menopausal clinical populations. The purpose of this study was to examine the efficacy of romosozumab to increase BMD in women with chronic SCI and an inability to ambulate. Twelve women with a mean (SD) age of 45.4 (9.1) years and injury duration of 15.1 (11.2) years, were administered monthly subcutaneous injections of romosozumab (210 mg) for one year. Areal BMD of the lumbar spine and hip (total hip and femoral neck) were measured at baseline and after 6 and 12 months using dual energy x-ray absorptiometry (DXA). The study is on-going and currently nine of the 12 participants have completed all aforementioned data collection. A preliminary analysis was conducted using longitudinal mixed-effects models to examine

Sunday Orals

the effect of one year of romosozumab treatment on DXA-derived areal BMD measures. Areal BMD at the lumbar spine significantly increased (p<0.001) by an average of 6.1 (3.6)% and 9.3 (3.1)% after 6- and 12-months, respectively (Fig. 1). DXA-derived BMD at the total hip increased (p<0.001) with average gains of 2.2 (2.6)% and 4.1 (3.1)% after 6- and 12-months, respectively. Results were similar when isolating the femoral neck (p=0.014), which increased by an average of 1.8 (6.9)% at 6-months and 4.6 (4.9)% at 12-months. These results are comparable to the treatment efficacy of romosozumab for post-menopausal osteoporosis, which induced an annual increase in areal BMD of approximately 17% at the lumbar spine and 5% at the hip1. These preliminary findings demonstrate that treatment with romosozumab in women with chronic SCI increases areal BMD at the lumbar spine and hip, similar to effects in post-menopausal osteoporosis in able-bodied women. On-going data collection in this clinical trial will lead to further analysis with a larger sample size, and evaluation of bone mineral at the knee and hip using computed tomography.[1] Ishibashi H et al. (2017). Bone. 103:209-215

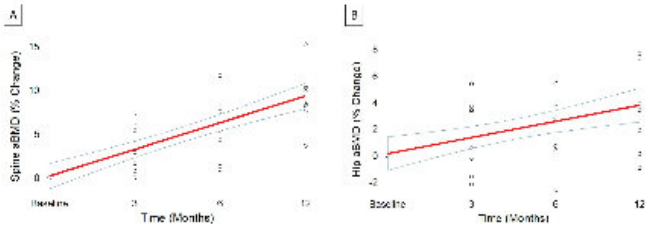

Figure 1. Individual [n=9] and average (95% CI) percentage change in lumbar spine (A) and total hip (B) areal bone mineral density (aBMD) throughout 12 months of treatment with subcutaneous injections of romosozumab (210 mg)

Hip Fractures in Adults with Schizophrenia in Ontario: a Population-based Repeated Cross-sectional Study *Hina Ansari[1], Susan Jaglal[2], Angela M Cheung[3], Paul Kurdyak[4]. [1]Institute of Health Policy, Management and Evaluation, Canada. [2]Toronto Rehabilitation Institute, University Health Network, Canada. [3]Department of Medicine and Joint Department of Medical Imaging, University Health Network, Canada. [4]Centre for Addiction and Mental Health, Canada

Purpose: Individuals with schizophrenia may experience a higher burden of hip fractures. Our study objectives were to describe sociodemographic and clinical characteristics of hip fracture patients with schizophrenia, and quantify their sex-specific annual hip fracture rates relative to the general population.Methods: This repeated population-based, cross-sectional study leveraged multiple individually linked health administrative databases for patients in Ontario, Canada. We included patients aged 40 to 105 years with hip fracture-related hospitalization between April 1, 2009, and March 31, 2019. Schizophrenia diagnosis was ascertained using a validated algorithm. Primary outcome measures were sex-specific age-standardized annual hip fracture rate per 10,000 individuals, and annual percent change in age-standardized rates. Rates were adjusted to the 2011 Ontario population; annual percent change was evaluated using Joinpoint regression.Results: We identified 109,908 index hip fractures with a median[IQR] patient age of 83[75-89] years and 31.4% males. Hip fracture patients with (n=4,251) vs without (n=105,657) schizophrenia were younger at index event [male median[IQR] age: 73[62-83] vs 81[71-87] years (standardized difference, 0.46); female median[IQR] age: 80[71-87] vs 84[77-89] years (standardized difference, 0.32)]. A higher proportion of those with vs without schizophrenia had frailty (54% vs 34%; standardized difference, 0.40), and previous fragility fractures (24% vs 19%; standardized difference, 0.11). The overall age-standardized rate per 10,000 individuals with vs without schizophrenia was 37.5 (95% CI: 36.4-38.6) vs 16.0 (95% CI: 15.9-16.1). Age-standardized rates were threefold higher in men with vs without schizophrenia [31.0 (95% CI: 29.5-32.6) vs 10.1 (95% CI: 9.96-10.2)], and more than twofold higher in women with vs without schizophrenia [43.4 (95% CI: 41.9-44.9) vs 21.4 (95% CI: 21.3-21.6)]. Rates in men with schizophrenia surpassed that of women in the general population. Overall, Joinpoint regression analysis identified a steady annual decrease of 0.7% (95% CI: -1.1% to -0.3%) for both study groups.Conclusions: Findings suggest that individuals with schizophrenia experience an earlier onset and substantially higher burden of hip fractures, with implications for targeted fracture prevention and optimization of bone health management over the course of their psychiatric illness.

PD-L1 Expressing Myeloid Cells Promote Bone Marrow Immunosuppression and Osteoclastogenesis with Diet-Induced Obesity *Samantha Costa[1], Sergey Ryzhov[2], Moustapha Kassem[3], Dr. Clifford ROsen[4]. [1]MaineHealth Institute for Research , United States. [2]MaineHealth Institute for Research, United States. [3]Odense University Hospital, Denmark. [4]Maine Medical Center, United States

Programmed death ligand 1 (PD-L1) when combined with PD-1 inhibits immune responses and promotes self-tolerance by modulating T-cell function. Previous studies have investigated aberrant PD-L1 expression in tumor-bearing models. Recently, we identified a novel population of PD-L1 expressing myeloid cells within the bone marrow of obese, non-tumor bearing mice. However, the role of PD-1/PD-L1 signaling in osteoclast differentiation resulting in obesity-related bone loss has yet to be explored. We hypothesized obesity-induced bone loss is linked to PD-1/PD-L1 signaling through a pro-osteoclastogenic mechanism. Starting at 8 weeks of age, C57BL/6J mice were fed a high-fat diet (HFD, 60% kcal) or sucrose-matched low-fat diet (LFD, 10% kcal) for 12 weeks. After 12 weeks of HFD-feeding, pre-determined parameters based on body measurements (i.e., body weight >40g and percent body fat >32%) were used to classify obese mice. Compared to LFD-fed mice, obese mice had an increase in MHCIInegPD-L1+ myeloid cells (fully defined as CD11bhighCD11chighMHCIInegF4/80+PD-L1+, p<0.0001). The increase of PD-L1 coupled with the loss of MHCII expression negatively affected T-cell activation and increased immunosuppressive CD39 and CD73 expression (p=0.0019 and p=0.0012). In vitro PD-L1 blockade suppressed osteoclast differentiation (p=0.014), suggesting the PD-1/PD-L1 axis mediates osteoclastogenesis. In addition, PD-1 expressing osteoclast precursors (defined as [B220/CD3/NK1.1]negc-kit+CD115+CD11blowPD-1+) were increased in obese mice compared to LFD-fed mice (1.34-fold higher than LFD, n=10 mice/group, p=0.0042). TRAP staining and histomorphometric analyses revealed obese mice had an increase in osteoclasts (1.82-fold higher than LFD, p=0.0070) and enhanced eroded surface, while no significant changes in osteoblast number and mineralizing surface were observed. As a result, obese mice had decreased femoral (Tb.BV/TV, obese 10.76% vs LFD 12.13%, n=7 mice/group, p=0.020) and tibial (Tb.BV/TV, obese 13.76% vs LFD 20.34%, n=8-10 mice/group, p<0.0001) trabecular bone mass as well as decreased cortical area (Ct.Ar/T.Ar, obese 56.59% vs LFD 58.61%, n=8-10 mice/group, p=0.0245). In summary, obesity creates an immunosuppressive bone marrow microenvironment through increased PD-1 and PD-L1 expression in myeloid and myeloid lineage cells that results in osteoclast-driven bone loss. The impact obesity-induced PD-1/PD-L1 signaling has on osteoclast overactivation remains to be elucidated.

The Role of Cathelicidin Antimicrobial Peptide in Bone Fracture Repair and Aging *Tuyet Nguyen[1], Tomasa Barrientos de Renshaw[1], Bridgette Furman[1], Puvi Nadesan[1], Vijitha Puviindran[1], Savanna Ma[1], Koji Ishikawa[1], Benjamin Alman[1]. [1]Duke University, United States

The bone repair process becomes less efficient with age resulting in improperly healed fractures, a condition which positively correlates with lower quality of life and higher mortality in geriatric patients. Past murine heterochronic parabiosis experiments have shown that circulatory factors from young mice are able to rejuvenate the fracture repair process in aged animals. Recent studies have specifically identified macrophages as a critical component for this rejuvenated healing phenomenon. Single cell RNA sequencing of bone marrow cells post-injury reveals a unique young macrophage subpopulation. Cathelicidin antimicrobial peptide (Camp) is one of the upregulated genes within this novel young cluster. Previously, Camp has been studied in the context of host response against microbial pathogens and as a therapeutic carcinogenic target, but its role in fracture repair and aging has not been well explored. Through microCT analysis, we have found that the Camp global knockout mouse has poor fracture healing, comparable to older individuals. Additionally, rCAMP administration to primary bone marrow cells from old mice cultured in osteogenic media demonstrates a potential role in promoting osteogenesis. These and future experiments will address the gap in understanding of how macrophage-secreted proteins affect the bone healing process and how this interaction is altered with age.

Inflammasome activation is an important mechanism in chemotherapy-induced bone loss *Chun Wang[1], Gabriel Mbalaviele[2]. [1]Division of Bone and Mineral Diseases, Washington University School of Medicine, United States. [2]Washington University in St. Louis School of Medicine, United States

Doxorubicin is a widely used chemotherapy drug for the treatment of a variety of tumors including breast cancer. Despite its success in improving survival rates of cancer patients, it causes deleterious side effects, including bone marrow toxicity, neutropenia, irreversible heart muscle damage, osteoporosis, and fracture risk, but the underlying mechanisms remain unknown. We hypothesized that doxorubicin causes DNA damage, which leaks to the cytoplasm, and cell death, which releases DNA to the extracellular environment. We further hypothesized that mislocalized DNA is sensed by inflammasomes, intracellu-

lar protein complexes that propagate inflammation through various mechanisms, including the maturation and secretion of IL-1?. To test these ideas, we used a non-tumor-bearing mouse model, which allowed the assessment of direct tissue off-target effects of this drug in the absence of tumor confounding outcomes. A single injection of 5 mg/kg doxorubicin to wild-type (WT) mice caused NETosis, a form of neutrophil cell death that follows the release to the extracellular space of genomic DNA and granular contents known as neutrophil extracellular traps (NETs). Specifically, doxorubicin administration increased serum levels of NETosis markers such as citrullinated histone 3 and myeloperoxidase. This response correlated with cytopenia, elevated IL-1? serum levels, increased osteoclast number (N.Oc/BS: vehicle = 4.84+/-0.43; doxorubicin = 12.53+/-1.56), and bone loss (BV/TV: vehicle = 29.21+/-3.93%; doxorubicin = 12.29+/-1.82%). Since damaged or mislocalized DNA is mainly detected by inflammasomes assembled by AIM2 or NLRP3 sensors, we determined their role in doxorubicin actions. Consistent with our hypothesis, doxorubicin osteopenic effects were attenuated in animals lacking AIM2 inflammasome or NLRP3 inflammasome, to some extent (BV/TV: WT = 12.29+/-1.82%; Aim2-/- = 23.33+/-4.05%; Nlrp3-/- = 16.68+/-2.05%). Thus, off-target actions of doxorubicin cause inflammasome activation, a response that ultimately, leads to bone loss.

Systemic versus local immune and inflammatory responses to bone fracture *Maryam Rahmati[1], Robert Charles Henry Gresham[2], Kent Leach[3], Mark A Lee[3], Augustine Mark Saiz[3]. [1]Department of Orthopaedic Surgery, UC Davis Health, 4860 Y Street, Suite 3800, Sacramento, CA, 95817, USA , United States, [2]Department of Orthopaedic Surgery, UC Davis Health, 4860 Y Street, Suite 3800, Sacramento, CA, 95817, USA,Department of Biomedical Engineering, University of California, Davis, Davis, CA, 95616, USA , United States, [3]Department of Orthopaedic Surgery, UC Davis Health, 4860 Y Street, Suite 3800, Sacramento, CA, 95817, USA, Department of Biomedical Engineering, University of California, Davis, Davis, CA, 95616, USA , United States

Bone fracture is a major cause of physical disability, quality of life impairment and global socio-economic burden. Providing new treatments to guide bone-healing processes toward regeneration relies on our understanding of the fundamental mechanisms and the key stimulators of fracture healing. There is growing evidence that the homeostasis of the immune system state is crucial for directing bone tissue healing mechanisms. Although some studies have reported that the induced immune responses caused by tissue injury direct wound healing; there is still a knowledge gap in the literature regarding the cellular phenotype of immune responses to the bone fracture at earlier and later time points. Therefore, we aimed to fill this knowledge gap by studying the local versus systemic immune responses to femur fracture at earlier and later time points in mice using flow cytometry. We induced blunt femur fracture in mice using a fracture apparatus and after 0 h, 6 h, 12 h, 24 h, 72 h & 3W collected femur, lung, and bone marrow form the injured and healthy mice. After obtaining a single cell suspension from all tissues, we stained our cells using fluorophore markers for different immune cells and used a BD “Fortessa” 18-color cytometer. We also checked the expression of pro-inflammatory cytokines using a 20-plex inflammatory Luminex panel. Our data demonstrated that after femur fracture there was a higher number of live cells in the injured mice compared to the healthy ones; however, this difference was only significant systemically (in lung and bone marrow), indicating the key role of systemic immune in directing fracture healing. In addition, at the fracture site, the CD 45+ immune cells significantly increased after 6 h of injury and continued to increase throughout the study time. B and T cells, myeloid cells, dendritic cells, and macrophages increased significantly after 72 h. Neutrophils increased significantly after 12 h of injury. Although systemically, B and T cells did not change significantly over time in the injured group compared to the healthy mice, the number of neutrophils increased significantly in the first 12 h systemically and decreased to the healthy level at later time points. These data identified key differences between systemic and local immune responses to bone fracture and addressed the importance of both systems in directing fracture healing.

Dynamic Transcriptional Cell Atlas of Immune Cell Lineage during Alveolar Bone Healing *Weimin Lin[1], Quan Yuan[1]. [1]Sichuan University, China

The bone marrow microenvironment is mainly composed of immune cells and stromal cells that play an important role in bone healing. Although various immune and stromal cell populations have been identified in mouse bone marrow, the dynamics of immune cell populations and how they crosstalk with bone marrow stromal cells during bone healing process still remain unclear.Alveolar bone defect caused by tooth extraction is one of the most common bone injuries in clinical practice. In this study, we used mice alveolar bone defect after molar extraction as a model to explore the dynamic changes of immune cell population during bone healing. Single-cell RNA sequencing was used to identify the immune cell populations in injured bone tissue, including neutrophils, monocyte-macrophages, T cells, B cells, and plasma cells. We observed a rapid increase in T cell population on the 1th day after injury, while their proportions returned to pre-injury levels by the 7th day. Further subcluster analysis revealed that NKT cell cluster accounted for the highest proportion of T cells, and the number of NKT cell subsets also increased on the 1th day after injury. After co-culturing NKT cells with MSCs in vitro, we found that the osteogenic differentiation potential of MSCs was inhibited. After deleting NKT cells by depletion antibody or gene knockout, alveolar bone injury repair process was accelerated. Differential gene analysis indicated that the expression level of Cxcl2 in NKT cells was significantly increased on the 1th day after injury compared with that before injury. Reduction of Cxcl2 by neutralizing antibody or gene knockout could improve the bone healing process. Finally, we designed a porous hydrogel which could release drugs quickly in the early stage and loaded it with NKT cell depletion antibody then applied it locally for alveolar bone repair. Compared with systemic administration, local hydrogel administration could achieve the deletion of NKT cells and accelerate the repair of alveolar bone, while avoiding other potential side effects of systemic administration.In summary, our study revealed a dynamic immune microenvironment during bone injury repair and found that NKT cell populations can impair bone healing by secreting Cxcl2. Deleting NKT cells or reducing the expression level of Cxcl2 can accelerate the repair of bone damage, which reveals the important role of NKT cells in the process of bone repair.

SUN-098

Eosinophils counteract osteoclast-mediated bone degradation via the secretion of eosinophil peroxidase *Darja Andreev[1], Georg Schett[1], Aline Bozec[1]. [1]Department of Internal Medicine 3 - Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen (UKER), Erlangen, Germany. , Germany

A healthy skeleton relies on a balance between bone-forming osteoblasts and bone-resorbing osteoclasts. A shift towards increased osteoclast number and/ or activity can therefore lead to bone loss with increased fracture risk. Hormonal imbalance or an inflammatory environment, as in rheumatoid arthritis (RA), often favors osteoclast differentiation through an overproduction of proinflammatory cytokines and receptor activator of nuclear factor ?B ligand (RANKL) by adaptive immune cells. Far less is known about immune cells and mediators that inhibit osteoclast development. Most consistently, however, Type-2 immunity-related cytokines have been reported to downregulate osteoclasts. Interestingly, these cytokines are highly secreted by eosinophils. Although eosinophils are mainly associated with helminth infection and allergic disease, in recent years several publications shed light on the homeostatic functions of these cells. Hitherto, the impact of eosinophils on bone homeostasis is completely elusive.Herein, we demonstrate that eosinophils, classical innate immune cells, decrease osteoclast differentiation and activity. Mechanistically, eosinophils release eosinophil peroxidase (EPX) that reduces the level of reactive oxygen species (ROS) in osteoclast progenitors, thereby inhibiting RANKL-mediated downstream signaling. Thus, eosinophil deficiency and subsequent EPX loss is associated with increased osteoclast numbers, leading to amplified pathological bone degradation like postmenopausal osteoporosis and arthritis-induced bone depletion. In contrast, hyper-eosinophilia with enhanced EPX protects from osteoporosis and inflammation-mediated bone loss by impairing osteoclast formation. Likewise, therapeutic treatment with EPX during the course of arthritis reduces the number of osteoclasts and as a result mitigates inflammatory bone turnover. This mechanism is also reproducible and highly relevant in human as a high eosinophil number is associated with increased bone mass in healthy subjects and especially in RA patients. Altogether, eosinophils represent a novel link between the innate immune system and bone, resembling an intrinsic immune-mediated brake of excessive osteoclast formation and bone resorption through the secretion of EPX.

Bioengineered trabecular bone organoid to recapitulate crosstalk between bone and marrow *Yongkuk Park[1], Jungwoo Lee[2]. [1]University of Massachusetts Amherst, , [2]University of Massachusetts-Amherst, United States

Trabecular bone marrow is a multi-functional dynamic tissue that plays a crucial role in maintaining the mechanical structure and mineral homeostasis of the skeleton and supporting continuous blood-forming processes. In vitro recapitulation of trabecular bone marrow function can greatly improve our understanding of the integrated bone and blood and offer therapeutic potential. However, it remains a critical challenge to reproduce hard bone and soft marrow tissue complexity in an integrated platform while maintaining their functional crosstalk for an extended period. Here, we report a modular bioengineered trabecular bone marrow model that effectively represents the complexity of bone and marrow tissues, functioning as an integrated organoid. For the 3D lamellar bone model, we used osteoid-inspired demineralized bone paper (DBP), a 20 um thick section of demineralized bovine bone matrix. The DBP laminated with water-soluble polymer was tailored to be a woven strip. After seeding osteoblasts, a DBP strip was rolled to form a 3D trabecular bone model having a lamellar bone structure with subsurface osteocytes and surface osteoblasts. For the semi-solid marrow model, we utilized a porous hydrogel scaffold mimicking bone marrow sinusoids. We prepared scaffolds having two pore sizes: 500-600 um and 75-100 um. Coating the hydrogel scaffold with type I collagen facilitated bone marrow stromal cell adhesion, while the spherical pore cavities allowed for hematopoietic cell expansion when supplemented with hematopoietic cytokine cocktails. Expanded hematopoietic cells, along with stromal cells, are readily retrieved from larger pores while hematopoietic cells within smaller pores

remain and become the source of replenishment. We then integrated the separately prepared trabecular bone and marrow models, allowing osteogenic cells to provide long-term hematopoietic support in the bone marrow cells. The mobilization and attraction of hematopoietic cells were recapitulated based on osteoblasts' metabolic states. Finally, as a proof-of-concept study, we demonstrated in vitro bone marrow transplantation via a simulating chemotherapy-based preconditioning regime and then introduced new bone marrow cells. Our modular biomaterial strategy offers a promising strategy to recapitulate the complexity and functionality of bone and marrow tissue to study various aspects of osteogenic and hematopoietic cell biology within trabecular bone cavities.

SUN-100

Recapitulating acute myeloid leukemia (AML) phenotypes in vitro using a 3D model of the bone marrow microenvironment (BMME) *AZMEER SHARIPOL[1], Maggie Lesch[2], Celia Soto[1], Benjamin Frisch[3]. [1]University of Rochester, [2]University of Rochester Medical Center, United States. [3]University of Rochester School of Medicine and Dentistry, United States

Acute myeloid leukemia (AML) is an aggressive blood cancer characterized by the uncontrolled expansion of dysfunctional myeloid progenitor cells in the bone marrow (BM). AML-driven dysregulation of the BM microenvironment (BMME) leads to loss of normal hematopoiesis and BM failure. With the median diagnosis age of 68 and the growing aging population, AML cases are projected to climb substantially. The standard care for the majority of patients, introduced in the 1970s, results in an abysmal 5-year survival rate of ~30%. The lack of therapeutic advancement is partly due to the challenging task of recapitulating the signaling between AML cells and the BMME components in vitro such as the osteoblastic, mesenchymal stromal (MSC), and endothelial cells, and the matrix. To bridge this gap, our lab aims to develop AML-on-chip models (AML-chip) to study BMME dysregulation in vitro and as a tool to identify new therapeutic targets. Previously, we developed a murine BMME-chip model containing mineralized osteoblastic and flow-induced endothelial components using Emulate Chip-S1™ that can maintain the long-term function of hematopoietic stem and progenitor cells (HSPC) for at least 14 days in vitro (Sharipol et al., 2022). To develop the AML-chip, we cultured AML cells isolated from blast crisis chronic myelogenous leukemia (bcCML) mice in the marrow component of the BMME-chip with MSC, HSPC, and fibrin-hydrogel. At day 14, AML cells were maintained at 29.00+/-2.35% equivalent to disease burden at advanced stages of AML. Flow cytometry showed a 4-fold increase in HSPC in AML-chip, similar to in vivo, which may indicate loss of differentiation. Similar to in vivo experiments, we found that osteoblastic function is lost in AML-chip as shown by reduction of osteocalcin gene expression at day 7 and 14 (41.10+/-13.50% and 16.60+/-5.00% respectively compared to BMME-chip, p=0.04). This finding is reflected in the decrease of mineralization of the osteoblastic cells observed via histochemical imaging. We have previously reported that the chemokine CCL3 is elevated in AML patients as well as murine models, and that elevated CCL3 inhibits osteoblastic function. Strikingly, we found elevated levels of CCL3 in the effluent of AML-chip compared to BMME-chip (918.49+/-192.54 pg/mL and 498.73+/-79.05 pg/mL, p=0.003). Our results indicate that AML-chip can recapitulate the phenotypes reported in vivo, and supports the reliability of our system to recapitulate human AML in future experiments.

Inhibition of NF-?B Inhibitor Alpha (I?B?) Reduces Type H and L Skeletal Blood Vessels in a Glucocorticoid-Induced Osteotoxic Mouse Model *Sisir Kumar Barik[1], Weixin Zhang[1], Arryn D Otte[1], Janet L Crane[1]. [1]Johns Hopkins University, United States

Osteoporosis and osteonecrosis are well-described adverse effects of chronic glucocorticoid (GC) use; a unifying pathophysiologic change is decreased bone vasculature. Our previous study on young GC-induced osteotoxic (GIO) WT (C57BL/6J) mouse model showed disruption of skeletal angiogenesis through transrepression of nuclear factor kappa B (NF-?B)-mediated preosteoclast (POC) derived platelet-derived growth factor-BB (PDGF-BB) transcription. To further delineate the intracellular signaling mechanism of GC-suppression of angiogenesis, we are disrupting the GC-NF?B-Pdgfb pathway in osteoclasts. We have initially verified the GIO phenotype in GC receptor (GR) floxed (Nr3c1fl/fl) mice intraperitoneally injected with methylprednisolone daily (20 mg/m2/day) or vehicle (veh) for 2, 4, and 6 weeks (n=5-8/group/time point) beginning at postnatal day 14 and further characterized the changes in blood vessels. Micro-CT analysis showed that GIO Nr3c1fl/fl mice have significantly reduced BV/TV at all age groups compared to veh-treated mice. Co-immunostaining at the distal femurs showed reduced CD31hi Emcnhi (Type H vessels) at the metaphyseal region, along with decreased branch points Emcnlow (Type L vessels) in GIO Nr3c1fl/fl mice relative to veh-treated littermates at all age groups. Comprehensive 3D analysis of Type H vessels showed a significant reduction in the vessel diameter, length, area, and volume in GIO Nr3c1fl/fl mice compared to veh-treated mice. Specifically, Type H Vessels were found to be largest in the mid-metaphyseal region and the cortex, with thinner vessels in the angiogenic region towards the growth plate in GIO Nr3c1fl/fl mice. Moreover, thinner vessels were noted at the transition into the diaphysis in GIO Nr3c1fl/fl mice at all the time points. In contrast, veh-treated mice showed a significantly larger volume of Type H vessels identified with CD31hi Emcnhi and time-dependently increased vessel diameter, length, area, and volume nearest to the growth plate, which is the region of angiogenesis. Gene expression analysis on canonical and non-canonical NF-?B pathways from long bones of Nr3c1fl/fl mice showed inhibition of NF-?B inhibitor alpha (I?B?) after 6 weeks, suggesting chronic GC negatively regulates NF-?B signaling. Further experiments disrupting Nr3c1-/- in the osteoclast lineage will help explain the effect of GCs on skeletal angiogenesis and its role in bone formation and development.

The MIP-1?/HMGB1 Signaling Axis Regulates Osteocyte RANKL expression in Multiple Myeloma *ARIC ANLOAGUE[2], MANISH ADHIKARI[2], HAYLEY SABOL[2], Sharmin Khan[3], G. David Roodman[4], Teresita Bellido[5], Jesus Delgado-Calle[6]. [2], [2], United States. [3]University of Arkansas for Medical Sciences, Physiology and Cell Biology, United States. [4]Indiana University, United States. [5]University of Arkansas for Medical Sciences , United States. [6]University of Arkansas for Medical Sciences, United States

Multiple myeloma (MM) is a hematologic cancer characterized by the uncontrolled growth of malignant plasma cells in the bone marrow and devastating bone disease. Bone disease is a hallmark of MM. Reciprocal communication between MM cells and cells of the tumor microenvironment (TME) increases osteoclast differentiation and drives bone destruction, which persists in MM patients even during remission. Current therapies, including bisphosphonates and Denosumab (anti-RANKL antibody), reduce skeletal related events in patients with MM osteolytic disease, but long-term suppression of bone remodeling using these drugs has adverse side effects. Thus, identifying new targets to restore bone resorption to physiological levels is imperative to improve bone health and reduce the potential negative side effects in MM patients. Here we explored the molecular mechanisms regulating RANKL, a pro-osteoclastogenic cytokine essential for osteoclast formation, in the MM TME. Earlier work demonstrated that osteocytes are part of the TME and thus we hypothesize that MM-derived factors stimulate RANKL expression in osteocytes, an abundant cellular source of this cytokine in bone. Treatment of osteocyte-like cells (MLOA5/Y4) with 25% conditioned media (CM) from human JJN3 MM cells or murine 5TGM1 MM cells resulted in a ~2-fold increase in RANKL expression. MIP-1a is produced by MM cells, increases osteoclastogenesis, and it is associated with poor outcomes. Because osteocytes expressed the MIP1? receptors CCR1/3/5, we next investigated whether MM-derived MIP1? regulates RANKL in osteocytes. Recombinant MIP1? increased by ~2-fold RANKL expression in osteocyte-like cells and in ex vivo organ bone organ cultures containing authentic osteocytes. Treatment with a neutralizing anti-MIP1? antibody or siRNA-mediated knockdown

of MIP1? in MM cells fully prevented the RANKL upregulation in osteocytes induced by MM cells. Intriguingly, MIP1? also increased osteocyte production of HMGB1, an alarmin cytokine produced by dying cells capable of enhancing RANKL expression. Thus, we next examined the contribution of HMGB1 to osteocytic RANKL regulation by MM cells. Treatment with a neutralizing anti-HMGB1 antibody or genetic inhibition of HMGB1 in osteocytes prevented osteocyte RANKL upregulation by MM cells. Together, our findings suggest that MM-derived MIP1? stimulates HMGB1 in osteocytes, which in an autocrine manner, regulates RANKL expression. These findings unravel a targetable MIP1?-HMGB1 signaling axis regulating RANKL expression in the MM-TME.

Regulation of Osteoblast Nitric Oxide Generation, Glycolysis, and Metabolic Programming by Prostate Cancer *Katrina Clines[1,] Henry Moon[1,] Gregory Clines[1,] [1]University of Michigan, United States

Osteosclerotic bone metastasis is a dynamic and symbiotic relationship between prostate cancer cells and osteoblasts. How osteoblasts respond during the first encounter, when prostate cancer cells arrive in bone, is uncertain. We hypothesized that an initial step is to recruit local and circulating osteoblasts to the metastatic bone niche. To test the hypothesis, GFP-expressing mouse long-bone primary osteoblast cultures were placed on optically opaque 8 μm pore cell culture inserts with one of the human prostate cancer cell lines ARCaPM, ARCaPE, C4-2B, LNCaP, and 22Rv1 cultured below. Osteoblast migration through the membrane was monitored by fluorescence microscopy in hypoxia. ARCaPM and ARCaPE cells markedly increased migration, while the remaining cell lines repelled osteoblast migration. These data suggested that prostate cancers possess different degrees of osteoblast tropism. We next performed single-cell RNA-seq (scRNA-seq) of osteoblast cultures that migrated through the membrane (Migrat OB) and cultures that migrated in the presence of ARCaPM cells plated below (Migrat OB+PrCa), using the 10X Genomics platform. Significant fold increases in osteoblast gene expression were detected in Nos2 (~1200X), Il13ra2 (~900X), Cxcl5 (~70X), Cxcl3, Cxcl1, Rarb, Mmp13, and Bmp7 in the Migrat OB+PrCa compared to the Migrat OB group. Nos2 encodes inducible nitric oxide synthase (iNOS) that generates nitric oxide (NO). Mouse osteoblasts cultured in ARCaPM-conditioned media (CM) increased osteoblast production of NO (24.6 μM) compared to control media (0.5 μM). NO has numerous biologic actions and was recently reported to increase osteoblast anabolism through the regulation of glycolysis. We next determined the transcriptomic differences in osteoblast glycolytic enzymes and found an increase in Pfkfb3, Pfkp, Aldoa, Tpi1, Gapdh, Pgk1, and Ldha in Migrat OB+PrCa vs. Migrat OB groups. Osteoblasts exposed to ARCaPM CM also significantly increased lactate generation, indicating an increase in glycolysis. An increase in the osteoblast energy supply via glycolysis would be critical for promoting the osteosclerotic response, especially in the hypoxic environment of bone metastasis, thus supplying the cells with substrates for collagen and bone matrix synthesis. We report here how prostate cancer changes osteoblast tropism, secretome, and metabolic programming to support prostate cancer and osteoblast growth.

Prostate Cancer Bone Metastasis Alters Gut Microbiota Composition by Enhancing Gut Leakiness *Kelly Contino[1,] Jenna Ollodart[1,] Yang Yu[1,] Sidharth Mishra[2,] Laiton Steele[1,] Katherine Cook[3,] Hariom Yadav[2,] Yusuke Shiozawa[1,] [1]Department of Cancer Biology, Wake Forest University Health Sciences, United States, [2]University of South Florida Morsani College of Medicine, United States, [3]Department of Hypertension, Wake Forest University Health Sciences, United States

In a state of dysbiosis, the physical, biochemical, and immune barriers separtating gut bacteria from systemic circulation become compromised. This loss of gut barrier integrity, referred to as “leaky gut”, has been implicated in the pathogenesis of numerous diseases including cancer. The translocation of the gut derivatives as a result of leaky gut has been shown to drive tumorigenesis and cancer progression, including prostate cancer (PCa). Despite this link to tumor formation/progression, the relationship between leaky gut and metastasis, specifically to the bone, remains unexplored. To begin understanding the complex mechanisms between the gut and bone metastasis, the leading cause of death in PCa patients, we intrafemorally inoculated murine PCa cell line RM-1 cells into C57BL/6 mice. Bulk RNA sequencing of intestinal tissue from these mice revealed that markers of intestinal tight junctions (physical barrier) and gut mucosal membranes (biochemical barrier) were downregulated in the intestinal tissue of PCa-bearing mice. This data suggests that bone metastasis alone is capable of inducing leaky gut. To validate these findings, serum ELISAs for LPS binding protein (LBP) and sCD14, well-established markers of leaky gut, were performed. Significantly higher levels of LBP and sCD14 were observed in the serum of PCa-bearing mice, compared to that of sham mice, further supporting the notion that leaky gut occurs as a result of bone metastasis. Then, to examine whether bone metastasis induces changes in gut microbial composition,16s rRNA sequencing of the mouse stool was conducted. Interestingly, elevated levels of Dorea formicigenerans and Ruminococcus gnavus, mucin degrading bacteria known to enhance leaky gut, were found in the stool of PCa-bearing mice. Several butyrate generating bacteria were found to be upregulated in the stool of PCa-bearing mice. Butyrate is a short chain fatty acid known to contribute to bone formation. Clostridum scindens, known to convert glucocorticoids into androgen, was also elevated in the stool of PCa-bearing mice. Conversely, Faecalibaculum rodentium, known to be protective against intestinal tumor growth, was significantly enhanced in the stool of sham mice. Collectively, these results suggest that bone metastasis alters the gut microbiota composition by enhancing gut leakiness. Future studies are clearly warranted to further reveal the mystery of gut-bone metastasis axis.

Irinotecan’s Effect on Trabecular Long Bone in a Rat Model of Breast Cancer *Bailey Deverell[1,] Kent Algate[1,] Bonnie Williams[1,] Joanne Bowen[1,] Tania Crotti[1,] [1]The University of Adelaide, Australia

Given 90% of people treated for breast cancer with chemotherapy survive five-years post-diagnosis understanding the effects of treatment on bone is essential. Irinotecan, with active metabolite SN-38, is being trialed for breast cancer treatment, yet its effect on bone microarchitecture and turnover is not known. This study aimed to assess irinotecan’s effect on trabecular bone in the femur and tibia of a rat model of breast cancer via micro-CT and histology and on human peripheral blood mononuclear cell (PBMC) viability in culture. Female dark agouti rats were subcutaneously inoculated with breast cancer cells and allocated to vehicle control (n = 8) or irinotecan (175 mg/kg intraperitoneally; n = 8) groups (Ethics: 33965). Rats were euthanised 5 days post-treatment and the femur and tibia were assessed ex vivo via micro-CT for; trabecular thickness (Tb.Th.), trabecular number (Tb.N.), trabecular spacing (Tb.S.), bone volume (BV), and percent bone volume (BV/TV%). Serial sections (5 ?m) of decalcified femur and tibia were stained with tartrate-resistant acid phosphatase (TRAP) and H&E and assessed for multinucleated osteoclast cells on trabecular bone, and adipocytes respectively. TNF? in the rat serum was analysed via ELISA. PBMCs were cultured in vitro with a range of SN-38 concentrations (1 nM - 50 μM) for 48 hours and cell viability assessed via WST-1 assay.Femur and tibia microarchitecture did not significantly differ between groups. Multinucleated TRAP-positive cell number was significantly increased in the tibia of the irinotecan group compared to the vehicle control ($p = 0.033$). Femur and tibia adiposity did not significantly differ between treatment and control groups. TNF? concentration was greater in irinotecan rats (9.145 +/- 1.523) compared to vehicle control (6.300 +/- 1.491), however this was not statistically significant. SN-38 exposure (1 nM - 50 nM) increased cell viability compared to vehicle control in human PBMC culture whilst over 100 nM SN-38 significantly reduced cell viability.Irinotecan increased TRAP+ cells on trabecular bone in the tibia of breast cancer treated rats at five days post treatment. Changes to microarchitecture and adiposity was not evident at this time point. We propose investigating the longer term impacts of irinotecan in the microarchitecture of breast cancer treated rats to align with longer term cancer survivorship.

Using Treadmill Exercise and Vibration to Enhance Drug Delivery to Bone Tumors *Michelle Gelbs[1,] Rodrigo Guerra[1,] Eda Biricik[1,] Dillon Murugesan[1,] Vinagolu Rajasekhar[2,] Darren Veach[2,] Pat Zanzonico[2,] Gene DiResta[3,] John Healey[2,] Susannah Fritton[1,] [1]City College of New York, United States, [2]Memorial Sloan Kettering Cancer Center, United States, [3]Microflow Associates, United States

Metastatic bone cancer is frequently treated using systemic administration of chemotherapeutic agents or bone-sustaining medications such as bisphosphonates. Drug delivery to cancerous tumors is affected by vascularity, rate of diffusion of molecules through the tumor, and heightened interstitial fluid pressure. Loading induced bone deformations increase convective transport via interstitial fluid flow in normal bone tissue. We hypothesize that weight-bearing mechanical loading will enhance drug delivery to bone tumors. In this pre-clinical pilot study, two mechanical interventions were analyzed: treadmill walking and standing on a vibrating platform. To model breast cancer bone metastasis, sixteen 12-13-week-old female nude rats were injected in the right proximal tibia with human breast cancer MDA-MB-231 luciferase-expressing cells (1.25-2.5 million cells in 25 μL of serum-free medium) using an IACUC-approved protocol. IVIS bioluminescent imaging was performed on days 0 and 7 post-injection to assess cell viability. After 8-14 days of tumor growth, three radiolabeled tracers/drugs were used to measure the effects of 10-minute mechanical loading protocols on tumor-uptake: 18F-NaF, 89Zr-trastuzumab, and 89Zr-paclitaxel (n=3-5 per group). The tracers were injected via tail vein in awake rats, mimicking clinical drug delivery. In vivo micro-PET/CT imaging was used to assess tracer uptake in the tumor region before and after walking on a treadmill for 10 min at a speed of 5-12 m/min or standing on a vibrating platform (35Hz, 0.3g peak) for 10 min. After sacrifice, right and left tibiae were scanned using high-resolution micro-CT (Skyscan) and then plastic-embedded for histological assessment. The maximum percent of tracer injected dose per unit volume (%ID/mL) was calculated from right (cancer cell-injected) and contralateral left tibial metaphysis volumes of interest. 18F-NaF had the highest %ID/mL within tumor regions, and 18F-NaF uptake was significantly higher in the right, tumor-bearing tibia after treadmill exercise (Fig. 1). Vibration showed an increasing %ID/mL trend in the tumor-bearing tibia. This pilot study demonstrates that exercise and vibration have potential to amplify drug delivery to tumor regions. Utilizing mechanical interventions on tumor bearing limbs represents a potential

clinical intervention that may enhance a drug's uptake and therapeutic effect while potentially decreasing systemic drug dosage and unwanted side effects.

Bone-derived Dickkopf-Related Protein 1 promotes primary breast cancer tumor growth and supports hematopoietic stem and progenitor cells *Emily Eul[1], Biancamaria Ricci[1], Seunghyun Lee[1], Giulia Furesi[1], Roberta Faccio[1]. [1]Washington University in St. Louis , United States

Dickkopf-related protein 1 (Dkk1), a Wnt/?-catenin signaling inhibitor, is produced in the bone, and is best known for suppressing bone formation and increasing bone resorption. Interestingly, Dkk1 is upregulated in cancer patients and correlates with poor prognosis. Recent work has shown that Dkk1 can exert immune suppressive effects by altering the frequency and function of immune cell subsets in various cancer models. However, the role of Dkk1 in breast cancer progression and the mechanisms by which Dkk1 can affect so many immune cell types remain unclear.We found that mice bearing luminal B, ER+ PyMT-B6 tumors exhibit increased Dkk1 expression in the bone and higher systemic serum levels compared to no tumor bearing controls. To assess the role of Dkk1 during breast cancer tumor progression, female C57BL/6 mice were orthotopically injected with PyMT-B6 cells and treated with Dkk1 neutralizing antibody (?Dkk1) or IgG control antibody (10mg/kg every 48 hrs). We observe a striking reduction in tumor growth of ?Dkk1 treated mice, and systemic alterations to immune cell population frequencies. We also find similar results in mice bearing the metastatic basal-like ER- EO771-LMB breast tumors. To study the effects of bone-dervied Dkk1 we utilized osteoblast lineage specific Dkk1 overexpressing mice (2.3kbCol1?1Dkk1Tg) injected with PyMT-B6 cells and observed increases in tumor growth and changes in the immune landscape.To uncover how Dkk1 can modulate a variety of immune cell populations, we investigated the impact of tumor progression and Dkk1 on hematopoietic stem and progenitor cells (HSPCs) in the bone marrow of tumor bearing mice. Based on previous reports indicating that Dkk1 can influence HSPC regeneration and exhaustion, we performed noncompetitive bone marrow transplantation (BMT) assays using Dkk1 overexpressing mice and osteolineage conditional ckO mice, tTA-TetOFFOsx-Cre; Dkk1fl/fl and saw an increase in the engraftment of HSPC populations from over expressing mice. Additionally, we treated mice with PyMT-B6 or EO771-LMB with ?Dkk1 or IgG and discovered that Dkk1 strickingly reduced HSPC frequencies only in the EO771-LMB model, suggesting that Dkk1 may regulate hematopoiesis in a breast cancer subtype dependant manner.Together this data demonstrates that Dkk1 expression is upregulated in the bones and supports breast cancer tumor growth and hematopoiesis, overall, highlighting the existence of a bone-tumor crosstalk to promote tumor progression.

Assessing Targetability and Optimizing Safety of The Acidic Peptide Conjugates Against Bone Cancers *Losha Jung[1], Philip Low[1]. [1]Purdue University, United States

Bone metastasis is very common in breast and prostate cancer patients, but despite the high incidence, five-year survival rates for both are only 20 to 30 percent. Therefore, there is an urgent need to develop a novel therapy to improve the poor prognosis.Many literatures have reported that negatively charged acidic peptides can recognize positively charged calcium heads of hydroxyapatites exposed in damaged bones and thus have utilized these peptides to deliver small molecules. Previously we have confirmed acidic peptide's ability to concentrate fluorescent or radio-imaging agents selectively to prostate and breast cancer-induced bone lesions. Here we have further assessed and optimized the targetability and safety profile of our acidic peptide to determine its usage as a therapeutic agent against bone cancers.First, we performed a biodistribution study by injecting 177Lu-bound chelator-acidic peptide conjugate into tibial tumor-bearing mice and quantifying radioactivity of each organ at different timepoints. Heart, lung, liver, spleen, muscle, blood, and bone marrow all had low radiation exposure (less than 0.2% average injected dose/g). Kidney uptake was initially high (13.2% avg ID/g), but most were excreted by 72 hours (1.28% avg ID/g). Maximum tumor-bearing bone uptake was observed at 1 hour (1.57% avg ID/g), and similar amount was detected 7 days post-injection (1.55% avg ID/g). To further improve the tumor-to-kidney ratio, we then modified our acidic peptide conjugate by incorporating a renal peptidase cleavable sequence as a linker. From left to right, Figure shows kidneys and tumor bearing bones harvested 24 and 48 hours after an injection of the acidic peptide-fluorescent dye conjugate without and with the linker, respectively. Similar fluorescence intensities were measured at the diseased tibias in both groups of mice at all time points, suggesting that the linker does not impair bone lesion uptake or retention. Furthermore, the incorporation of the linker resulted in 1.5 and 3 times lesser kidney uptake at 24 and 48 hour timepoints, respectively. No other offsite localization was observed. Ultimately, the overall tumor-to-kidney ratio has significantly improved. Rapid renal clearance, specific tumor-induced bone lesion uptake, and prolonged bone retention all collectively support that our compound has potential to be a safe and effective vessel to deliver therapeutic warheads to bone cancers.

PTHrP intracrine signaling domains oppositely regulate primary breast cancer progression through tumor suppressors LIFR and p27 *JEREMY KANE[1], Courtney Edwards[2], Michael Phan[3], Carolina Vogel[4], Jonathan Lowery[4], Rachelle Johnson[5]. [1], United States. [2]Vanderbilt University , . [3]Vanderbilt University, United States. [4]Marian University, United States. [5]Vanderbilt University Medical Center, United States

Parathyroid Hormone Related Protein (PTHrP) is produced by bone and breast cancer cells to regulate bone homeostasis and mammary development. These actions are elicited through its biological domains which mediate receptor binding and cellular localization and are prone to proteolytic cleavage. In metastatic breast cancer, PTHrP paracrine signaling through the PTH receptor (PTHR1) in osteoblasts promotes tumor induced osteolysis, but breast cancer cells exclusively rely on PTHrP actions inside the cell (i.e., intracrine signaling) to alter tumor suppressor genes. However, the role for PTHrP in breast cancer remains unclear, since clinical and pre-clinical studies have identified both pro-tumorigenic and tumor-suppressive roles for PTHrP. We therefore hypothesized that the PTHrP biological domains have opposing functions in breast cancer progression. To test this, we generated MCF7 cell lines that overexpress full-length PTHrP or truncated forms of PTHrP that lack the nuclear localization sequence (NLS) or the NLS and C-terminus. Following inoculation into the mammary fat pad of 6-week old female athymic nude mice (n=7-10), tumor cells expressing PTHrP that lacks the NLS grew faster and formed larger tumors (>3-fold, $p<0.05$), while tumor cells expressing PTHrP that lacks the NLS and C-terminal region grew slower and formed smaller tumors (65% decrease, $p<0.05$) compared to control MCF7 cells, suggesting the PTHrP NLS functions as a tumor suppressor, while the C-terminus is oncogenic. Immunofluorescence of PTHrP mutant cells revealed that deletion of the PTHrP NLS did not preclude PTHrP from nuclear entry, suggesting that truncated PTHrP peptides that lack the NLS may still enter the nucleus to regulate tumor suppressor genes in breast cancer. Indeed, in vivo staining of DNLS tumors confirmed downregulation of LIFR and p27 (87% decrease, $p=0.0008$). We next conducted in silico analyses to determine which regions contribute to nuclear PTHrP intracrine signaling. DP-bind predicted high DNA binding affinity (9/12 residues) in a "gap" region between the PTHrP NLS and C-terminus enriched with lysine and arginine, which AlphaFold predicted as an ?-helix structure when the NLS is removed. This suggests the gap region facilitates DNA binding in the absence of the PTHrP NLS. These results indicate that individual biological domains of PTHrP may take on novel functions in breast cancer that differentially modulate tumor suppressors, contributing to tumor progression.

SUN-114

Breast cancer bone metastasis is mediated by the PTHrP NLS and C-terminal domain in a TGF-?/SNAI2/ZEB1 cascade *DEJA GRANT[1], Julia Ahn[2], Courtney Edwards[3], Jasmine Johnson[4], T. John Martin[5], Rachelle Johnson[4]. [1], United States. [2]Vanderbilt University, United States. [3]Vanderbilt University , . [4]Vanderbilt University Medical Center, United States. [5]St. Vincent s Institute of Medical Research, Australia

Breast cancer cells frequently metastasize to bone, where they may proliferate or enter a dormant state. Parathyroid hormone-related protein (PTHrP) expressed by breast cancer cells promotes tumor outgrowth in bone by increasing bone resorption and stimulating tumor cell exit from dormancy. PTHrP has multiple biological domains that determine its autocrine, paracrine, and intracrine functions, but the role of the PTHrP nuclear localization signal (NLS) and C-terminus is not well understood. To assess the role of PTHrP biological domains in breast cancer bone colonization, we stably expressed full-length secreted PTHrP, PTHrP with deletion of the NLS, or PTHrP with deletion of the NLS and C-terminus in human MCF7 breast cancer cells, which normally lay dormant in bone. MCF7 cells expressing these proteins were termed FLSEC, DNLS, and DNLS+CTERM mutant cell lines, respectively, and inoculated into athymic nude mice by intracardiac injection to facilitate bone colonization (n=8-10/group). Osteolytic lesion area and number, assessed by radiography, and tumor burden in the bone marrow quantified by flow cytometry, were significantly higher in mice inoculated with DNLS (5.9-fold, $p<0.05$) and DNLS+CTERM (4.19-fold, p77% decrease, $p<0.0023$), while ZEB1 was significantly upregulated in DNLS+CTERM cells (2.19-fold, $p<0.05$), compared to MSCV controls. Crosstalk within the TGF-?/Slug/ZEB-1 pathway is exceedingly complex, with bi-directional regulation, depending on the cell type and context. It is also well established that TGF-? positively regulates PTHrP; however, our data suggest that downregulation of Slug may be important for breast tumor progression in bone downstream of PTHrP, and this pathway may or may not converge on ZEB1. Taken together, our data indicate that PTHrP-mediated breast cancer-induced osteolysis involves the NLS and C-terminal domains signaling through EMT-associated pathways.

Multiple myeloma (MM) is an incurable clonal plasma cell (PC) cancer that progresses from monoclonal gammopathy of undetermined significance (MGUS). As the premalignant MGUS PCs share many genomic events and chromosomal aberrations with MM cells, the mechanisms of tumorigenesis remain unclear. Recent evidence suggest that cellular senescence in pretumor PCs and/or their bone marrow microenvironment (BMME) may play a role in MM development. Here, we investigate the burden of senescent PC/MM and their BMME in bone biopsies from patients with stable MGUS (no progression > 10 years; n=20), progressing MGUS (progression < 10 years; n=30) and newly diagnosed MM (NDMM). Sections were immunostained for PC marker CD138 and senescent markers LaminB1 and high motility box group-1 (HMGB1), and digitally analyzed with the HALO imaging software. Cells were classified as “senescent” if they displayed double negative staining for LaminB1 and HMGB1 and as “non-senescent” if they were double positive. Biopsies from progressing MGUS and NDMM patients displayed a significantly higher tumor burden than stable MGUS. Moreover, the non-senescent MM cell density was higher in NDMM than in stable MGUS, reflective of the proliferative disease stage. Stable MGUS biopsies showed a significant increase in senescent PCs per total CD138+ cells than progressing MGUS, revealing the accumulation of non-replicative MM precursors in stable premalignant stages. Interestingly, tumor burden was inversely correlated with accumulation of senescent BMME in stable MGUS patients, suggesting a microenvironmental role in tumorigenesis suppression. Next, we characterized the spatial cellular organization within 25-µm radius of senescent and non-senescent CD138+ PC/MM cells. In biopsies from NDMM patients, but not MGUS, we observed increased CD138+ MM cells neighboring senescent CD138+ cells compared to non-senescent CD138+ cells. As the BMME composition was unaffected, the clonal clustering around senescent PC/MM cells seems to be a cell type-specific feature of overt MM. Furthermore, in all disease stages the majority of senescent CD138+ cells cluster around non-senescent PC/MM, while a higher percentage of senescent BMME cells neighbor the senescent CD138+ cells. Overall, our data suggest that PCs may escape senescence and become replicative during MM tumorigenesis. Further studies aim to elucidate the impact of BMME senescence on MM development, which could be extrapolated to other cancer types.

Detecting Novel Subtypes of Osteosarcoma Using Bayesian Unsupervised Clustering *Sergio Llaneza-Lago[1], WILLIAM FRASER[2], Darrell Green[1]. [1]University of East Anglia, United Kingdom. [2]UNIVERSITY OF EAST ANGLIA, United Kingdom

Osteosarcoma (OS) is a rare and aggressive bone cancer that primarily affects children and young adults. OS has a poor prognosis due to the difficulty in eliminating all tumour cells using currently available treatments, leading to relapse and metastasis. Accurate classification of osteosarcoma into subtypes is essential to optimize treatment pathways and develop targeted drugs. The heterogeneity of OS patients poses a significant challenge to traditional classification methods. One better-suited approach is the Bayesian soft clustering method termed latent process decomposition (LPD). LPD has recently identified a clinically useful aggressive subtype of prostate cancer.The objective of this study is to apply LPD to RNA-seq data from OS patients to detect novel stratifications and characterise them by studying differentially expressed genes and clinical associations.Total RNA expression data plus clinical information of OS patients were downloaded from five publicly available cohorts in the GEO database. Non-biotechnical batch effect was corrected with the R package ComBat. Cohorts were merged and LPD was performed to detect stratifications. OS patients were distributed into groups according to their most representative stratification. Differential expression (DE) analysis was performed using the R package DESeq2 to characterise the identified stratifications. KEGG pathway and GO enrichment analyses were conducted using the R package ClusterProfiler on DE genes. Clinical associations were analysed by assessing relationships between the stratifications and age, gender, survival time, survival status and metastatic occurrence.LPD detected five distinct OS subtypes to which DE genes were identified. These were characterised as a typical cancer-progression subtype, a primary cilium promoter subtype, an indolent subtype associated with muscle development, a bone mineralisation-enriched subtype and a low-prognosis subtype with downregulation of muscle development. Our data highlight the importance of LPD for the in-depth examination of OS subtypes. Further validation and study of these subtypes in other sample cohorts is still required.This preliminary data provides comprehensive insights into the complex genomic processes occurring in OS and a better understanding of its subtypes. This approach will contribute to improving patient care and trial outcomes through better prognosis stratification and facilitate the development of new treatment strategies.

Investigating the Role of Gli2-mediated Transcription in Paclitaxel-Resistant Bone-Metastatic Breast Cancer *JADE MILLER[1], Julie Rhoades (Sterling)[2, 1], . [2]Vanderbilt University Medical Center, United States

Bone-metastatic breast cancer dysregulates bone homeostasis in part through the secretion of parathyroid hormone-related protein (PTHrP) in a process known as the ‘Vicious Cycle’ of tumor-induced bone disease. The transcription factor Gli2 (Glioma-associated oncogene 2) is a well-established mediator of PTHrP expression and is significantly overexpressed by bone-metastatic tumors in comparison to the primary site through alternative TGF-? signaling in the bone microenvironment.Emerging literature has suggested that Gli2-mediated transcription may also drive multidrug resistance (MDR). MDR most often occurs through overexpression of transmembrane drug efflux transporters, which prevent

chemotherapies from reaching therapeutic concentrations within malignant cells. Gli2 has been implicated as a transcriptional regulator of drug efflux transporters such as p-Glycoprotein (P-gp), breast cancer resistance protein (BCRP), and multidrug resistance protein 1 (MRP1) in various cancers including ovarian, prostate, gastric, and melanoma. Thus, we hypothesized that Gli2 activation also confers a chemoresistant phenotype in bone-metastatic breast cancer through transcriptional upregulation of drug efflux transporters.In our studies, we observed tolerance to paclitaxel (PTX) in bone metastatic clones of MDA-MB-231 and 4T1 cell lines in comparison to parental cell lines. We will use genetic knockdown to inhibit Gli2 and re-sensitize bone-metastatic clones to PTX through reduced expression of drug transporters. Conversely, we will overexpress Gli2 in parental (and PTX sensitive) cell lines to confer a PTX-resistant phenotype. Using these modified cells, we will measure changes in gene and protein expression of the drug transporters to establish the mechanisms of Gli2 modulation of MDR genes in bone metastatic breast cancer.Understanding this mechanism will establish an alternative target for modulating MDR genes. This would be an important step, since decades of clinical trials using efflux transporter-targeted therapeutics have failed due to negative patient outcomes caused by the nearly ubiquitous expression of membrane transporter proteins. Thus, identifying Gli2 as a potential therapeutic target for MDR in bone-metastatic breast cancer could lead to a more effective and less toxic therapy.

Targeting S1PR1 and p62-mediated signaling as a therapeutic approach to multiple myeloma bone disease *Daniela N. Petrusca[1], Silvia Marino[2], Attaya Suvannasankha[1], Judith Anderson[1], Evgeny Berdyshev[3], Kelvin P. Lee[1], G. David Roodman[1], Deborah L. Galson[4]. [1]Department of Medicine, Hematology/Oncology Division, Indiana University School of Medicine, United States. [2]Department of Physiology and Cell Biology, University of Arkansas for Medical Sciences, United States. [3]Department of Medicine, National Jewish Health, United States. [4]Department of Medicine, Division of Hematology/Oncology, UPMC Hillman Cancer Center, McGowan Institute for Regenerative Medicine, University of Pittsburgh, United States

Multiple myeloma (MM) is an incurable plasma cell malignancy that causes osteolytic bone lesions in most patients. Thus, novel treatments which effectively target both the MM cells and the bone microenvironment are needed. We previously reported that MM-induced upregulation of GFI1 in bone marrow stromal cells (BMSC) causes prolonged suppression of osteoblast (OB) differentiation. In addition, we described the pivotal role of GFI1 in MM proliferation via intracellular S1P-dependent increased c-Myc stability and enhanced extracellular release of S1P for a pro-survival autocrine and paracrine feedback loop through S1PR1. We employed XRK3F2, a p62-ZZ domain competitive inhibitor that can decrease GFI1 expression in both MM cells and in MM-educated BMSC in vitro, in combination with Ozanimod (Oza), a selective S1PR1 functional antagonist. We found S1P levels significantly elevated in the BM plasma of MM patients when compared to healthy donors. Also, S1PR1 and p62 are highly expressed in MM primary cells when compared with healthy donors and negatively correlate with overall survival of MM patients. Microenvironmental soluble factors (IL6, S1P, TNF?, hypoxia) and the direct co-culture of MM cells with BMSC cells, significantly increase S1PR1 transcription as well as GFI1 (mRNA and protein expression) levels in both cell types. We found that XRK3F2 significantly downregulated both p62 and GFI1 levels in MM cells even in the presence of IL-6, and Oza significantly decreased S1PR1 levels even in the MM cells overexpressing GFI1. Each drug alone significantly reduced viability in MM cells and their combination further enhanced the pro-death effect. Either drug alone significantly decreased GFI1 and P-cMyc protein levels in MM cells as well as c-Myc chromatin bound levels. These effects were further accentuated by the drugs in combination. We found that XRK3F2 and OZA, alone and in combination, improve differentiation of pre-OB. Moreover, either drug alone significantly rescued TNF? suppression of OB differentiation, and their combination completely restored it as measured by Col1a1 levels. Oza treatment of MM downregulated IL6 and RANKL levels even in MM cells overexpressing GFI1. IL6 and RANKL increase MM viability and osteoclast recruitment and activation, respectively. These data support the idea that p62 and S1PR1 might be effective targets in MM treatment and the potential of using the Oza-XRK3F2 combination as a novel therapeutic approach for treating MMBD.

Myeloid Hif1? stimulates the formation of osteoblastic lesions when apoptosis is induced in a model of prostate cancer bone metastasis. *Hernan Roca[3], Maria Molina Sanchez[3], VERONICA MENDOZA REINOSO[2], LENA BATOON[3], Gustavo V. de Oliveira Fernandes[3], Carlos Pirela[3], AMY KOH[4], John Rubin[3], Laurie McCauley[5]. [3]University of Michigan, United States. [2], United States. [3]University of Michigan, . [4]U OF MICHIGAN, United States. [5]University of Michigan School of Dentistry, United States

Prostate cancer (PCa) preferentially metastasizes to bone, a site rich in myeloid cells and where interaction between cancer and bone cells leads to bone remodeling dysregulation. The result is mixed pathological bone destruction and formation. In human PCa, the formation of osteoblastic bone lesions predominates, resulting in bone pain and is associated with poor prognosis. Cancer growth in bone promotes a hypoxic environment with increased frequency of apoptosis. The clearance of dying cells (efferocytosis) in bone is performed by professional phagocytes, mainly macrophages (M?s). Hypoxia activates the transcription factor Hif1?, which in M?s, even under normal oxygen concentrations, becomes stabilized and activated by efferocytosis of cancer cells. Here we used PCa cells with inducible Caspase-9 mediated apoptosis in a syngeneic mouse model of bone tumor growth to analyze the effect of myeloid Hif1? inactivation when apoptosis is induced in skeletal tumors. LysM-Cre+/- mice were crossed with Hif1?-floxed mice to obtain the Hif1? mutant in myeloid lineage (Hif1?mut), rendering Hif1? inactive in these cells. PCa cells were inoculated via intratibial injection in wild-type (WT (Hif1?flox)) or Hif1?mut mice. Apoptosis was induced at d3 and d5 post-cancer inoculation via intraperitoneal injection of the dimerizer AP20187. Tibiae were collected at d6. Medullary bone volume was significantly higher in tumor-injected tibiae relative to non-injected contralateral bone, demonstrating the predominance of osteoblastic lesions ($p<0.0001$). Histological H&E showed no significant differences in tumor area relative to the total bone marrow area when comparing WT vs. Hif1?mut groups. However, μCT analyses demonstrated a reduced medullary bone volume ($p<0.01$) and fractional bone volume (BV/TV, $p<0.05$) in Hif1?mut vs. WT tibiae-bearing tumors. The analysis of trabecular thickness mimicked the differences in BV/TV ($p<0.05$), while no difference was found in trabecular number between the groups. Immunofluorescence revealed reduced F4/80+ M?s in the tumors ($p<0.05$) of Hif1?mut vs. WT, but no differences in cells lining newly formed bone surfaces within the tumors (F4/80+, CD68+ (phagocytic), TRAP+ (osteoclasts) or OSX+ cells). Altogether, these findings uncover a previously unknown role of myeloid Hif1? in the development of tumor-mediated osteoblastic lesions where cancer cell apoptosis likely accelerates macrophage infiltration/differentiation to promote bone formation.

Adult T cell Leukemia (ATL), caused by chronic infection of human CD4+ T cells with HTLV-1, is associated with hypercalcemia and osteolytic lesions. To study the direct effect of HTLV-1-infected T cells (HTLV/T) on osteoclasts (OC), we generated a panel of clonal HTLV/T (n=9 from 2 donors) and ATL patient cell lines (ATL/P) (n=3). Supernatants (sup) from HTLV/T and ATL/P were added to murine and human OC precursors cultured in suboptimal osteoclastogenic conditions. HTLV/T sup variably stimulated OC differentiation (4 high, 1 medium, 4 low), but showed identical effects on murine and human cultures. ATL/P sup all stimulated OC generation. Expression of RANKL and OPG mRNAs by HTLV/T and ATL/P was variable, but we found no correlation between OC effects and either RANKL levels or RANKL/OPG ratio, suggesting an alternative mechanism. Concordantly, we previously showed that osteolysis in a humanized mouse model of HTLV-1 infection was only partially blocked by anti-RANKL antibodies. HTLV/T and ATL/P produce small extracellular vesicles (sEV), known to facilitate HTLV-1 infection. We hypothesized that these sEV also mediate bone loss by targeting OC. We isolated sEV from both HTLV/T and ATL/P, and found they carried most of the activity of sup. In contrast, sEV from uninfected activated T cells had little effect. Pre-treatment of HTLV/T by exosome inhibitor GW4869 blunted the OC stimulatory activity of sup. We further characterized the sEV, finding no viral particles using transmission EM. LC-MS/MS of HTLV/T sEV (n=7) showed no RANKL, but ~18% of sEV proteins correlated with strength of osteoclastogenic effect; gene ontogeny analysis of this group showed increased representation of proteins involved in bone resorption such as cytoskeletal proteins and GTPases. MicroRNA profiling of HTLV/T sEV with high osteoclastogenic activity revealed top microRNAs (mir 21, mir 155, mir 92a1) with previously noted effects on OC. To determine if in vitro findings correlate with true osteolysis, HTLV/T lines (2 high and one low effect) were injected into tibias of immunodeficient NCG mice, and trabecular bone mass was followed by vivaCT. HTLV/T with high in vitro activity caused profound bone loss by 4-8 weeks regardless of RANKL expression ($p<0.01$), while bone injected with the low effect line was not significantly different from uninjected controls.

Our study suggests that sEV, which lack RANKL, directly stimulate OC, likely mediated by multiple components of their cargo.

PPP1R3C regulates enchondroma formation and mediates cholesterol activity in IDH mutant cartilage tumors *Makoto Nakagawa[1], Nicholas Guardino[1], Eijiro Shimada[1], Vijitha Puviindran[1], Emily Peairs[1], Koji Ishikawa[1], Puviindran Nadesan[1], Banjamin A. Alman[1]. [1]Duke University, United States

Enchondroma (ECA) and chondrosarcoma (CSA) are common cartilage neoplasms that are either benign or malignant, respectively, and frequently associated with mutations in isocitrate dehydrogenase (IDH)1 or IDH2. Although the role of IDH mutations in metabolic reprogramming has been studied, their impact on chondrocytes and CSA is still unclear. Our previous work has shown that IDH mutated chondrocytes and CSA have higher glycogen levels and enhanced glycolysis, suggesting that IDH mutation effectively utilizes glycogen as an energy source. Protein Phosphatase 1 Regulatory Subunit 3 (PPP1R3C), which activates glycogen synthesis, is highly expressed in chondrocytes and CSA expressing a mutant IDH. Here, we investigated the role of PPP1R3C on cartilage differentiation and cell viability in growth plate chondrocytes and CSA, respectively. Deletion of PPP1R3C (Col2a1Cre; Idh1LSL/WT; Ppp1r3cfl/fl) rescued the phenotype of embryos with mutant IDH1 (Col2a1Cre; Idh1LSL/WT) that displays increased Col X-positive length of growth plate chondrocytes at E18.5, a major cause of ECA formation (Figure). Moreover, glycogen levels and cell viability of CSA cells were dramatically increased by PPP1R3C overexpression and significantly decreased by PPP1R3C knockout, respectively. These results indicate that PPP1R3C enhances glycogen synthesis and is responsible for cartilage differentiation and cell viability. We also identified putative binding sites for sterol regulatory element binding protein 2 (SREBP2) on the PPP1R3C promoter sequence. SREBP2 is upregulated by IDH mutation, and the overexpression of SREBP2 in CSA cells increased PPP1R3C expression. Furthermore, ChIP-qPCR revealed that SREBP2 was more strongly recruited to the promoter regions of PPP1R3C under SREBP2 overexpression, indicating that PPP1R3C is directly regulated by SREBP2. Finally, deletion of SCAP (Col2a1Cre; Scapfl/fl), which regulates SREBP2 activity, resulted in disrupted structure in proliferating and hypertrophic chondrocytes at E17.5, whereas overexpression of PPP1R3C (Col2a1Cre; Scapfl/fl; Ppp1r3cOE) partially rescued the phenotype. Taken together, our study sheds light on the mechanisms underlying the role of PPP1R3C in IDH mutated chondrocytes and CSA and highlights PPP1R3C as a potential therapeutic target for the treatment of these neoplasms. We also provide evidence for direct crosstalk between glycogen and cholesterol biosynthesis in growth plate chondrocytes, both upregulated by IDH mutation.

Effect of acridine orange and zoledronic acid on renal cell carcinoma local bone metastasis model *Keita Oya[1], Hiroyuki Tsuchie[1], Hiroyuki Nagasawa[1], Michio Hongo[1], Yuji Kasukawa[1], Daisuke Kudo[1], Ryo Shoji[2], Fumihito Kasama[3], Kento Okamoto[1], Tsuyoshi Kawaragi[1], Manabu Watanabe[1], Kenta Tominaga[1], Naohisa Miyakoshi[1]. [3]Department of Orthopedic Surgery, Yuri Kumiai General Hospital, Japan

Purpose:Renal cell carcinoma is one of the carcinomas that can cause bone metastasis, and approximately 30% of patients have bone metastasis at the time of diagnosis. Therefore, renal cell carcinoma is relatively prone to clinical problems due to skeletal related events. Acridine orange (AO) is an acoustic-, light-, and radiation-sensitive substance with a specific affinity for cancer cells and is known to promote apoptosis of cancer cells upon external stimulation. We previously demonstrated that AO inhibited cancer cell growth and zoledronic acid (ZA) prevented bone destruction in a mouse model of breast cancer bone metastasis. This study aimed to investigate the effects of ZA and AO using a mouse model of local bone metastasis of renal cell cancer.Method:Renca, a cell line of renal cell carcinoma derived from BALB/c mice was suspended in 10 ?l of phosphate-buffered saline and injected into the femur of 6-week-old BALB/c mice. ZA was injected subcutaneously every week, starting at 2 weeks after injection of Renca, when the tumor cells in the bone had grown sufficiently. Similarly, AO was injected into the tail vein 2 weeks after the injection of Renca and irradiated with 5 Gy of radiation 2 h later. The mice were divided into Control, ZA, AO, and ZA+AO groups (n=20 per group) based on these interventions, and further subdivided into sacrifice groups (n=10 per group) after 3 and 5 weeks of Renca injection. On the day of sacrifice, ?CT was taken to examine the extent of periosteal reaction (abnormal bone formation rate) due to bone metastasis along the total length of the femur.Results:The ZA, AO, and ZA+AO groups had significantly lower abnormal bone formation rates than the Control group at both 3 and 5 weeks after Renca injection ($p<0.05$). However, there were no significant differences with respect to the ZA, AO, and ZA+AO groups.Conclusion:ZA and AO may inhibit the growth of renal cell cancer bone metastases.

[6]Hannover Medical School, Department of Pediatric Hematology and Oncology, Hannover, Germany

Introduction: Vitamin D status is investigated as a modifier for the risk and course of multiple malignant diseases. Findings point towards a detrimental role of low vitamin D levels for event free and overall survival (EFS/OS). A vitamin D deficiency is often associated with low calcium stores, which may lead to secondary hyperparathyroidism. We hypothesized that hyperparathyroidism may influence EFS/OS in childhood malignancies.Methods: Real world data from 1547 cases (873 male) of childhood malignancies (397 lymphatic) from a single center tertiary university hospital were anonymized and analyzed. Laboratory data sets with relevance to calcium homeostasis including plasma parathyroid hormone (PTH) and serum 25-OH-vitamin D (25OHD) from 01/2000 - 7/2021 were obtained and filtered for the highest PTH and lowest 25OHD of each patient during the entire observation period. Data on relapse, secondary malignancies and mortality were obtained via chart review; from the German Childhood Cancer registry (Kinderkrebsregister) and from the ALL-BFM study group. Data were stratified for the presence/non-presence of hyperparathyroidism (PTH > 65 pg/ml) and the presence/non-presence of a vitamin D deficiency (25OHD <30 nmol/L). EFS/OS of the entire cohort and six disease specific groups was analyzed. Results:In lymphatic malignancies hyperparathyroidism was associated with inferior EFS (Hazard Ratio (HR) 2.25 [1.38 - 3.66]), but not with inferior OS (HR 1.85 [0.71 - 4.80]) and deficient vitamin D levels did not associate with inferior EFS/OS.In the entire cohort and for the other diagnostic strata neither hyperparathyroidism nor vitamin deficiency during follow-up was associated with inferior EFS/OS.Conclusion: In childhood lymphatic malignancies, hyperparathyroidism at any time during follow-up is associated with inferior EFS and may mediate the discussed effects of low vitamin D. Further prospective and mechanistic studies on this subject are urgently needed.

Osteocytes Induce Drug Resistance via the NOTCH3-CXCL12 Signaling Axis in Multiple Myeloma *Hayley Sabol[1,] Cody Ashby[1,] Manish Adhikari[1,] Japneet Kaur[1,] Aric Anloague[1,] Sharmin Khan[1,] Samrat Roy Chodhury[1,] Michela Palmieri[1,] Lawry Barnes[1,] Elena Ambrogini[1,] Carolina Schinke[1,] Intawat Nookaew[1,] Jesus Delgado-Calle[1,] [1]University of Arkansas for Medical Sciences, United States

Multiple myeloma (MM) remains incurable due to disease relapse and drug resistance. Notch signals between MM cells and cells of the tumor niche (TME) confer drug resistance, but the cellular/molecular mechanisms are not entirely known. Using in silico analysis of clinical and transcriptomic public and internal databases, we found that 1) NOTCH3 is up-regulated in MM cells from newly diagnosed MM patients (NDMM) vs. healthy donors, 2) increases in relapsed/refractory MM (RRMM) vs. NDMM patients, and 3) NDMM patients with high NOTCH3 expression have worse responses to Bortezomib (BOR)-based therapies. Because NOTCH3 mRNA levels did not correlate with somatic mutations in NOTCH3, we tested if NOTCH3 is regulated by TME cells and its role in responses to chemotherapy. Osteocytes (Ots), recently defined as key cells in the TME, increased NOTCH3 in MM cells and protected them from apoptosis induced by BOR or VRd (BOR+Lenalidomide+Dexamethasone) in vitro. This protection was lost by NOTCH3 knockdown (NOTCH3KD) and enhanced by NOTCH3 activation (NOTCH3OE) in MM cells. Next, we compared BOR (0.1 mg/kg, 5x/wk) responses in control (C) vs NOTCH3OE MM cells in vivo. All untreated mice bearing C or NOTCH3OE cells died at 4 wks. In mice injected with C MM cells, BOR reduced tumors by 65%, improved survival (7/10 alive), and had 38% more bone mass, 25% more P1NP, and 29% less CTX than untreated mice. In contrast, in NOTCH3OE-bearing mice, BOR only reduced tumors by 23% and did not improve survival (1/10 alive), bone mass, or serum markers, supporting NOTCH3 confers BOR resistance. We then compared the MM cell transcriptome of NDMM patients with high vs. low NOTCH3 expression to find the mechanism for BOR resistance. We found that high NOTCH3 NDMM and RRMM patients had enrichment in chemokine and cell adhesion pathways and CXCL12 upregulation. Ots upregulated CXCL12 and activated the CXCR4/ERK pathway in MM cells in vitro. These effects were blunted in NOTCH3KD and enhanced in NOTCH3OE MM cells. Genetic inhibition of CXCL12 in NOTCH3OE cells prevented Ot's protection and restored BOR/VRd sensitivity, supporting CXCL12 works in an autocrine fashion. Lastly, Plerixafor, a CXCR4/CXCL12 inhibitor, restored NOTCH3OE MM cells sensitivity to BOR/VRd in vitro and in human bones bearing NOTCH3OE tumors cultured ex vivo. Our clinical and experimental data show Ots transmit drug resistance signals and unravel a novel targetable NOTCH3-CXCL12 pro-survival signaling axis in the MM TME.

N-cadherin in Osteolineage Cells Restrains a Tgf-?1-driven Vicious Cycle to Reduce Tumor Growth *Toshifumi Sugatani[1,] Roberto Civitelli[1,] [1]Washington University in St. Louis School of Medicine, United States

Tumor growth and metastases are dependent on interactions between the tumor cells and tumor microenvironment (TME) cells. Expression of N-cadherin (Ncad), a calcium-dependent cell-cell adhesion molecule, in transformed cells is the hallmark of epithelial-to-mesenchymal transition, which favors tumor growth and metastasis. While research has focused on Ncad in tumor cells, lesser attention has been given to how Ncad in TME cells may contribute to the interaction between the tumor and the tissue in which it grows. It has been reported that Ncad in cancer associated fibroblasts is pro-tumorigenic. However, we found that Ncad in osteogenic cells present in the TME of breast cancer is anti-tumorigenic. In previous unpublished studies we also found that Tgf-?1, a well-established pro-tumorigenic factor, is upregulated in Cdh2 KO MC3T3-E1 cells (Cdh2KO OB), generated by CRISPR-Cas9 gene editing. Specifically, we found that under Tgf-?1 stimulation, PI3K/Akt/?-catenin signaling and Sp1 and Lef1 mRNA expression are elevated in Cdh2KO OB cells. In turn, binding activity of Sp1 and Lef1 transcription factors to the Tgf-?1 promoter is increased in Cdh2KO OB cells relative to wild type (WT) OB cells. To validate the biologic relevance of these in vitro findings, we generated Tgfbr1 (Tgf-? receptor 1) KO (Tgfbr1KO) tumor cells, also using CRISPR-Cas9, and co-injected them with either Cdh2KO or WT OB cells into the mammary fat pads of C57BL/6J female mice. Injections of WT or Tgfbr1KO tumor cells were also performed as control. After 7, 9, 11, 13, and 15 days inoculation, tumors were measured in size, and after 15 days inoculation, tumors were removed and weighed. Co-injection of WT OB cells greatly enhanced tumor growth, and the effect was enhanced by co-injection of NcadKO OB cells by day 15, corroborating the notion that Ncad in OB cells is anti-tumorigenic. In addition, either WT or Chd2KO OB cells failed to induce tumor growth when co-injected with Tgfbr1KO tumor cell, indicating that Tgf-?1 drives a pro-tumorigenic, feed-forward mechanism via osteogenic cells in vivo. Thus, we propose that Ncad in TME cells with osteogenic signature restrains breast tumor growth by exerting a "breaking" effect on a Tgf-?1-driven vicious cycle.

How the administration timing of zoledronic acid affects metastatic bone tumors *manabu watanabe[1,] hiroyuki tuchie[1,] hiroyuki nagasawa[1,] michio hongo[1,] yuji kasukawa[1,] daisuke kudo[1,] fumihito kasama[1,] Keita Oya[1,] takashi kawaragi[1,] Naohisa Miyakoshi[1,] [1]Akita University Graduate School of Medicine, Japan

Introduction:Breast cancer is one of the most common cancers in women; and it presents with various symptoms. In particular, those associated with bone metastasis are known to cause severe pain, and are often accompanied by fractures, which impact negatively on daily life. Bisphosphonate preparations, known as therapeutic agents for osteoporosis, are also used to treat bone metastasis. Zoledronic acid (ZA) is understood to suppress the progression of bone metastases and to relieve pain; however, it is uncertain as to whether the timing of the administration is associated with differences in outcomes. In this study, we administered ZA to breast cancer model mice with bone metastasis, at different points in time, to examine whether the timing of the administration caused differences in the effect. Method:E0771 cells were adjusted to a concentration of 1.0×105/10 µl with PBS and injected into the femurs of C57BL/6N mice. Given that tumor cells in the bone proliferate sufficiently two weeks after tumor administration, 100 ?g/kg of ZA was administered one week before tumor administration, at the same time as tumor administration, and one week after tumor administration. In addition, a group which did not receive ZA was included. Two weeks after tumor administration, the mice were sacrificed and evaluated. Body weight and tumor volume, before tumor administration and at the time of sacrifice, were compared between the groups.Results:Engraftment of tumor tissue was confirmed in all the femurs. There was no significant difference in body weight between the groups at the time of the tumor administration and at the time of sacrifice. In addition, there was no significant difference in tumor volume between the groups.Conclusion:Based on the finding at the time of sacrifice, which was two weeks after tumor administration, the timing of the administration of ZA did not affect the anti-tumor effect of the drug. Moving forward, we believe that it is necessary to confirm the differences in the long- term course and to further evaluate the consequent bone tissue.

Microtubule Dynamics in Bone Metastasis of Breast Cancer *Shreya Patel[1,] Marcus Winogradzki[1,] Jitesh Pratap[1,] Waddell Holmes[1,] Ahmad Othman[2,] Alan Blank[1,] Niyati Patel[1,] Ryan Ross[1,] [1]Rush University Medical Center, United States, [2]Northwestern University, United States

Bone metastasis (BM) remains a major cause of morbidity in advanced cancer patients. Median survival rates of the two most common BM cancers, breast and prostate, range from 19-25 months and 12-53 months, respectively. Treatment strategies usually rely on surgical resection of tumors, combined with radio- and/or chemotherapies like paclitaxel, which target microtubules (MT). The efficacy of these approaches is diminished by tumor recurrence and drug resistance. Growing evidence points to dysregulated expression of tubulin isotypes as a major driver of chemoresistance. MTs are composed of heterodimers of ?- and ?-tubulins. Tubulin ?3 has been most studied for its resistance to taxanes and vinca alkaloids, with high expression correlating to poor patient outcomes. Tubulin isotypes are distinguished by their c-terminal domain and a variety of post-translational modifications (e.g., acetylation) that facilitate specific protein interaction. Currently, little is known about how microtubules change during bone metastasis. Here, we set out to profile these changes by assessing differences using RNA-Seq data, mass spectrometry, xenograft models, and breast cancer patient samples. RNA-Seq analysis between a set of bone metastatic and a set of non-metastatic breast cancer cell lines (n=10) revealed differential expression of tubulin ? isotypes with increased expression for tubulin ?2a, ?2b, and ?6. Protein levels of tubulin ?2 were higher in the aggressive MDA-MB-231 compared to MCF7 breast cancer cells. Immunohistochemis-

try of BM tumors shows increased ?3 and acetylated ?-tubulin (Ac-?-Tub) staining compared to matched primary tumors. Ac-?-Tub promotes microtubule stability and supports vesicular trafficking. Together these findings suggest specific microtubular changes during cancer cell adaptation to the bone. We and others have reported that Runx2 promotes bone metastasis. Inhibiting Runx2 in MDA-MB-231 leads to decreased Ac-?-Tub as well as tubulin ?2. Mass spectrometry and immunoprecipitations suggest that Runx2 regulates the interaction of MT-associated proteins and HDAC6 with ?-tubulin, preventing its deacetylase activity. Loss of Runx2 sensitized these bone metastatic cells to docetaxel and vinblastine treatment, as well as reduced secretion of IL-6. In summary, our results suggest specific changes in microtubule cytoskeleton during BM, as well as novel therapeutic targets that may lead to more effective chemotherapeutics to inhibit tumor growth in bone.

Osteoblasts are a source of bone metastases-associated fibroblasts (BMAFs) *Jennifer Zarrer[1], Marie-Therese Haider[2], Nicole Ridlmaier[2], Rafael Preuer[2], Daniel J. Smit[3], Hiroaki Saito[1], Eric Hesse[1], Hanna Taipaleenmäki[1]. [1]Institute of Musculoskeletal Medicine, University Hospital, LMU Munich, Munich, Germany, Germany. [2]Molecular Skeletal Biology Laboratory, Department of Trauma, Hand and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, Germany. [3]Institute of Biochemistry and Signal Transduction, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, Germany

In breast cancer bone metastases the abundance of adjacent osteoblasts (OBs) is diminished. To determine the fate of OBs, we combined a lineage-tracing model (Osx-creERt+;Ai9) with intracardiac injection of 4T1 breast cancer cells and performed single cell RNA sequencing (scRNAseq) of tdTomato-positive (tdTom+) OBs in metastases-bearing and healthy control animals. Bioinformatic analysis revealed a distinct cluster of tdTom+ OBs in metastases-bearing mice that express genes related to tumor microenvironment, fibrosis and cancer-associated fibroblast (CAF) proliferation (e.g. Cxcl12, Tnc, Mmps, Pdgfr-?, Pdgfr-?). CAFs reside inside tumors providing a micro-milieu that supports tumor growth. However, little is known about metastasis-associated fibroblasts (MAFs), in particular in bone metastases. Based on our findings, we hypothesized that OBs might abandon the bone surface and become MAFs. Supporting our hypothesis, histological analysis demonstrated elongated tdTom+ OBs within metastases, which we termed bone metastases-associated fibroblasts (BMAFs), while only a few OBs were present on nearby bone surfaces. Consistently, MC3T3-E1- and primary OBs acquired a spindle shape morphology upon stimulation with medium conditioned by 4T1 or MDA-MB-231 breast cancer cells (CCM), which also increased OB migration and OB-induced collagen remodeling. Furthermore, in an ex vivo co-culture model, OBs in the vicinity of cancer cells became elongated and migrated in-between tumor cells. Immunoblot, qRT-PCR, scRNAseq and histological analyses revealed a reduction of OB markers (Runx2, Osx) and an increase of BMAF-associated genes (e.g. Pdgfr-?, Pdgfr-?) in CCM-stimulated OBs and cancer-associated tdTom+ OBs. To elucidate the mechanisms transitioning OBs to BMAFs, we performed RNA sequencing and identified an activated IL-17A signaling pathway in CCM-stimulated OBs compared to controls, which was confirmed by immunoblot and qRT-PCR analyses of downstream targets (C/ebp, Ccl2). Furthermore, recombinant IL-17A promoted OB migration and acquisition of a BMAF phenotype while inhibition of IL-17A signaling using an anti-IL-17 antibody restored the CCM-induced morphological changes and OB migration. In vivo, anti-IL-17A reduced the number and growth of bone metastases determined by bioluminescence imaging and histology. Together, these results demonstrate that OBs give rise to BMAFs at least in part through IL-17A, which might contribute to metastatic growth.

Investigating Novel RNA Transcripts in Primary Bone Cancer-derived Circulating Tumour Cells *Emma Bull[2], Sergio Llaneza-Lago[2], WILLIAM FRASER[3], Darrell Green[2]. [2]University of East Anglia, . [2]University of East Anglia, United Kingdom. [3]UNIVERSITY OF EAST ANGLIA, United Kingdom

Primary bone cancers (PBCs) are a heterogeneous group of cancers. PBCs primarily arise in children and adolescents. The five-year survival rate for localised disease is ~50% but ~20% for metastatic disease. Standard of care and survival rates have not improved since the 1960s. Better understanding of PBC biology leading to more effective and less toxic treatments is urgently required. Metastasis is the leading cause of bone cancer-related death, but metastatic samples are difficult to obtain because surgery is scantly used at late-stage disease. We recently developed protocols to isolate circulating tumour cells (CTCs) from PBC patient blood to investigate the “seeds” of metastasis at single cell resolution. We identified novel RNA transcripts in CTCs that were not observed in normal or tumour tissue. This data suggests that (i) some novel RNAs are unique to metastasis and/or (ii) pro-metastatic cancer cells are capable of producing their own disease-promoting gene networks. This project aims to validate and characterise the mechanism of action of these novel RNAs. Whole blood samples (7.5mL) were obtained from ten patients with osteosarcoma or Ewing sarcoma. The ClearCell FX (Biolidics) was used to isolate live and viable CTCs. Single CTCs were then manually picked from the output using brightfield microscopy and pipetting. The SMART-Seq® mRNA Single Cell LP kit was used to generate libraries for single cell RNA-seq (scRNA-seq). scRNA-seq revealed 347 significantly differentially expressed genes between CTCs and control cell lines. A completely uncharacterised 2498 base pair transcript that we term LNC441 was expressed in CTCs but not observed in controls. Early bioinformatics analysis suggest that this transcript is a long non-coding RNA housing multiple new and unknown microRNA hairpins. Characterising LNC441 will reveal previously unknown networks promoting PBC metastasis. Our study may identify new therapeutic targets for reducing or halting PBC dissemination.

DDRGK1 regulates proteostasis by modulating the ribosomal protein RPL26 during chondrocyte differentiation in spondyloepimetaphyseal dysplasia *Yangjin Bae[2], Monika Weisz-Hubshman[2], Carolina Leynes[2], Sung Yun Jung[2], Brendan Lee[2]. [2]Baylor College of Medicine, United States. [2]Baylor College of Medicine,

DDRGK1 is a substrate of the ufmylation process, a post-translational modification mediated UFM1.It is required for subsequent ufmylation of other substrates by forming complex with ULF1 (E3 ligase). The physiological importance of DDRGK1 was elucidated by the finding of mutations in Shohat-type Spondyloepimetaphyseal dysplasia (SEMD). Moreover, other genes in this pathway have since been associated with this spectrum of skeletal dysplasias. We previously showed that osteochondroprogenitor-specific (Prx1-Cre; Ddrgk1f/f) and mature chondrocyte- specific (Agn1-CreERT2; Ddrgk1f/f) knockout mouse models recapitulated the SEMD phenotype. In brief, Prx1-Cre; Ddrgk1f/f mice showed severe chondrodysplasia including progressive shortening of the limbs with an abnormal growth plate and a delayed epiphyseal ossification. In Agn1-CreERT2; Ddrgk1f/f mice, we consistently found disorganized growth plate and reduced level of proteoglycan in growth plate and articular cartilage. These in vivo results highlight the essential role of UFM1 modification in cartilage development and homeostasis. Hence, to uncover the potential cartilage-specific complexes and novel substrates of the ufmylation, we have generated ATDC5 (murine chondrocyte cell line) stably expressing the components of the ufmylation machinery, i.e., UFC1-FLAG; UFL1-MYC; HA-HIS-UFM1 via doxcyclin induction and performed IP-MS assay. Based on GO analysis, we found proteins enriched in protein ufmylation (as internal control), ER stress, protein translation pathways and ribosome. Among these, ribosomal protein RPL26 was previously reported as the substrate of UFM1 modification and also the cause of with a human ribosomopathy. Similar to the function of Ddrgk1 in proteostasis, we found that total protein synthesis was reduced by SUnSET assay (Surface Sensing of Translation) when Rpl26 was knockdown in ATDC5, with associated impairment of ATDC5 chondrocyte differentiation. We also found that Sox9 protein level was decreased similarly when Ddrgk1 was knockdown in ATDC5. These data suggest that ufmylation may be a critical post-translational modification for cartilage homeostasis by modulating the protein stability/function of subset of ribosomal proteins such as RPL26. Furthermore, this mechanism underscore the evidence of tissue-specific ribosomal function as a pathological cause of human chondrodysplasia.

Loss of function variant in histone reader SPIN4 causes a new X-linked overgrowth syndrome *Julian Lui[1], Jacob Wagner[1], Elaine Zhou[1], Kevin Barnes[1], Lijin Dong[2], Youn Hee Jee[1], Jeffrey Baron[1]. [1]Section on Growth and Development, NICHD, United States. [2]National Eye Institute (NEI), United States

Overgrowth syndromes can be caused by pathogenic genetic variants in epigenetic writers, such as DNA and histone methyltransferases. However, no overgrowth disorder has previously been ascribed to variants in a gene that acts primarily as an epigenetic reader. Here, we studied a male individual with generalized overgrowth of prenatal onset. Exome sequencing identified a hemizygous frameshift variant in Spindlin 4 (SPIN4), with X-linked inheritance. We found evidence that SPIN4 binds specific histone modifications, promotes canonical WNT signaling, and inhibits cell proliferation in vitro and that the identified frameshift variant had lost all of these functions. Ablation of Spin4 in mice recapitulated the human phenotype with generalized overgrowth, including increased longitudinal bone growth. Growth plate analysis revealed increased cell proliferation in the proliferative zone and an increased number of progenitor chondrocytes in the resting zone. We also found evidence that loss of Spin4 in mice led to decreased canonical Wnt signaling in growth plate chondrocytes, potentially contributing to increased pool of progenitor cells in the resting zone.Taken together, our findings provide strong evidence that SPIN4 is an epigenetic reader that negatively regulates mammalian body growth, and that loss of SPIN4 causes an overgrowth syndrome in humans, expanding our knowledge of the epigenetic regulation of human growth.

Piezo1 activation accelerates endochondral osteogenesis-mediated fracture healing and the targeted intervention effect of resveratrol *Donghao Gan[1], Wenjing Zhang[2], Qingyun Jia[3], Guozhi Xiao[1]. [1]Southern University of Science and Technology of China, China. [2]Shenzhen Institute of Advanced Technology, China. [3]Linyi People's Hospital, China

Background Fracture is one of the most common injuries in humans, and despite advances in surgical treatment, approximately 5-10% of patients will progress to delayed union or nonunion. Therefore, it is urgent to explore therpeutic targets for promoting fracture healing and shorten the healing time.Objectives To investigate the effects of Piezo1 activation on bone fracture healing and to explore Piezo1-targeting fracture healing treatment.Methods The expression levels of Piezo1 were determined in human and mice fresh callus tissue. Mice with genetic Piezo1 deletion in chondrocytes or local injection of the Piezo1 activator Yoda1 were utilized to determine the effects on fracture healing. In an effort to define Piezo1-targeting drugs for potential fracture treatment, via virtual docking technology in the constructed compound library, we found that Resveratrol (RSV) may be a PIEZO1-targeting drug. Then, we developed an injectable RSV loaded hydrogel platform as a high payload and sustainable release for fracture treatment.Results Piezo1 expression was elevated in callus tissue chondrocytes in human and bone fracture mouse model. Piezo1 deletion in chondrocytes largely delays fracture healing and callus mineralization. In contrast, local injection of Yoda1 markedly accelerated fracture healing in bone fracture mice. PIEZO1 activation increases, while PIEZO1 siRNA knockdown decreases, expression of osteogenic markers such as RUNX2, Col1a1 and Osterix in primary human articular chondrocytes (HACs) induced by osteogenesis and fluid shear stress stimuli. Interestingly, we found that Yoda1 reduced, while Piezo1 deletion increased, the expression of Runx2-degraded E3 ligase smurf1 in HACs, inhibits ubiquitin-proteasome degradation of Runx2, and promotes Runx2 transcription and osteogenic phenotype. virtual docking simulation revealed Piezo1 molecule with strong binding ability to RSV. Results from primary HACs showed that RSV activates the PIEZO1-mediated calcium flux. Results from in vitro experiments confirmed that RSV decreased the Runx2 degradation and reversed by Piezo1 deletion in HACs. Hydrogel conjugated with RSV were stable and nontoxic, with long time slow release, high cartilage uptake, and penetration capabilities, and is used for in vivo research. When compared with control mice, the RSV-treated mice displayed marked accelerated fracture healing, and upregulated osteogenic genes. Importantly, RSV-induced increases in the bone trabeculae formation, callus mineralization and fracture gap union were dramatically delayed or completely abolished by Piezo1 deletion.Conclusions We establish a critical role of Piezo1 in promoting bone fracture healing and define RSV, Piezo1-targeted compound, as a potential bone fracture treatment.

SDHA inhibition is involved in Lin28a osteoarthritic chondrocyte reprogramming *ZOHRA BOUCHEMLA[1], Inès Slitine[2], Valentin Duong[2], Fawaz Alzaid[3], Lucie Orliaguet[3], Augustin Latourte[4], Pascal Richette[4], Hang-Korng EA[4], MARTINE COHEN-SOLAL[5], Eric Hay[6]. [1], France. [2]U1132 Inserm, France. [3]Cordeliers Research Center, INSERM, France. [4]U1132 Inserm and Lariboisière APHP hospital, France. [5]Inserm U1132 Bioscar and université Paris-Cité, France. [6]INSERM u1132, France

We have previously shown that Lin28a induces cartilage regeneration during osteoarthritis by inhibiting Let7. Loss of hypoxia is associated with OA progression, inducing energetical metabolism dysfunction. We focused here on the effect of Lin28a on this process and how energetical metabolism is involved in cartilage reprogramming.We performed RNAseq, RT-qPCR, WB, and immunofluorescent staining on murine primary chondrocytes overexpressing or not Lin28a in control or osteoarthritic (Wnt3a) conditions. For ex vivo analysis we used mouse femoral heads and human cartilage explants. Osteoarthritis was induced in WT or TgLin28aflox/flox/Col2CreERt2 by meniscectomy or aging. Knee joints were used for qPCR and histological analysis.In vitro RNAseq analysis showed that Wnt3a induces an increase in oxidative stress associated genes and mitochondrial impairment. Seahorse assay demonstrated a dramatic decrease of the spare respiratory capacity, indicating mitochondrial failure induced by Wnt3a treatment. On the other hand, reduced mitochondrial respiration and increased glycolysis were found with Lin28a overexpression (RNAseq and Seahorse). RNAseq indicates that the mitochondrial enzyme SDHA is oppositely regulated by Wnt3a and Lin28a. In vitro, Wnt3a increases SDHA gene and protein expression whereas Lin28a reduces it. This result was confirmed ex vivo on mouse femoral head explants. In OA mice (meniscectomized or aged), we observe an increase of SDHA expression whereas it is dramatically decreased in TgLin28a mice. This result was confirmed in human OA cartilage samples. To investigate the role of SDHA in chondrocyte protective effect, we used Aptenin5, an SDHA inhibitor. Aptenin5 inhibits the increased expression of mmp13 and adamts5 induced by Wnt3a. This effect was also found in human explants cultured with Wnt3a and Aptenin5. Because SDHA is involved in the conversion of succinate to fumarate, we hypothesized that the accumulation of succinate is responsible for the protective effect on chondrocytes. To demonstrate this, we treated murine chondrocytes and explants with Wnt3a with and without succinate. We found that succinate blocks the pro-catabolic and anti-anabolic effects of Wnt3a.Alltogether, these data indicate that energetic metabolism reprogrammed by Lin28a overexpression participates in cartilage protection during OA through SDHA inhibition. These results suggest that chondrocyte energy metabolism could be a new insight on OA therapeutics.

IL-36Ra modulates IL-1?-induced inflammasome activation in chondrocytes *Sai Rama Krishna Meka[2], Michael Klüppel[2], Pranav Mishra[3], Huseyin Ozkan[2], Esin Ozkan[2], Alfonso Torquati[2], Anna Spagnoli[2]. [2]Rush University Medical Center, . [2]Rush University Medical Center, United States. [3]Rush University,

Background: IL-36 receptor antagonist (IL-36Ra) is emerging as a bone fide anti-inflammatory mediator in injury/damage response, including in osteoarthritisI. IL-36Ra belongs to the IL-36 cytokine family and has been postulated to function as a negative regulator of the IL-36 pro-inflammatory signaling pathway by inhibiting the dimerization of IL-36R and therefore the binding of the other ligands. However, there is emerging evidence that IL-36Ra mediates anti-inflammatory effects independently from IL-36R through interactions with the receptor complex SIGIRR/TIR8II. We hypothesize that IL-36Ra alters inflammatory responses in primary chondrocytes by modulating the gene expression of the IL-1?-induced inflammasome.Methods: Growth Plate Chondrocytes (GPCs) and immature Articular Chondrocytes (iMACs) isolated from P7 mice were treated every other day for a week with IL-36Ra (100 ng/ml) alone; with IL-1? (1 ng/ml) or IL-36? (100 ng/ml) alone and in combination with IL-36Ra (100 ng/ml). Collected mRNAs were subjected to q-RTPCR analysis. Data are expressed as mean + SD, significance was set at $p<0.05$.Results: IL-1? treatment triggered expression of inflammatory response genes such as Mmp13, Nfkbiz (I?B?), Nlrp3 and Irak in both GPCs and iMACs. Interestingly, the inflammatory response observed was several folds higher in iMACs than in GPCs. IL-36Ra exerted a significant reduction in IL-1?-mediated inflammatory gene expression. In particular, IL-36Ra blunted the IL-1? effects on Mmp13, Nfkbiz, Nlrp3 and Irak in GPCs, and on MMP13 and Nfkbiz in iMAC's (Fig 1). Notably, IL-36Ra and IL-36? alone or in combination had not effects, thus highlighting a role for IL-36Ra in response to specific pro-inflammatory environments independently of IL-36? signaling.Conclusion: Our data demonstrate that in chondrocytes, IL-36Ra impairs the IL-1?-induced expression of inflammasome genes. The results suggest that IL-36Ra might have anti-inflammatory effects that are independent of IL-36? signaling. Transcriptomic Analysis of Growth Plate Chondrocytes in G610C Osteogenesis Imperfecta Mice *JOE KODAMA[1], Kevin Wilkinson[2], Masahiro Iwamoto[3], Motomi Enomoto-Iwamoto[4], Sergey Leikin[5], Satoru Otsuru[2]. [1]University of Maryland, Baltimore, United States. [2]University of Maryland, United States. [3]University of Maryland School of Medicine, United States. [4], United States. [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, United States

In addition to bone fragility, short stature is a major symptom in patients with Osteogenesis Imperfecta (OI). Currently, there is no effective treatment to enhance longitudinal bone

growth, mainly due to the unknown pathogenesis of growth deficiency in OI. Therefore, there is an unmet need to identify the mechanisms to develop novel therapies for growth deficiency in OI. Previously, we reported that the growth plates of G610C OI mice have abnormalities such as reduced proliferation, suppressed maturation, and reduced cell turnover. Additionally, dilation of the endoplasmic reticulum (ER) in hypertrophic chondrocytes (HCs) was prominent in G610C mice, suggesting that G610C HCs are exposed to cell stress. Treatment with 4-phenylbutyric acid (4PBA; a chemical chaperone) successfully reduced ER size and enhanced bone growth, supporting that cell stress in HCs plays an important role in the pathogenesis of growth retardation in OI. In this study, to further understand the dysfunction of HCs in the growth plate of 4-week-old G610C and WT mice, we performed single-cell RNA sequencing (scRNAseq) on freshly isolated growth plate chondrocytes and spatial resolution RNA sequencing (srRNAseq) in the growth plate using Visium from 10X Genomics. Transcriptomic analysis of both scRNAseq and srRNAseq revealed the upregulation of genes related to cell stress in HCs from G610C mice compared to those from WT mice. This upregulation was rescued by 4PBA treatment. The Ingenuity Pathway Analysis of the differentially expressed genes in HCs identified upregulation of the unfolded protein response and ER stress pathways in G610C HCs. Interestingly, G610C HCs significantly reduced the expression of Vegfa, which is known to be required to induce blood vessel invasion at the chondro-osseous junction. Visualization of blood vessels by intravenous injection of fluorescein-conjugated dextran in 4-week-old mice revealed that blood vessel formation in the trabecular area was significantly suppressed in G610C mice (Figure). Considering the coupling of angiogenesis and osteogenesis, our findings suggest that HC dysfunction induced by cell stress not only contributes to growth deficiency but also partially contributes to the reduced trabecular bone by suppressing blood vessel formation in G610C mice.

Chondroprotection in murine posttraumatic osteoarthritis: Increasing evidence supporting efficacy of abaloparatide *Samantha H Landgrave[1], Toru Ishii[1], Dana Godfrey[1], Terrin Geohring[1], Honey Hendesi[1], David Villani[1], SRIVIDHYA IYER[2], Karin Payne[1], Michael David[1], Douglas Adams[3], Lacey Favazzo[1], Beate Lanske[4], Michael Zuscik[3]. [1]University of Colorado Anschutz Medical Campus, United States. [2] Univ of Colorado, Anschutz Medical Campus, United States. [3]University of Colorado, United States. [4]Radius Health, Inc, United States

Osteoarthritis (OA) is a painful and debilitating disease involving the degeneration of diarthrodial joints, with the hallmark feature being cartilage loss. Currently, treatment options involve only symptom palliation; the absence of a disease-modifying OA treatment is a critical unmet need. Our prior work explored the activation of the parathyroid hormone receptor type I (PTH1R), which is expressed by articular chondrocytes in OA. We have shown that activation of this receptor by the FDA-approved osteoporosis drug Forteo (teriparatide) prevents chondrocyte hypertrophy and apoptosis while stimulating production of cartilage matrix and supporting a chondroprotective effect in a mouse model of posttraumatic OA (PTOA). Recently, the FDA has approved another PTH1R agonist, Tymlos (Abaloparatide), and we hypothesize that this PTH1R agonist could also be an effective chondroprotective drug in PTOA. To address this hypothesis, we examined the effects of abaloparatide (Abl) on knee cartilage and PTOA progression in mice. Using the widely employed destabilization of the medial meniscus (DMM) surgical approach, we induced knee PTOA in 16-week-old C57BL/6 mice. Beginning at 2 weeks after DMM, 40 µg/kg/day of Abl or saline was injected subcutaneously daily for a total of 6 weeks. Tissues were harvested at 8 weeks after DMM surgery. OARSI scores revealed that Abl provided a whole joint tissue protection that approaches statistical significance (Fig 1A). Closer investigation of tibial cartilage structure revealed significant preservation of the uncalcified cartilage in Abl treated mice (Fig. 1B) as shown by Safranin O/Fast Green stains (Fig. 1C). Bulk RNA sequencing of the whole joint was also performed to identify impacts of Abl on gene expression in joint tissues. The volcano plot displays 160 significant differently expressed genes in the abalo DMM compared to saline DMM knees (Fig. 1D). KEGG analysis showed positive activation of Cell Cycle in Abl-treated mice relative to saline controls, and a select group of other differentially expressed genes are presented that suggest a chondroprotective effect (Fig. 1E). These finding provide the first evidence indicating the efficacy of Abl in providing chondroprotection in murine PTOA. Follow-on studies to more deeply analyze the molecular, cellular, and systemic changes induced by Abl treatment will provide a comprehensive view of its potential disease modifying capability in PTOA.

Hedgehog activation promotes osteogenic cell fates of growth plate resting zone chondrocytes *Shion Orikasa[1], Noriaki Ono[1]. [1]University of Texas Health Science Center at Houston School of Dentistry, United States

The resting zone of the postnatal growth plate is organized by slow-cycling chondrocytes expressing parathyroid hormone-related protein (PTHrP), which include a subgroup of skeletal stem cells that contribute to the formation of columnar chondrocytes. The PTHrP-Indian hedgehog (Ihh) feedback regulation is essential for sustaining growth plate activities; however, molecular mechanisms regulating cell fates of PTHrP+ resting chondrocytes and their eventual transformation into osteoblasts remain largely undefined. In this study, we hypothesized that Hedgehog signaling facilitates osteogenic cell fates of PTHrP+ resting chondrocytes through multiple mechanisms. We utilized a tamoxifen-inducible PTHrP-creER line that can exclusively mark PTHrP+ chondrocytes in the resting zone of the postnatal growth plate without marking any other cell types in long bones. To specifically activate Hedgehog signaling in PTHrP+ resting chondrocytes and visualize the fate of their descendants within growth plate and bone marrow, we also used Patched-1 (Ptch1 encodes a Hedgehog receptor which inhibits its downstream Smoothened signaling) floxed and R26R-tdTomato reporter alleles. All mice received a single dose of tamoxifen at postnatal day (P) 6 and were chased for up to 3 months. Histological and three-dimensional micro-computed tomography (3D micro-CT) analyses were performed at P14, 21, 28, 36, 42, 56, 70, 96. Hedgehog-activated PTHrP+ chondrocytes formed large concentric clonally expanded cell populations within the resting zone ('patched roses') at P21 and generated significantly wider columns of chondrocytes, resulting in hyperplasia of the growth plate at P36. Interestingly, Hedgehog-activated PTHrP+ cell descendants migrated away from the growth plate and eventually transformed into trabecular osteoblasts in the diaphyseal marrow space, leading to increased trabecular bone mass in the diaphysis at P96. Therefore, Hedgehog activation drives resting zone chondrocytes into transit-amplifying states as proliferating chondrocytes and eventually converts these cells into osteoblasts, unraveling a novel Hedgehog-mediated mechanism that facilitates osteogenic cell fates of PTHrP+ skeletal stem cells. These findings provide a solid foundation to understand how therapeutic intervention to the Hedgehog signaling pathway may impact a group of stem cell populations residing in the resting zone of the growth plate of growing individuals and subsequently affect bone formation.

Cbf? inhibits osteoarthritis progression through regulating Runx1 stability

*Xian Jin[1], Xiangguo Che[1], Na-Rae Park[1], Dong-Kyo Lee[1], Poo-Reum Choi[1], Ying Cui[1], Hee-June Kim[2], Hee-Soo Kyung[2], Hyun-Ju Kim[1], Jane B. Lian[3], Janet L. Stein[3], Gary S. Stein[3], Je-Yong Choi[1]. [1]Department of Biochemistry and Cell Biology, Cell and Matrix Research Institute, Korea Mouse Pheno-typing Center, KNU Convergence Educational Program of Biomedical Sciences for Creative Future Talents, School of Medicine, Kyungpook National University, Republic of Korea. [2]Department of Orthopedic Surgery, School of Medicine, Kyungpook National University, Kyungpook National University Hospital, Republic of Korea. [3]Department of Biochemistry and University of Vermont Cancer Center, University of Vermont College of Medicine, United States

Abstract: TGF-? signaling is a vital regulator for maintaining articular cartilage homeostasis. Runx transcription factors, downstream targets of TGF-? signaling, have been studied in the context of osteoarthritis (OA). Although Runx partner core binding factor ? (Cbf?) is known to play a pivotal role in chondrocyte and osteoblast differentiation, the role of Cbf? in maintaining articular cartilage integrity remains obscure. This study investigated Cbf? as a novel anabolic modulator of TGF-? signaling and determined its role in articular cartilage homeostasis. Cbf? significantly decreased in aged mouse articular cartilage and human OA cartilage. Articular chondrocyte-specific Cbfb-deficient mice (Cbfb?ac/?ac) exhibited early cartilage degeneration at 20 weeks of age and developed OA at 12 months. Cbfb?ac/?ac mice showed enhanced OA progression under the surgically induced OA model in mice. Mechanistically, forced expression of Cbf? rescued Type II collagen (Col2?1) and Runx1 expression in Cbf?-deficient chondrocytes. TGF-?1-mediated Col2?1 expression failed despite the p-Smad3 activation under TGF-?1 treatment in Cbf?-deficient chondrocytes. Cbf? protected Runx1 from proteasomal degradation through Cbf?/Runx1 complex formation. These results indicate that Cbf? is a novel anabolic regulator for cartilage homeostasis, suggesting that Cbf? could protect OA development by maintaining the integrity of the TGF-? signaling pathway in articular cartilage.

Severe Hypocalcemia Following Lutetium Lu-177 Vipivotide Tetraxetan: How Does It happen?

*Subarna Dhital[1]. [1]University of Wisconsin-Madison, United States

Introduction: Lutetium Lu-177 Vipivotide Tetraxetan (177Lu-Vipivotide Tet) is a radioligand agent approved for use in adults with prostate-specific membrane-positive metastatic castration-resistant prostate cancer previously treated with androgen receptor pathway inhibition and taxane-based chemotherapy (1). Hypocalcemia has been reported in patients receiving 177Lu-Vipivotide Tet but the responsible mechanism is not well characterized. Clinical Case: A 57-year-old man with metastatic castration-resistant prostate cancer presented with hypocalcemia. His treatment history included leuprolide, docetaxel, abiraterone with prednisone, olaparib and cabazitaxel. He also had prolonged treatment with monthly zoledronate for 4.5 years. Because of disease progression, he was started on treatment with 177Lu-Vipivotide Tet.He presented with acute hypocalcemia shortly following the first dose of 177Lu-Vipivotide Tet. At presentation, his corrected serum calcium was 5.7 mg/dL. For the degree of hypocalcemia, he was rather minimally symptomatic with mild acral paresthesia and masseter muscle spasm. Chvostek's and Trousseau's signs were negative on the physical exam. ECG did not show any QT-interval prolongation.His parathyroid hormone level was robustly elevated at 363 pg/mL (23-97). Concomitant 25(OH) Vitamin D level was 26 ng/mL. Serum creatinine was 0.52 mg/dL. Phosphate was 4.5 mg/dL (2.3-4.7). Recent imaging with PET-CT had shown diffuse, markedly avid sclerotic lesions throughout the visualized skeleton. Pelvic, retroperitoneal, and chest areas showed lymphadenopathy.Another notable lab change was the evidence of tumor response reflected by decreasing serum prostate specific antigen concentration (Figure 1). Additionally, total alkaline phosphatase titers had increased markedly, indicative of an increase in bone formation activity.He was treated with intravenous calcium, oral calcium carbonate and citrate, cholecalciferol, and oral calcitriol. Serum calcium levels gradually normalized. Treatment with 177Lu-Vipivotide Tet was resumed 3 months from the last dose. The magnitude of drop in serum calcium was rather low with subsequent dosages.Clinical Lessons:1. Severe hypocalcemia is a risk in patients receiving 177Lu-Vipivotide Tet.2. Low skeletal calcium reserves from androgen deprivation therapy may be a compounding risk factor.3. The background of anti-resorptive therapy common in this patient population could worsen hypocalcemia by limiting calcium mobilization from the uninvolved bone.4. Supplementing calcium and active vitamin D appears to be a reasonable approach for treating hypocalcemia.5. The risk of hypocalcemia appears to be lower with subsequent doses.References: (1) Sartor O et al. Lutetium-177-PSMA-617 for Metastatic Castration-Resistant Prostate Cancer. Progressive metaphyseal deformities and sclerosis in 11 year fraternal twins with Osteosclerotic metaphyseal dysplasia (OSMD) and Hypophosphatasia (HPP) *Nancy Dunbar[1], Eric Rush[2], Carley Vuillerman[3]. [1]Connecticut Childrens, United States. [2]Childrens Mercy, United States. [3]Boston Childrens Hospital, United States

Osteosclerotic metaphyseal dysplasia (OSMD) is a rare autosomal recessive condition characterized by a distinctive pattern of bony sclerosis limited to metaphyses and undertubulation in the metaphyses and metadiaphyses regions. It is believed to be due to reduced bone resorption by osteoclasts. It is due to biallelic pathogenic variants in the Leucine-rich repeat kinase 1 (LRRK1) gene. There are few cases in the literature and findings are heterogeneous. We report 11 year-old twin sisters with chronic musculoskeletal pain, early tooth loss, frequent fractures and easy fatigability. At age 2 years, they had already lost multiple teeth and sclerotic bones were noted on lower extremity imaging with increased bone mineral density on DXA. Genetic studies for osteopetrosis including CLCN-7, PLEKHM1 and LRP5 were normal. At age 5 years, WES revealed actionable heterozygous variants in the ALPL and TSC2 genes. Treatment for HPP with asfotase alfa was undertaken but discontinued after 9 weeks due to concern for worsening tibial sclerosis.Since the ALPL mutation did not clearly explain the sclerotic bone changes, the WES was re-analyzed at age 8 and results showed that the twins were compound heterozygotes for two mutations in the LRRK1 gene (partial gene deletion and c.5870+1G>C). By age 10, the girls had increasing sclerosis of individual long bones including humeri, femora and tibias with palpable areas of prominence in the metadiaphyseal region that corresponded to areas of bone that are sclerotic and undertubulated. They have experienced symptomatic and asymptomatic fractures in both upper and lower extremities. A bone biopsy with tetracycling labeling will be performed later this month during a planned intramedullary rod surgery. Otherwise, treatment has been supportive including physical therapy and pain control.This report provides additional phenotypic information about LRRK1 mutations and OSMD. It also underscores the importance of revisiting WES results in cases that remain ambiguous to avoid ineffective or deleterious treatments. Further reports documenting the natural history and progression of disease in OSMD are needed as well as basic research into the functional role of LRRK1 in osteoclastic function.

Identification of Novel Somatic Pathogenic Menin 1 Mutations without Germline Origin in an Atypical Parathyroid Tumor *An Nguyen[1], Dolores Shoback[2], Roubin Wu[3], Quan-Yang Duh[4], Janet Chiang[1]. [1]UCSF Endocrinology, United States. [2]UCSF Endocrinology, SFVA Medical Center, United States. [3]UCSF Pathology, United States. [4]UCSF Endocrine Surgery, SFVA Medical Center, United States

Atypical parathyroid tumors (APTs) are rare lesions and can have worrisome features even without invasion or metastases like PT cancer. The loss of parafibromin staining in these tumors suggests a germline or somatic mutation that produces either hyperparathyroidism (HPT)-jaw tumor or familial HPT syndromes. However, parafibromin expression does not exclude a possible mutation.A 69-year-old woman with end-stage renal disease received a living donor kidney transplant after being on peritoneal dialysis for 16 months. While on dialysis and cinacalcet 120mg daily, serum Ca was ~9.0 mg/dL (normal, 8.6-10.4), and PTH values were 1100-1500 pg/mL (normal, 16 -77). One-month post-transplant, PTH remained elevated to 600 pg/mL, serum Ca to 11.8 mg/dL. Neck ultrasound identified a 1.9 x 1.8 x 2.2 cm left posterior hypoechoic candidate lesion with heterogeneity and irregular borders which was co-localizied on Sestamibi scan. PTH level in the washings of the fine needle aspiration of this lesion was >2500 ng/L. At left neck exploration, a large superior parathyroid gland was found to be embedded in the thyroid, requiring lobectomy with parathyroidectomy. Histology revealed a markedlyn enlarged glandtumor with 95% cellularity, without significant mitotic activity, necrosis or infiltration into surrounding tissue. There was retention of nuclear parafibromin staining, consistent with APT. Postoperatively, PTH decreased to 140 pg/mL (serum Ca 9.7 mg/dL) off cinacalcet. The patient denied any family history of MEN. Molecular testing of the tumor revealed pathogenic missense Menin 1 mutation MEN1 p.P320L (40% allele frequency) and pathogenic frameshift MEN1 p.V80W (38% allele frequency) - the latter being a novel mutation. Germline genetic testing was negative for both variants.For molecular testing for somatic mutations, the general cutoff of at least 50% allele frequency strongly supports a germline origin. The MEN1 p.P320L missense mutation is known to result in reduced protein stability leading to rapid degradation and is a germline mutation in hereditary MEN1 and a somatic mutation in sporadic endocrine tumors. The p.V80W mutation in MEN1 is novel and predicted to be pathogenic, given its truncating effect potentially early in protein translation. Overall, this case unites several concepts of recognition, diagnosis, and treatment, as well as application of molecular and genetic testing to identify somatic and germline mutations in APT and in endocrine tumors.

Primary Hyperparathyroidism Presenting with Acute Gout in a Pregnant Female *Keun Young Kim[1], Safiya Elahi[1], sanford Baim[1]. [1]Rush University Medical Center, United States

Introduction: Primary hyperparathyroidism (PHPT) is characterized by elevated serum calcium and elevated or inappropriately normal parathyroid hormone (PTH). Incidence of PHPT in pregnant females is very rare (1%). Musculoskeletal complaints due to pseudogout or gout may be associated with PHPT but are rarely initial presenting symptoms. To our knowledge, there are no reported cases of PHPT presenting as polyarticular gout during pregnancy. We present a rare case of acute gout in a pregnant female that was diagnosed and successfully treated.Case:A 29-year-old pregnant female (17 weeks gestational age) presented with left hand pain, painful lower extremity swelling, and inability to ambulate. Lab results disclosed a calcium of 11.9 mg/dL (9.1-11.2 mg/dL), ionized calcium 1.44 mmol/L (0.95-1.32mmol/L) and inappropriately normal PTH of 61.9 pg/mL (8.0-85.0 pg/mL). C-reactive protein and erythrocyte sedimentation rate were notably elevated. Physical exam revealed pain on motion and palpation, soft tissue swelling and warmth of the left second and third metacarpals, left knee, and both ankle joints. Neck ultrasound showed a right-sided lesion inferior to the thyroid. Left knee arthrocentesis revealed negative birefringent needle-shaped crystals on polarized light microscopy, confirming the diagnosis of gout. The patient underwent resection of the right inferior parathyroid gland; histology confirmed a parathyroid adenoma. Serum calcium levels normalized post-operatively and all joint symptoms resolved on prednisone.Discussion:PHPT in pregnant women is rare and can be complicated by several normal physiologic changes that occur during pregnancy. These include hemodilution, a lower proportion of bound calcium due to reduced albumin levels, and inhibition of PTH-mediated bone resorption by estrogen. Given these multiple effects on serum calcium levels, mild hypercalcemia due to PHPT may go unnoticed during pregnancy with untreated PHPT increasing maternal and neonatal morbidity and mortality.Polyarticular gout is a highly unusual presentation of PHPT. Recognition of both conditions, timely diagnostic studies, and interdisciplinary management were necessary to allow our patient to undergo a successful parathyroidectomy during her second trimester. This case highlights the necessity of monitoring serum calcium, maintaining high suspicion of PHPT when the former is elevated in pregnant patients, and being aware of unusual presentations of PHPT.

A stunning case of symptomatic hypocalcemia in a normocalcemic patient *Niloofar Mirsaidi[1], Avani Sinha[1]. [1]Northwell Health - North Shore/LIJ, United States

Introduction: Hypoparathyroidism is a common complication of thyroidectomy and may occur as a result of parathyroid dysfunction from parathyroid injury, disruption in parathyroid blood supply or inadvertent parathyroidectomy. Also known as parathyroid "stunning", transient hypoparathyroidism can result in subsequent hypocalcemia, hypomagnesemia and hyperphosphatemia due to disruption of PTH release and/or production. We discuss a case of hypocalcemia despite normal serum calcium levels in a woman who underwent thyroidectomy and parathyroidectomy with parathyroid reimplantation. Clinical case: A 46-year-old female with PMH of Hashimoto's thyroiditis, thyroid papillary microcarcinoma s/p total thyroidectomy and parathyroidectomy with parathyroid reimplantation, and GERD (on PPI) presented to the ED on POD #3 with worsening bilateral extremity and periorbital numbness suggestive of post-operative hypocalcemia. In the ED, vital signs were normal. Physical exam was notable for decreased tactile sensation in all extremities and positive Chvostek sign bilaterally. Labs showed serum calcium level of 8.5 mg/dL (8.5-10.1 mg/dL), ionized calcium 1.04 mmol/L (1.15-1.33 mmol/dL), intact PTH 4 pg/dL (15-65 pg/dL), and magnesium 1.8 mg/dL (1.6-2.6 mg/dL). Vitamin D levels were normal and phosphorus was elevated. ECG was unremarkable. On arrival to the ED, she was given calcium and calcitriol at doses 25% and 100% greater than her home doses, respectively, and magnesium supplementation was started to keep magnesium > 2.0 mg/dL. Her ionized calcium transiently improved but decreased again to 1.09 mmol/L, yet she reported improved symptoms. After discharge, outpatient labs showed normalization of calcium, PTH, magnesium and phosphorus with associated symptomatic improvement, and supplement doses were decreased accordingly. Conclusions: Parathyroid gland manipulation may cause transient hypoparathyroidism, yet signs and symptoms of hypocalcemia would not be expected with normal serum calcium and mildly decreased ionized calcium. Our patient's presentation was likely due to her body reacclimating to new "normal" levels of PTH and calcium. Higher doses of calcium and calcitriol supplementation may thus be needed postoperatively in certain cases. Magnesium supplementation may further assist in PTH modulation. Furthermore, in patients chronically using PPIs, intestinal calcium absorption may be decreased warranting medication reevaluation at the time of surgery.

Bone microarchitecture and disorganized bone tissue in a young woman with pycnodysostosis and an atypical femur fracture: A case report *Cat Shore-Lorenti[4], Heshan Witanachchi[4], Colin Chen[4], Simon Zhang[4], Hanh Nguyen[2], Christian Girgis[3], Roger Zebaze[4], Peter Ebeling[5]. [4]Monash University, Australia. [2], Australia. [3]Westmead Hospital , . [4]Monash University, . [5]School of Clinical Sciences, Monash University, Australia

Abstract: Pycnodystosis (PYCD) is a rare autosomal recessive lysosomal storage disorder, involving a loss of function mutation of the gene encoding cathepsin K (CTSK). The loss of function of this osteoclastic lysosomal protease reduces bone resorption, increases bone mineral density (BMD), but impairs the structure and material properties of bone. This case report demonstrates that bone fragility in a young woman with PYCD, presenting with an atypical femur fracture (AFF), was not explained by changes in bone density but by microarchitectural defects, disorganized bone and microcracks.Clinical Case: A 24-year-old woman with PYCD presented with an AFF in 2020 following a long history of prior minimal trauma fractures (MTF). PYCD was diagnosed in childhood and as an adult this patient displayed several signs and symptoms, including, but not limited to: short stature; dystrophic nails; short fingers; prominent forehead; prognathism, and; a significant history of 10 peripheral MTFs. Her first MTF occurred at 6-years-of-age. No other medical conditions or significant family history were identified. Her parents were consanguineous.At the time of the AFF, the patient was treatment naïve. Three years prior she gave birth via Caesarean-section and was able to breastfeed her baby for 12 months. Following the AFF, her vitamin D was slightly reduced (45 nmol/L), while P1NP and CTX were high, at 124 ug/L and 518 ng/L, respectively. Other pathology results were unremarkable.In the year following the AFF, BMD was high at the spine (T-score = +3.3), total hip (+5.4); and femoral neck (+6.7). High-resolution peripheral quantitative computed tomography (HR-pQCT) of the distal tibia detected unexpected cortical lucencies and sclerotic lesions in the trabecular compartment of the distal tibia (Fig1). Both total and trabecular volumetric BMD (vBMD) were high and trabecular numbers were increased in both the distal radius and tibia. Disorganization analysis using a novel software showed chaotically disorganized femoral shaft with spike shape masses at locations corresponding to a pseudofracture and sclerotic lesions.Clinical Conclusion: These imaging techniques detected disorganized bone and microarchitectural defects in a treatment naïve patient with PYCD and an AFF. The suppression of bone resorption in PYCD allows the accumulation of microdamage and disorganized bone that produces bone fragility. Antiresorptive therapy should be avoided.

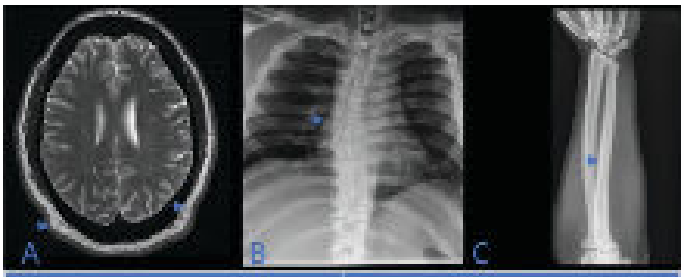
Autosomal Dominant Osteopetrosis, Chiari Malformation and Recurrent Nephrolithiasis: A Rare Association *Joseph Arguinchona[2], Samir Ahmed[2], Krupa Doshi[2]. [2]Mayo Clinic Arizona, United States. [2]Mayo Clinic Arizona,

Background: Osteopetrosis (OP) is a rare, heritable metabolic bone disorder characterized by dense but brittle bone. Rarely, OP is associated with Chiari malformation, described in a handful of case reports. Renal manifestations of osteoporosis are not well documented, with rare case reports of nephrolithiasis. Here we present a patient with a Chiari malformation and recurrent nephrolithiasis who was subsequently diagnosed with autosomal dominant OP.Case Report: A 44-yo white male presented with a DXA scan showing lumbar spine, and left femur neck T-scores of 9.6 and 7.6 respectively. His past history was significant for development of a slipped capital-femoral epiphysis in the right hip at age 13y, requiring pinning. After insidiously presenting with upper back and nuchal pain since late childhood, he was diagnosed with Chiari malformation at age 30y. Surgical correction resulted in complete resolution of pain. In his mid-30's, he developed recurrent nephrolithiasis. He underwent right total hip replacement of previously pinned hip at age 40y. Operative repair was challenging as his bone was very hard and resistant to drilling, and he developed right foot drop postoperatively. He underwent left hip replacement due to severe osteoarthritis at age 43y. Other comorbidities include left tinnitus and progressive hearing loss, hepatic steatosis, hepatomegaly at age 32y, and type 2 diabetes diagnosed at age 41y. He had no known family history of sclerosing bone disease with limited contact with the paternal side of his family. Laboratory findings were unremarkable except for vitamin-D deficiency (Table 1). Stone analysis revealed mixed uric acid and calcium oxalate stones (80%/20%). MRI brain (w/wo contrast) showed diffuse, symmetric thickening of the calvarium. A skeletal survey demonstrated diffusely thickened cortices involving the calvarium, ribs, radius/ulna, and femora supporting a diagnosis of OP. Genetic testing showed a pathogenic variant in the LRP5 gene confirming a diagnosis of autosomal dominant OP.Learning points: OP is a rare sclerosing bone disorder. This case highlights its broad clinical spectrum which includes Chiari malformation and recurrent nephrolithiasis. In addition, expansion of bone into marrow cavities and cranial foramina may result in extramedullary hematopoiesis leading to hepatomegaly and deafness respectively, as experienced by our patient.



D	Results
Sodium (135 - 145 mmol/L)	137
Chloride (98 - 107 mmol/L)	101
Potassium (3.6 - 5.2 mmol/L)	4.7

Evidence of Reduced Dentin Sialophophoprotein Expression and Impaired Cell Process Formation in Odontoblasts in Patients with Hypophosphatasia *Akira Nozoe[1], Kazuaki Miyagawa[1], Chiho Nakano[1], Shinji Takeyari[2], Makoto Fujiwara[4], Yasuhisa Ohata[4], Keiichi Ozono[2], Takuo Kubota[2], Susumu Tanaka[1]. [1]First Department of Oral and Maxillofacial Surgery, Osaka University Graduate School of Dentistry, Japan. [2]Osaka University Graduate School of Medicine, Japan. [4]Osaka University, . [4]Osaka University, Japan

Background: Hypophosphatasia (HPP) is a genetic disorder characterized by the premature loss of deciduous teeth due to defects in cementum formation. In addition, insufficient calcification of mantle dentin, which is essential for cementum formation, is also observed. But the underlying pathology remains unclear. Our objective of this study is to elucidate the underlying pathogenesis of dental defect in patients with HPP.Methods: We utilized induced pluripotent stem cells (iPSCs) from healthy individuals to generate odontoblast-like cells (ODs) via neural crest cells and mesenchymal stem cells (MSCs). We then examined various parameters, including odontoblastic differentiation markers and protein expressions, morphology, and calcification function using RT-qPCR, western blotting, immunostaining, and alizarin red staining. As a control group, we also induced osteoblast-like cells (OBs) from the same healthy MSCs. In addition, we created an HPP-iPSC from a patient with perinatal severe-type HPP (c.1559delT/c.1559delT: Perinatal), genetically rescued Perinatal-iPSCs by repairing both alleles using the CRISPR-Cas9 system (WT/WT: resHPP), and an odonto-type HPP model (WT/c.550C>T: odonto) from the resHPP-iPSCs using prime editing. We then assessed their isogenic odontogenesis.Results: In WT-ODs, we observed significant increase in DSPP and NES protein expressions, compared to MSCs. The expression of RUNX2 protein increased in the early differentiation stages and then decreased in the late differentiation stages. Additionally, calcification and ALP activity increased over time. We

also noted significant increase in MAPT and NEFL gene expressions, in WT-ODs compared to WT-OBs. Moreover, WT-ODs displayed a polarized nucleus and elongated cell process in one direction, Compared to Perinatal-ODs and Odonto-ODs, resHPP-ODs showed significant increase in ALP activity, DSPP protein expression, and mineralization during odontogenesis. Notably, RUNX2 protein expression was sustained until the late differentiation stage in Perinatal-ODs. The length of cell processes in Perinatal-ODs and Odonto-ODs were shorter than that in resHPP-ODs.Conclusion: We successfully established ODs differentiated from iPSCs. Our findings suggested that reduced DSPP expression, decreased ability to form cell process and lower calcification ability may be involved in the underlying pathogenesis of dental defect in HPP.

SUN-153

Comparison of Cd11b+ cells of the mandibular and femoral bone marrow at single-cell resolution *Rachel Phillips[1], Elizabeth Bradley[1], Kim Mansky[2], Amy Tasca[1]. [1]University of Minnesota , United States, [2]University of Minnesota, United States

Osteoclast activity within craniofacial bones orchestrates critical processes such as tooth eruption and skull modeling. Recent lineage tracing experiments in mice demonstrate that proper tooth eruption and skull generation requires embryonic but not adult myeloid cells. These data suggest that cellular ontogeny imparts fundamental differences between adult bone marrow-derived as compared to embryonic-derived tissue resident osteoclast progenitor cell populations; however, we lack essential knowledge about the osteoclast progenitors found in the marrow of craniofacial bones. Moreover, we completely lack transcriptomic data describing craniofacial-derived osteoclast progenitors. This knowledge gap impairs our understanding and treatment of pathological conditions including osteonecrosis of the jaw, primary or metastasized facial bone malignancies and osteomyelitis. Our lab has demonstrated that mandible-derived osteoclast precursors proliferate less, have increased osteoclast size and upregulation of osteoclast genes including Nfatc1, Dc-stamp, Ctsk, and Rank compared to osteoclasts derived from the femur bone marrow. To develop a better understanding of the transcriptome differences between mandible- and femur-derived osteoclast precursors, we performed scRNA sequencing of CD11b+ cells from mandible and femur bone marrow. CD11b+ cells were isolated from the femur and mandible derived bone marrow of 2-month-old male C57Bl/6 mice using Cd11b+ isolation microbeads. Six samples (3 femoral and 3 mandibular) were submitted for single-cell RNA sequencing. Six single cell captures targeting 10,000 cells each were performed by ST G chip for 3' gene expression. Using two-dimensional t-SNE representations of the expression levels of each of the samples, unique cell populations and differentially expressed genes were identified. Femur gene expression levels were used as the baseline for analysis. Differentially expressed genes pathways included up-regulation of TNF-?, AGE-RAGE and FOXO signaling pathways. While genes involved in cell adhesion, Fc gamma R mediated phagocytosis and autophagy pathways were down regulated in mandible derived cells. Currently expression of genes within these pathways are being verified by qRT-PCR. Together this data suggests that mandible derived osteoclast precursors have a unique gene signature compared to femur derived osteoclast precursors.

Age-dependent bone formation capacity in the mouse ligature-induced periodontitis model *Mizuho Kittaka[1], TETSUYA YOSHIMOTO[2], Marcus Levitan[1], Roy Choi[3], Anne Gingery[4], Alexander Robling[1], Yasuyoshi Ueki[5]. [1]Indiana University, United States, [2]University of Missouri-Kansas City School of Dentistry, United States, [3]Indiana University School of Medicine, United States, [4]Mayo Clinic, United States, [5]Indiana University School of Dentistry, United States

Periodontitis is an inflammatory disease of the periodontal tissue caused by bacteria. It is well known that susceptibility to alveolar bone loss in periodontitis increases with age. However, the mechanism by which aging exacerbates alveolar bone loss remains unknown. To investigate this age-dependent mechanism of alveolar bone loss, we applied the ligature-induced periodontitis (LIP) model to young (2.5 months old) and mature (8 to 12 months old) mice. Alveolar bone volume (BV) was assessed by microCT at 5 and 14 days after ligature placement. The magnitude of alveolar bone loss compared to the unligated side was comparable between young and mature mice. Surprisingly, the reduction of BV at day 5 was fully recovered by day 14 in young mice. However, no such recovery was observed in mature mice. Dynamic histomorphometry of alveolar bone between days 6 and 10 showed that ligature placement promoted bone formation in both young and mature mice. However, mineral apposition rate (MAR) and bone formation rate (BFR) were lower in mature mice than in young mice. In contrast, the level of osteoclast induction at day 5 was comparable between young and mature mice. These results suggest that impaired bone formation capacity of osteoblasts is a cause of the lack of BV recovery in mature mice, resulting in sustained bone loss. Next, we hypothesized that decreased osteoblast function in mature mice may be due to a pre-existing condition that increases the accumulation of senescent cells in periodontal tissues. qPCR analysis of periodontal tissues revealed that mature mice expressed senescence marker genes (Cdkn2a and Bcl2) and senescence-associated secretory phenotype (SASP) genes (Il17a, Cxcl1, Tnf, and Il1b) at higher levels than young mice, indicating that the accumulation of senescent cells is increased in periodontal tissues of mature mice. Thus, we found that aging affects the bone formation capacity of osteoblasts during LIP and that there is a concomitant accumulation of senescent cells in periodontal tissues. These data suggest that decreased bone formation capacity with age may contribute to increased susceptibility to alveolar bone loss in periodontitis. Furthermore, since pro-inflammatory SASP molecules are known to inhibit osteoblast differentiation and function, depletion of senescent cells by senolytic drugs may be a therapeutic approach to protect against alveolar bone loss in periodontitis, especially in an aging population.

Development of Cu application using dual-energy computed tomography for detecting medication-related osteonecrosis of the jaw *Satomi Arimoto[1], Akishige Hokugo[1], Kazuki Shigenaga[2], Masahiro Kubo[2], Taro Inagaki[1], Takumi Sato[2], Yujiro Hiraoka[2], Daisuke Takeda[2], Takumi Hasegawa[2], Kiyosumi Kagawa[3], Masaya Akashi[2]. [1]University of California, United States, [2]Kobe University Graduate School of Medicine , Japan, [3]Center for Radiology and Radiation Oncology, Kobe University Hospital, Japan

Introduction: The present study developed an application using dual-energy computed tomography (DECT) focused on Cu for detecting medication-related osteonecrosis of the jaw (MRONJ). Materials and Methods: First, we performed two types of phantom studies using a Cu wire syringe and pig mandible with Cu wire to detect Cu on DECT. Second, DECT examinations of 44 patients with MRONJ were performed to compare lesion and normal bone sites using single-energy CT, DECT, and DECT-Cu applications. Quantitative analyses of the virtual non-calcium CT (VNCa CT) and CT values were performed, and a cut-off value was calculated using receiver operating characteristic analysis. Third, we compared the Cu content in the MRONJ and normal bone groups using inductively coupled plasma atomic emission spectroscopy (ICP-AES). Results: The material-specific differences in attenuation between the two different energies enabled the accurate separation of Cu from Ca in phantom studies. The sensitivity and specificity for single-energy CT, DECT, and DECT-Cu applications were 97.7% and 13.6%, 75% and 81.8%, 81.8%, and 95.5%, respectively. Thus, VNCa CT values obtained on DECT-Cu application images showed the highest area under the curve value and maximal diagnostic efficacy in differentiating lesion sites from normal bone sites. On ICP-AES analyses, the Cu content was significantly higher in the MRONJ group than in the normal bone group. Conclusion: DECT-Cu application demonstrated better diagnostic performance in detecting MRONJ compared with single-energy CT or DECT.

Long-Duration Type 1 Diabetes Reduces Resistance to Damage Accumulation in Femoral Cortical Bone in Older Adults *Shannon Emerzian[1], Jarred Chow[1], Ramina Behzad[2], Daniel Brooks[3], I-Hsien Wu[4], John Gauthier[4], Surya Jangolla[4], Marc Gregory Yu[5], Hetal Shah[5], George King[5], Fjola Johannesdottir[6], Lamya Karim[2], Elaine Yu[7], Mary Bouxsein[8]. [1]Beth Israel Deaconess Medical Center, United States. [2]University of Massachusetts Dartmouth, United States. [3]BIDMC/MGH, . [4]Joslin Diabetes Center, United States. [5]Joslin Diabetes Center, Harvard Medical School, United States. [6]Beth Israel Deaconess Medical Center & Harvard Medical School , . [7]Massachusetts General Hospital, United States. [8]Beth Israel Deaconess Medical Center, Harvard Medical School, United States

While type 1 diabetes (T1D) is associated with an increased risk for hip fracture compared to non-diabetics, the factors contributing to skeletal fragility in T1D are not well understood. Previously we demonstrated a reduction in the post-yield properties of cortical bone, suggesting T1D may alter collagen and reduce the ability of cortical bone to resist damage accumulation. To test this hypothesis, cyclic cortical bone material properties and collagen crosslinks were assessed in the excised femora of older adults with T1D and non-diabetic controls.Whole femora were acquired post-mortem from Joslin Medalists, a cohort of individuals with T1D >= 50 years (n=20); non-diabetic control femora of similar age and sex were obtained from a tissue bank (n=14). Impact microindentation (Osteoprobe, Active Life Scientific) was performed on the anterior diaphysis to quantify the Bone Material Strength index (BMSi). Cortical beams (2x2x40mm) were extracted from the midshaft for damage accumulation testing. Fluorescent advanced glycation end products (fAGEs) were quantified by a fluorometric assay and the crosslink pentosidine (PEN) was quantified by HPLC. For damage accumulation testing, beams were cyclically loaded in 4 point bending with incrementally greater displacements (i.e., damage cycles; from 75% to 200% yield displacement in 25% increments). Following each damage cycle, tangent stiffness and percent stiffness degradation relative to baseline were calculated. Mann-Whitney U tests assessed group differences.The T1D group included 11 women and 9 men with an average (mean+/-SD) HbA1c=7.7+/-1.1%, T1D duration=67.5+/-6.0 years, age at onset=12.8+/-7.9 years, and age at death=80.3+/-8.2 years (range 68-92). The control group was 8 women and 6 men; age (p=0.58) and sex (p=0.90) did not differ between groups. BMSi and fAGEs did not differ between groups. PEN was greater by 17% in T1D (p=0.04). At 200% yield displacement, stiffness degradation from baseline was greater in T1D (14%) versus control (10%, p=0.06; Figure). Although no specimens failed in the control group, 25% of T1D specimens failed at or before 200% yield displacement (Figure). Stiffness degradation was not associated with fAGE (r2=0.001, p=0.87) or PEN content (r2=0.001, p=0.92).Long-duration T1D altered the ability of cortical bone to resist damage accumulation induced by cyclic loading. Further investigation is necessary to determine the cause of reduced resistance to damage accumulation in T1D.

The NAD salvage pathway in osteoblast lineage cells is indispensable for skeletal homeostasis *Olivia Reyes-Castro[1], Aaron Warren[1], Ha-Neui Kim[2], Maria Jose Almeida[3]. [1]University of Arkansas for Medical Sciences, United States. [2]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States. [3]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, United States

Nicotinamide adenine dinucleotide (NAD+) - a critical cofactor for cellular energy metabolism and numerous cellular processes, including cell division, DNA damage repair, and mitochondrial function - can be synthesized via several pathways. NAD+ levels and the expression of nicotinamide phosphoribosyltranferase (Nampt), the rate limit enzyme of the NAD+ salvage pathway, are lower in osteoblastic cells from old when compared to young mice. Moreover, administration of NAD+ precursors to aging mice attenuates the loss of bone mass and the involution of many other tissues. To examine the role of Nampt in osteoblastic cells and whether a decline in Nampt could contribute to skeletal aging, we initially generated mice lacking Nampt in Prx1-cre targeted cells. However these mice exhibited severe developmental phenotypes due to effects in chondrocytes, which precluded the examination of effect of Nampt on bone formation. In the work reported herein, we crossed Nampt-flox and Osx1-Cre mice to generate Nampt?Osx1 and Osx1-cre control mice. Nampt?Osx1 mice were born at the expected Mendelian ratio and were grossly undistinguishable from Osx1-Cre control littermates at birth. Evaluations of body weight, as well as spine and femur DXA BMD at 4 weeks of age revealed no differences between Nampt?Osx1 female or male mice when compared to the respective littermate controls. In contrast, femoral BMD in male and female Nampt?Osx1 mice was decreased at 12 weeks of age compared with Osx1-cre mice. Cultures of bone marrow derived osteoblastic cells from Nampt?Osx1 mice had lower NAD+ levels and exhibited decreased mineralization, as determined by Alizarin Red staining. Micro-CT analysis of femur from male and female Nampt?Osx1 revealed a decrease in cortical thickness due to a decrease in periosteal circumference. No changes were detected at the endosteal circumference. Trabecular bone volume at the distal femur and vertebrae (L5) was also lower in male Nampt?Osx1. These changes were due to a decrease in both trabecular number and thickness. No differences in trabecular bone were found in female. These results indicate that in osteoblast lineage cells Nampt contributes to bone homeostasis. Together with the earlier findings in Nampt?Prx1 mice, these results highlight that the dependency of osteoblast on Nampt is of much lower magnitude than that of chondrocytes.

Tanycytic Thyroid-stimulating Hormone Receptor Activation Increases Blood-hypothalamus Barrier Permeability and Induces Appetite in Female Mice *Hasni Kannangara[1], Jocoll Burgess[1], Sari Miyashita[2], Anisa Gumerova[3], Funda Korkmaz[3], Ronit Witztum[2], Steven Sims[1], Uliana Cheliadinova[1], Georgii Pevnev[1], Ofer Moldavski[3], Tal Frolinger[3], Tony Yuen[4], Ki Goosens[4], Vitaly Ryu[5], Mone Zaidi[6]. [1]Associate Researcher-MSH/QHC/ELM, United States. [2]Postdoctoral Fellow-MSH, United States. [3]Instructor-MSH/QHC/ELM, United States. [4]Associate Professor-MSH/QHC/SSVS/ELM, United States. [5]Assistant Professor-MSH/MSQ/QHC/SSVS/ELM, United States. [6]Professor-MSH/QHC/ELM, United States

In addition to its well-known action to trigger thyroid hormone production, thyroid-stimulating hormone (TSH) is released in the brain, and its receptor (TSHR) has been found in brain sites, including the tanycytes of the third ventricle, that regulate ingestive behavior and convey metabolic information across the blood-hypothalamus barrier (BHB). Our recent work highlights largely undiscovered role for TSHRs in the tanycytes. Here, we tested the hypothesis that tanycytic TSHR activation triggers rapid remodeling of BHB vascular permeability inducing appetite. We compared hypothalamic vascular permeability of food deprived (FD) and ad libitum fed (AL) Tshr+/- and their wild type (WT) counterparts exploiting transmission electron microscopy studies and immunofluorescence for constitutive tight junction protein Claudin-1 and homodimer glycoprotein MECA-32, primarily expressed in tanycytes and endothelial cells, respectively. Fasting significantly increased the organization of tanycytic honeycomb pattern of Claudin-1 and fenestral MECA-32-associated diaphragms in the median eminence and arcuate nucleus implying decreased BHB vascular permeability in Tshr+/- mice. Transmission electron microscopy confirmed immunofluorescence results. In a separate gain-of-function experiment, TSHR activation by the small molecule MS438 increased BHB vascular permeability as evidenced by decreased Claudin-1 and MECA-32 immunostaining. Tanycytic TSHR activation significantly increased both food foraging and intake as during one-hour refeeding after FD. Surprisingly, refeeding restored neuronal activation marker c-Fos expression in the paraventricular nucleus of the hypothalamus, parabrachial nucleus and nucleus of the solitary tract, though failed to do so in the paraventricular nucleus and nucleus of the solitary tract of MS438-injected mice. Collectively, these data infer that modulation of tanycytic TSHRs plays an important role in BHB plasticity in relation with ingestive behavior.

Org43553, the First Low-Molecular-Weight Agonist of the Human Luteinizing Hormone Receptor, Reduces Body Fat. *Daria Lizneva[2], Anisa Gumerova[2], Kseniia Ievleva[2], Orly Barak[2], Funda Korkmaz[2], Judit Gimenez Roig[2], Tal Frolinger[2], Georgii Pevnev[2], Farhath Sultana[2], Darya Vasilyeva[2], Anne Macdonald[2], Natan Kramskiy[2], Soleil Wizman[2], Michelle Orloff[2], Anusha Rani Pallapati[2], Satish Rojekar[2], Vitaly Ryu[2], Ofer Moldavski[2], Tony Yuen[2], Mone Zaidi[3]. [2]Icahn School of Medicine at Mount Sinai, United States. [2]Icahn School of Medicine at Mount Sinai, . [3]Mount Sinai Medical Center, United States

We provide compelling evidence that LH is a pro-lean hormone, and that ORG43553, the first low-molecular-weight agonist of the luteinizing hormone receptor (LHCGR) induces leanness and promotes energy expenditure in mice. We detected Lhcgr transcripts in white adipose tissue (WAT) depots in male and female C57BL/6 mice (qPCR, IHC, RNAscope, Sanger sequencing), but not in Lhcgr-/- mice. Intraperitoneal AlexaFluor-488-labeled hCG bound to gonadal and subcutaneous fat pads in wild type mice, but not in Lhcgr-/- mice. Following i.v. 89Zr-LH injection, radioactivity was detected in mesenteric, inguinal and gonadal WAT. LH, hCG and ORG43553 rapidly induced ERK1/2 phosphorylation in differentiated 3T3.L1 cells. Female and male Lhcgr+/- mice on normal chow and high-fat diet, respectively, became obese, importantly, without changes in sex steroids. The gene-dosage effect of Lhcgr depletion suggests a dominant physiologic action of LH on body composition. 14-week-old male C57BL/6 mice were fed on high-fat diet and injected, i.p., with LH, hCG or vehicle, twice-a-week, for 6 weeks. Both LH and hCG markedly reduced body fat accrual (qNMR) but triggered a rise in serum testosterone. The hCG-induced lean phenotype persisted despite androgen receptor blockade by flutamide-confirming that the pro-lean actions of LH and hCG were largely independent of testosterone. Furthermore that LH failed to inhibit fat accrual in Lhcgr-/- mice testified to its action via the LHCGR. Injection of ORG43553 into male C57BL/6 mice for 9 weeks caused a significant reduction in fat mass (qNMR), with reduced WAT weight in fat depots. Remarkably, serum testosterone remained unchanged confirming that the anti-adiposity effect of ORG43553 was independent of testosterone. To study the mechanism of LHCGR activation on body fat, 3T3.L1 adipocytes were treated with hCG or ORG43553 for 12 hours. This resulted in reduced oil droplet accumulation. 3T3-L1-derived organoids treated with LH, hCG or ORG43553 also displayed a substantial reduction in the differentiated layer compared to vehicle-treated organoids. To study whether, in addition to reducing adipocyte differentiation, LHCGR agonism also enhanced thermogenesis, 3T3-L1 adipocytes were pretreated with ORG43553 for 1 hour before measuring oxygen consumption rate (OCR) on a Seahorse Xf96 Analyzer. ORG43553 increased OCR at baseline and upon oligomycin exposure, indicating mitochondria proton leak (thermogenesis). To confirm increased energy expenditure in vivo, mice were injected, s.c., with ORG43553 or vehicle. Oxygen consumption (VO2) and energy expenditure (EE) increased acutely in ORG43553-treated mice, with no change in locomotor activity. The findings suggest that ORG43553, which has been tested in humans for infertility, can potentially become a candidate drug for obesity.

High Fat Diet-induced Bone Loss is Mediated via RANKL-induced Activation of IL1? and TNF? Signaling in Male Mice. *Aruljothi Muralidharan[1], GUSTAVO GOMEZ[2], Chandrasekhar Kesavan[3], Sheila Pourteymoor[4], Destiney Larkin[4], Franklin V Sechriest[4], Subburaman Mohan[3]. [1]LLVARE, United States. [2], . [3]Jerry L. Pettis Memorial VA Medical Center, United States. [4]VA Loma Linda Healthcare System, United States

Obesity and its metabolic complication of type 2 diabetes are recognized as risk factors for bone fragility and osteoporotic fractures. Our research previously demonstrated that high-fat diet (HFD)-induced obesity in adult mice reduced trabecular bone mineral density (BMD) and increased marrow adipose tissue (MAT) only in male mice. To understand this gender-specific effect of a HFD on MAT and BMD phenotypes, we focused on RANKL signaling since its activation is central to obesity-associated metabolic disorders and negatively regulated by estrogen. In this study, we tested the hypothesis that the activation of RANKL signaling causes HFD-induced bone loss. HFD was associated with a 2.9-fold increase in expression of Tnfsf11 (which encodes RANKL) (P<0.01), in the bones of male mice only. Since bone marrow stromal stem cells (BMSC) are common precursors for osteoblastic and adipocytic lineages, we evaluated the expression of Tnfsf11 and Tnfrsf11b during differentiation in vitro. After treatment of BMSCs with osteogenic media, Tnfsf11 expression was decreased by 40% and 90% (P<0.01) on days 3 and 7, respectively, while Tnfrsf11b expression was unchanged. By contrast, adipogenic media treatment of BMSCs increased Tnfsf11 expression 2.8-fold (P<0.01) and decreased Tnfrsf11b expression by 90% (P<0.001) on day 1. RANKL/OPG ratio remained elevated throughout adipocyte differentiation. RANKL treatment suppressed differentiation of BMSCs towards osteoblasts as revealed by markedly decreased expression of Osx, Runx2, Dlx3, Dlx5, and Bsp by 34%-66% (P<0.01) as early as 6 hrs and remained suppressed during the 72 hrs of treatment. By contrast, expression levels of Il-1? and Tnf? were increased by 99-fold and 65-fold, respectively, at 6 h after RANKL treatment in osteogenic media, while expression levels of Mcp1 and Il-11 were unaffected. We next used neutralizing antibodies to IL-1? and/or TNF? to determine the role of these cytokines as effectors of RANKL on osteoblast differentiation. Pretreatment of BMSCs with neutralizing antibodies against TNF?, but not IL-1?, blocked the RANKL suppressive effects on Osx and Runx2 expression. Conclusions: 1) HFD contributes to bone loss by increasing bone resorption, as demonstrated previously, and by suppressing bone formation via RANKL-mediated activation of IL-1? and TNF? signaling, as shown here. 2) Future confirmation of this finding in humans could lead to the development of therapies to alleviate HFD-induced bone loss.

Prediabetes is associated with lower trabecular bone score (TBS): Comparison of TBS according to the prediabetes phenotype *Yong Jun Choi[1], Kyounghwa Ha[1], Dae Jung Kim[1], Yoon-Sok Chung[1]. [1]Ajou University School of Medicine, Republic of Korea

Objective: Diabetes mellitus (DM) is known to be associated with a lower trabecular bone score (TBS) and an increased risk of fracture. However, little is known regarding whether it is associated with poor bone results in pre-diabetic individuals. Despite the fact that both IFG and IGT are characterized by insulin resistance and ?-cell dysfunction, the metabolic abnormalities are quite distinct between the two disorders. Impaired fasting glucose (IFG) was marked by dysfunctional insulin secretion and decreased hepatic insulin sensitivity. In contrast, impaired glucose tolerance (IGT) was related with decreased whole-body insulin sensitivity, followed by a decline in ?-cell function. We examined if TBS differed depending on the prediabetes phenotype. Methods: This was a cross-sectional analysis of baseline data collected from 30- to 64-year-old participants in the Study of the Cardiovascular and Metabolic Diseases Etiology Research Center (CMERC) Cohort Study. A whole-body dual-energy X-ray absorptiometry (DXA) scan and an oral glucose tolerance test were performed. Excluding those with diabetes, liver cirrhosis, chronic kidney disease, or cancer, as well as those on osteoporosis drugs, steroids, or thyroid hormones, or who had ever received hormone replacement treatment, we enrolled 3,276 individuals. Subjects were classified as having normal glucose tolerance (NGT), isolated IFG, isolated IGT, or combined IFG and IGT (IFG+IGT). Statistical analyses were conducted by dividing into three groups (male, premenopausal women and postmenopausal women). Results: Males with isolated IGT exhibited a lower TBS after adjusting for age, weight, vitamin D, Hba1c, cigarette smoking, and alcohol intake (1.466 vs. 1.494, P=0.040). However, statistical significance disappeared when visceral fat was additionally adjusted for. In premenopausal women, patients with isolated IFG had a lower TBS than those with NGT (1.493 vs. 1.513, P=0.044), and statistical significance was preserved even after visceral fat was further adjusted. There were no significant differences in TBS among groups of postmenopausal women. Conclusion: Similar to diabetics, prediabetics have decreased TBS levels compared to NGT people. However, there were gender disparities in the association between TBS and prediabetes. Insulin resistance with visceral fat may have a greater impact on TBS in men, but disruption in insulin secretion may have a greater impact on TBS in premenopausal women.

Yiqi Huayu Formula up-regulates type H vessel formation and promotes fracture healing in ovariectomized mice *Kanghui Sun[1], Xiaohui Hu[1], Liqiang Guo[1], Ziyu Huang[1], Yongjian Zhao[1], Dongfeng Zhao[1], Yongjun Wang[1], Bing Shu[2]. [1]Longhua Hospital, Shanghai University of TCM, China, [2], China

Objective: to observe the regulatory effect of Yiqi Huayu Recipe, the basic Chinese compound formula commonly used for bone repair, on H type vessels formation during fracture healing in ovariectomized mice. Methods: 3-month-old C57BL/6 female mice were randomly divided into sham group, model group, and Yiqi Huayu group. The mice in the model group and the Yiqi Huayu group underwent bilateral ovariectomy. Eight weeks after the surgery, all the mice underwent transverse fractures of the left tibias. On the same day after the fracture, the mice were given Yiqi Huayu Formula or physiological saline for gastric perfusion once a day. Results: Micro-CT and histological staining results showed that on the 28th day after fracture, the callus in the sham group and the Yiqi Huayu group basically completed remodeling, while the callus in the model group was still in the shaping stage. The maximum loading force of the healing tibias in the Yiqi Huayu group was significantly higher than that in the model group. The results of flow cytometry and immunofluorescence staining showed that on the 3rd day after fracture, the proportion of type H vascular endothelial cells in the total endothelial cells in the fracture area of the sham group began to increase until the peak was reached on the 7th day. The proportion in the model group increased on the 5th day after fracture, and the proportion of cells at each time point was significantly lower than that of the sham group. The proportion in the Yiqi Huayu group began to increase on the 3rd day after fracture, earlier than that in the model group. Compared with the model group, the Yiqi Huayu Formula significantly increased the production of type H vascular endothelial cells on the 3rd and 5th days after fracture. Conclusion: Yiqi Huayu Formula can improve the formation of type H blood vessels in early stage of fracture healing in ovariectomized mice, which may be partial mechanism of promoting fracture healing in ovariectomized mice.

Polycaprolactone and Hydroxyapatite Bioprinting without Using Solvents *Trenton Campos[3], Andy Liu[3], Dean Wertz[3], Carlos Mendez Cruz[3], Chet Friday[3], Michael Hast[3], Rashad Madi[3], Chamith Rajapakse[3]. [3]University of Pennsylvania, United States, [3]University of Pennsylvania, Puerto Rico, [3]University of Pennsylvania,

Introduction: Our goal was to develop a bioink using Polycaprolactone (PCL) and Hydroxyapatite (HA) without using harmful solvents for 3D bioprinting bone grafts. Current methods are cytotoxic and expensive as they dissolve the PCL and HA using solvents such as chloroform to make the bioink sufficiently uniform and viscous for extrusion printing. Methods: Molecular weight 45,000 g PCL pellets and 10 ? m HA powder were used. Dry PCL:HA mixtures were created using varying weight ratios of PCL to HA ranging from 90:10 to 65:35. Compositions were varied at 5% increments. Prior to printing, each mixture was melted in the extruder nozzle and mixed thoroughly to ensure proper dispersion of the HA. The pneumatic extruder nozzle was then placed into the bioprinter. For each composition, four sets of cuboids were printed with varied infill distances (3 and 5 mm) and geometries (grid and triangle) (Figure 1). For each set, two 10 x 10 x 5 mm3 cuboids were printed. Print speed, pressure (PSI), print surface, and layer height were held constant. The increased concentrations of HA resulted in increased bioink viscosity and the temperature was increased to standardize viscosity. After printing, the scaffolds were tested for stiffness (in N/mm2) using a universal test frame. Results: Compositions of PCL:HA were uniformly printed up to ratios of 65:35. There was no decrease in cuboid quality as the HA concentration was increased; however, a small reduction in thickness was noted, likely due to the increased viscosity of the prints. Compression testing showed that print compositions of 75:25 had the greatest stiffness, with a mean maximal load of 2470 N/mm2. Due to a small sample size, further testing is necessary. ANOVA testing showed that there were no statistically significant differences between the stiffness of different infill geometries and lengths (Figure 1). Discussion: Melting dry mixtures of PCL with subsequent HA mixing is a better alternative than the utilization of chloroform to dissolve the PCL. Higher compositions of HA can be obtained and the method is much safer, cost-effective, and less time-consuming. Furthermore, remelting the PCl allows printing to be quickly resumed in contrast to having to redissolve the PCL in chloroform with the alternative method. Further research is needed to investigate the osteogenic and mechanical properties of the newly created PCL:HA prints and determine the optimal concentration for different orthopaedic applications.

Stress-stimulated glucocorticoid release affects diverse biological processes, including pregnancy and childbirth. The controversy surrounding effects of OXT on stress prompted us to investigate its actions on adrenal cortical function in mice. RNAscope and immunohistochemistry provided unequivocal evidence for abundant OXT receptor (OXTR) expression in the adrenal cortex, predominantly in zona fasciculata and zona reticularis. Female mice displayed higher adrenal cortical Oxtr expression, more than a range of other tissues under

study. Oxtr expression was also detected in the adenohypophysis solely in female mice, while both male and female mice expressed Oxtr in the pars intermedia of the hypophysis. Aging impressively attenuated Oxtr expression in female mice in both the adrenal gland and adenohypophysis. For loss-of-function studies, we generated tissue-specific Star-CreERT2/Oxtrfl/fl mice in which the Oxtr was deleted from steroidogenic tissues, namely adrenals and ovaries. Deletion was confirmed by RNAscope and immunohistochemistry. We found no difference in serum corticosterone between tamoxifen-induced and uninduced mice; however, the elevation of serum corticosterone upon ACTH stimulation or after four weeks of stress was attenuated in tamoxifen-induced mice. Bulk RNAseq of adrenals from tamoxifen-induced mice revealed the downregulation of key steroidogenic genes, namely Cyp17a1, Hsd3b3, Hsd17b2, Cyp3a41b, and Serpina6 (a corticosteroid-binding globulin). In gain-of-function studies, a single OXT injection led to a rise of serum ACTH in tamoxifen-induced mice, which was greater in magnitude than uninduced controls. However, after five days of OXT injections, corticosterone levels became elevated, whereas ACTH levels declined to baseline. This suggests that OXT acts directly on OXTRs on corticotropes to initiate a stress-like response, with a negative feedback loop that inhibits further ACTH secretion. Of note is that male mice did not display any difference between tamoxifen-induced and uninduced groups, consistent with their low hypophyseal Oxtr expression. In all, we describe a novel gender-specific two-pronged circuit through which OXT may precisely regulates the production of corticosterone from the adrenal cortex. In the first arm, OXT directly stimulates ACTH secretion through adenohypophysis OXTRs. In the second arm, OXT prevents excessive stress-induced adrenal stimulation by downregulating steroidogenic genes. Our discovery lays the foundation for the emergence of new physiology that may relate to a fundamental role for oxytocin in the stress response during procreation, notably, when levels are elevated during pregnancy and lactation.

Maternal But Not Offspring Ablation of Cyp27b1 Impairs Neonatal Growth and Skeletal Development in Mice *Sarah A. Hartery[1,] Beth J. Kirby[1,] Emma C. Walker[2,] Alexandre S. Maekawa[1,] David Bennin[1,] René St-Arnaud[3,] Natalie Sims[4,] Christopher S. Kovacs[1.] [1]Memorial University of Newfoundland, Canada. [2]St. Vincent's Institute of Medical Research and University of Melbourne, Australia. [3]McGill University and Shriners Hospital for Children-Canada, Canada. [4]St. Vincent's Institute of Medical Research and University of Melbourne , Australia

Ablation of Cyp27b1 eliminates calcitriol but does not disturb fetal mineral homeostasis or skeletal development. However, independent of fetal genotypes, maternal loss of Cyp27b1 causes higher fetal serum calcium, lower FGF23, lower renal excretion of calcium and phosphorus, and higher 25OHD and its metabolites, compared to fetuses of WT dams. Since milk from Cyp27b1 null dams has 30% less calcium than WT, we hypothesized that maternal loss of Cyp27b1 would continue to impair offspring skeletal development after birth.Cyp27b1 null and sister WT dams were kept on a calcium-, phosphate-, and lactose-enriched diet and mated to bear only Cyp27b1+/- pups. 48 hours after birth, all pups were cross-fostered to dams that delivered concurrently. Neonatal groups included pups of WT dams fostered by null (WT?null), null fostered by WT (null?WT), and two controls (WT?WT and null?null). Dams and pups were harvested on day 21. Neonatal BMC was measured by PIXImus DXA. Hindlimbs were analyzed by microCT. Neonatal bodies were reduced to ash; mineral content was determined by atomic absorption spectroscopy. Hormones and serum and urine minerals were measured. Maternal behavior was monitored by video surveillance. Milk was collected at day 10 to analyze nutritional content.In comparing all pups nursed by null to all pups nursed by WT, pups nursed by nulls had ~20% lower weight (7.56+/-2.1[SD] vs 9.52+/-1.8 g), BMC (0.15+/-0.04vs 0.19+/-0.04 g), and ash weight (0.26+/-0.07 vs 0.31+/-0.05 g) (all p<0.001). Ash calcium did not differ (30.0+/-2.3 vs 29.1+/-1.1 mg/g, p=NS). Adjustment for body weight accounted for the lower BMC and ash weight. Serum calcium, phosphorus, calcitriol, PTH, FGF23, IGF-I, and urine calcium, phosphorus, and magnesium, did not differ across the four groups. MicroCT showed neonates nursed by null dams had lower cortical thickness, mean polar moment of inertia, cortical area, trabecular bone volume and number (all p<0.01), but femur length was unaffected. No differences were seen in dam behaviors; milk collection and analysis is in progress.In summary, pups nursed by Cyp27b1 nulls, regardless of birth mother, had lower body weight, BMC, ash weight, and impaired bone microstructure, but no changes in systemic mineral homeostasis or total skeletal mineral content, as compared to pups nursed by WT.In conclusion, maternal loss of calcitriol impairs postnatal cortical bone growth and development of the trabecular network, independent of offspring genotype.

SUN-171

A long non-coding RNA as a direct vitamin D target transcribed from the anti-sense strand of the human HSD17B2 locus. *Yoshiaki Kanemoto[1,] Akira Hayakawa[2,] Takahiro Sawada[1,] Jinichi Mori[3,] Tomohiro Kurokawa[3,] Shigeaki Kato[1.] [1]Iryo Sosei University, Japan. [2]Research Institute of Innovative Medicine, Japan. [3]Fukushima Medical University, Japan

The known target mRNA genes of VDR are unlikely to account for all of the wide variety of VD actions, and non-coding RNAs(ncRNAs) appear to facilitate physiological and pathological VD actions. However coding regions for ncRNAs are in general not conserved among species. Given the fact that VD analogues are beneficial for bone health, we used in silico and transcriptomic approaches in human cell lines to search for human non-coding RNAs transcriptionally regulated by VD directly, and showed that VD-inducible enhancer RNAs supporting ligand-induced transcription of a VD target mRNA gene in keratinocyte cell line (HaCaT) (Kanemoto et al., JNSV, 67:424-, 2021).In this study, four long non-coding RNAs (lncRNAs), but no microRNAs, were found as VD direct targets by transcriptomic approaches using the VDR KO HaCaT cells, Consensus VDRE -related elements in the promoters of all of the four lncRNA coding regions are present, with documented VDR associations with these regions in ChIP atlas data base. One of these lncRNAs (designated as AS-HSD17B2) is transcribed from the anti-sense strand of the HSD17B2 locus, and the VDR-associated element in the AS-HSD17B2 promoter served as an efficient VDRE in a reporter assay. VD-regulated expression of HSD17B2 was seen also in LNCaP cells. Thus, AS-HSD17B2 represents a direct lncRNA target of VD (Kanemoto et al., Biosci. Res., 42:BSR20220321, 2022), suggesting that cell-type specific non-coding RNAs mediate tissue specific actions of VD. Thus, AS-HSD17B2 is a VDR target lncRNA, that is supposed to mediate VD action in human keratinocytes and prostate cancer. As chromatin environment facilitating production of ncRNAs is distinct among cell types, currently we are assessing if AS-HSD17B2 as well as the other three lncRNAs express osteosarcoma cell lines (U2OS and SaOS2). Transcriptome approach used in our report has also applied to identify VD/VDR target ncRNAs specifically expressed in osteosarcoma cells.

Comparative Analysis of PTH (1-34), PTHrP (1-36), and Abaloparatide Effects on Murine Osteoblast Transcriptome *ZHIMING HE[4,] Michael Mosca[2,] Florante Ricarte[3,] CAROLE LE HENAFF[4,] Nicola Partridge[5.] [4]New York University, . [2]NYU Langone Medical Center, . [3]Department of Molecular Pathobilogy, New York University college of Dentistry, United States. [4]New York University, United States. [5]New York University College of Dentistry, United States

Teriparatide (PTH (1-34)) and its analogs, PTHrP (1-36) and abaloparatide (ABL) have been used for the treatment of osteoporosis, but their efficacy over long-term use is significantly limited. Our laboratory has shown that PTH (1-34), PTHrP (1-36), and ABL exert time and dose-dependent differential responses in osteoblasts, leading us to hypothesize that they may also differentially modulate the osteoblast transcriptome. Here, we treated mouse calvarial osteoblasts with 1 nM of the 3 peptides for 4 h and analyzed the resulting RNA-Seq data. Gene-set enrichment analysis revealed that PTH (1-34) regulated 367 genes, including 194 unique genes; PTHrP (1-36) regulated 117 genes, including 15 unique genes; and ABL regulated 179 genes, including 20 unique genes. There were 74 genes shared exclusively between PTH (1-34) and ABL, 16 genes shared exclusively between PTH (1-34) and PTHrP (1-36), and 83 genes shared among all 3 peptides. The significant differences in the expression of various genes from the 3 peptides indicate gene ontology specific differences, including differences in Wnt signaling, cAMP-mediated signaling, bone mineralization, morphogenesis of a branching structure in biological processes; cytokine receptor/binding activity,

ligand-activated transcription factor activity, cAMP phosphodiesterase activity in molecular functions. The 3 peptides increased Vdr, Cited1 and Pde10a mRNAs in a differential fashion similar to Rankl expression. These findings were confirmed via qRT-PCR with additional cultured samples. mRNA abundance of other genes of interest based on gene/pathway analyses, including Wnt4, Wnt7, Wnt11, Pde10a, Sfrp4, Dkk1, Kcnk10, Hdac4, Epha3, Tcf7, Crem, Fzd5, Pp2r2a, and Dvl3 were also examined; some genes were stimulated similarly by all 3 peptides; others were not. Finally, experiments with siRNA knockdowns of SIK1/2/3 and CRTC1/2/3 in PTH (1-34) treated cells showed that some of these genes are regulated by SIKs and CRTCs (Vdr, Wnt4), while others are not. Although many studies have examined PTH signaling in the osteoblast/osteocyte, ours is the first to examine the global effects of these peptides on the osteoblast transcriptome. Further delineation of which signaling events are attributable to PTH (1-34), PTHrP (1-36) and ABL exclusively and which are shared among all 3 will help improve our understanding of the effects these peptides have on the osteoblast and lead to the refinement of PTH-derived treatments for osteoporosis.

Cell surface pathways of PTH and PTH1 receptor *Jonathan Pacheco[1], Karina Pena[1], Sofya Savransky[1], Gerald hammond[1], John Janetzko[2], Jean-Pierre Vilardaga[1]. [1]University of Pittsburgh, United States. [2]Stanford University, United States

The formation of PTH-receptor-arrestin is an important function of the cell membrane to transmit hormone actions. However, the paths and plasma membrane mechanism used by PTH, its receptor and ?-arrestins (?arr) to assemble the ternary signaling complex are not known. We are tackling this fundamental mechanism by using single-molecule and biochemical analyses. Here, fluorescent moieties were attached in the PTH type 1 receptor (PTH1R), PTH, ?arr, and clathrin. By recording dual-color single-molecule imaging at the plasma membrane of live cells, we found that PTH1R exhibits a near-Brownian diffusion, whereas the hormone is randomly confined at the cell surface. The PTH-PTH1R-?arr complex assembles through three sequential steps: 1) receptor collisions with the stationary ligand confined in pre-existing clathrin clusters, 2) phosphoinositide (PIP3) dependent recruitment and conformational change of ?arr molecules in clathrin clusters, and 3) ?arr collision with the ligand-bound receptor. These results provide insight into the cell surface pathway by which a PTH1R-arr complex is assembled and unveil a novel role of PIP3 in regulating PTH1R signaling. They also indicate that the central tenet that formation of cell surface ligand-receptor-arrestin complexes originates exclusively from direct interactions of ligand and ?arr with receptors must be revised.

Absent LH Signaling Rescues the Anxiety Phenotype in Aging Female Mice *Steven Sims[1], Orly Barak[1], Vitaly Ryu[1], Sari Miyashita[1], Hasni Kannangara[1], Funda Korkmaz[1], Soleil Wizman[1], Anne Macdonald[1], Anisa Gumerova[1], Ki Goosens[1], Mone Zaidi[1], Tony Yuen[1], Daria Lizneva[1], Tal Frolinger[1]. [1]Icahn School of Medicine at Mount Sinai, United States

Clinical studies and experimental data together support a role for pituitary gonadotropins, including luteinizing hormone (LH), otherwise considered solely as a fertility hormones, in age-related cognitive decline. Furthermore, rising levels of LH in post-menopausal women have been implicated in the high prevalence of mood disorders. This study was designed to examine the effect of deficient LH signaling, using the global Lhcgr-/- mouse, on both cognitive and emotional behavior in 12-month-old mice. For this, we established and validated a battery of five tests, including Dark-Light Box (DLB), Y-Maze Spontaneous Alternation, Novel Object Recognition (NOR) and contextual and cued Fear Conditioning (FCT) tests. We found that 12-month-old female mice display a prominent anxiety phenotype on DLB and FCT. This phenotype was not seen in female Lhcgr-/- mice, indicating full phenotypic rescue. Furthermore, there was no effect of depleting LHCGRs on recognition memory or working spatial memory on NOR and Y-maze testing, respectively, in 12-month-old mice, notwithstanding the absence of a basal phenotype in wild type littermates. The latter data do not exclude an effect of LH on cognition documented in previous studies. Finally, male mice and 3-month-old male and female mice did not consistently display deficits on any test. The data collectively document, for the first time, that loss of LH signaling reverses age-related emotional disturbances, a prelude to future targeted therapies that block LH action.

EXT608 for the Treatment of Hypoparathyroidism: Phase 1 Trial Design and Results *Laura Hales PhD[1], Kate Didio MBA[1], Leon Shi PhD[2], Daniel Hall PhD[1], Poul Strange MD PhD[2], Daniel Dickerson MD PhD FAAFP[3], Tarik Soliman PhD[1]. [1]Extend Biosciences, United States. [2]IMD, United States. [3]ICON plc, United States

Extend Biosciences is developing EXT608, a long-acting parathyroid hormone (PTH 1-34)-based therapy designed to replace the physiological effects of PTH with significantly less frequent dosing and improved bioavailability. EXT608 was developed using the company's D-VITylation® platform, which harnesses the biology of vitamin D and the reversible binding properties of the serum-circulating vitamin D binding protein. By utilizing this natural pathway, D-VITylation prevents a vitamin D-conjugated therapeutic from renal clearance, thereby significantly extending its half-life. Bioactivity is not compromised and as such, EXT608 is fully active as-is at the PTH receptor.A double-blind, randomized, placebo-controlled Phase 1 trial involving 24 healthy participants (3:1 active:placebo) across 6 cohorts was conducted with EXT608. The primary endpoint was to characterize the safety and tolerability profile of escalating dose levels of EXT608 when administered to healthy adult subjects as a single injection by 1) observing the incidence, nature, and severity of adverse events (AEs) and withdrawals due to treatment emergent AEs, 2) noting the frequency and severity of post-dose change from baseline in hematology, serum chemistries, urinalysis, electrocardiogram, vital signs, and physical examination findings, and 3) determining the percentage of subjects with injection or infusion site reactions. Secondary endpoints included 1) determining plasma pharmacokinetic parameters, and 2) assessing the pharmacodynamic profile by measuring post-dose change from baseline in serum chemistries and urinalysis. The results show that EXT608 was safe and well tolerated, with no serious adverse events reported. It also shows a dose dependent increase in serum calcium. A prolonged suppression of endogenous parathyroid hormone was also observed, as anticipated. The pharmacokinetic analysis suggests that EXT608 can be effective when dosed once-weekly. The data provide a strong rationale to proceed to the next stage of clinical development and also offer valuable guidance for selecting a starting dose in the Phase 2 trial.

Eldecalcitol Inhibits Bone Turnover And Increases Bone Mass Via Acting On BMSCs *An Xiong[1], Yingying Gu[1], Haibo Li[1], Miaoying Lin[1], Ran Zhang[2], Daniel. D Bikle[3], Zhongjian Xie[1]. [1]National Clinical Research Center for Metabolic Diseases, Hunan Provincial Key Laboratory of Metabolic Bone Diseases, and Department of Metabolism and Endocrinology, The Second Xiangya Hospital of Central South University, China. [2]Department of Medical Laboratory, Hunan Normal University School of Medicine, China. [3] Veterans Affairs Medical Center, University of California San Francisco, United States

Aims: Eldecalcitol (ELD) is one of the active vitamin D analogues that has been shown to inhibit bone turnover and increase bone mass, but the underlying mechanism is unclear. Bone marrow mesenchymal stem cells (BMSCs) are the progenitor cells of osteoblasts, and we hypothesized that ELD increases bone mass by acting on BMSCs. To test the hypothesis, we investigated the effect of ELD on bone mass and osteogenic differentiation of BMSCs in the vitamin D receptor (VDR) conditional knockout mice (cKO).Methods: VDR cKO mice were generated by breeding floxed-VDR mice and PRX1-Cre mice. Floxed-VDR mice were used as a control. Both control and cKO mice were treated with ELD at a dose of 50 ng/kg or vehicle for 4 weeks. Micro-CT was performed to examine the bone mass and bone microstructure morphometrics of femur. Calcein double-labeling, ALP, and TRAP staining were used to examine the bone mineral apposition rate (MAR), the number of osteoblasts, and osteoclasts, respectively. Primary BMSCs were isolated from 8 week-old wild-type mice and cultured in osteogenic medium. Cells were treated with ELD at concentrations of 10-10, 10-9, or 10-8 M for 7 days. The expression of RANK in BMSCs was reduced by siRNA and cells were then treated with 10-9 M ELD for 72 hours. The mRNA and protein expression levels of RANK, RANKL and osteogenic differentiation markers including ALP and RUNX2 were examined by quantitative PCR and western blotting.Results: Micro-CT showed that control mice treated with ELD displayed increases in bone mass, bone volume percentage, and bone trabecular number and decreases in bone trabecular separation compared to vehicle group; Calcein double-labeling, ALP, and TRAP staining showed that control mice treated with ELD displayed reduced MAR, number of positive osteoblasts and osteoclasts compared to the vehicle group. The effects from above were blocked by BMSC conditional knockout of VDR. ELD inhibited expressions of differentiation markers including ALP and RUNX2 and RANKL and promoted RANK expression in a dose-dependent manner in BMSCs. The inhibitory effect of ELD on the expression of ALP, RUNX2 and RANKL was blocked by down-regulation of RANK in BMSCs.Conclusion: ELD inhibits bone turnover and increases bone mass via acting on VDR of BMSCs. ELD suppresses osteogenic differentiation and RANKL expression possibly via promoting RANK expression in BMSCs.

Very low dose ACTH treatment increases bone formation in rabbits in vivo and stimulates bone formation gene expression in human osteoblast cultures in vitro *Irina Tourkova[1], Quitterie Larrouture[2], Harry Blair[1]. [1]Pittsburgh VA Medical Center and University of Pittsburgh, United States. [2]University of Pittsburgh, United States

We show that very low dose (0.6 ?g/kg rabbit mass) ACTH daily treatment for five weeks increases bone formation in rabbits. We evaluated adrenocorticotropic hormone (ACTH), cortisol, glucose, and vascular endothelial growth factor (VEGF) in rabbit blood serum as a function of ACTH dose as a single subcutaneous injection. We found that injecting 0.6 ?g per kg rabbit mass did not measurably increase ACTH over no added ACTH in serum in an ELISA over several hours, and had essentially no effect on cortisol (Figure, left panel) or glucose. Actual added serum ACTH is estimated as 1 to 10 pM but is too low to be measured by available rabbit assays (serum half life of ACTH is ~20 minutes). Following this, we evaluated the effect on bone formation after five weeks of treatment with 0.6 ?g/kg rabbit mass ACTH daily by micro-computed tomography (microCT) analysis and fluorescent tetracycline double labeling with one week interval. We revealed that 0.6 µg/kg/day of ACTH treatment increases trabecular bone structure (percent bone volume, bone surface density, and trabecular sickness) in the femoral head on micro-computed tomography images and significantly increased labeling of bone formation with tetracycline estimated by quantification of labeled area, p = 0.0056, n = 3 (Figure, right panel). In vitro, ACTH in as low concentrations as low as 10-12 M increased expression of Collagen type 1 and RunX2 in human osteoblasts differentiating for three weeks on polyethylene terephthalate (PET) membrane inserts with 0.4 micron perforations, which optimizes mineral transport into the matrix and acid transport. VEGF mRNA and the VEGFA receptor FLT-1 and FLK-1 mRNAs were also upregulated at 1 pM ACTH. In related work, mRNA expression of mitochondrial complex 1 (NDUFA5, NDUFS2, NDUFB1, NDUFB6) members, playing key role in energy production, were upregulated by 10-12 M ACTH treatment. An ELISA for complex 1 activity showed similar effects, with maximum activity at 10-9 M but 70% of maximal activity at 10-12 M ACTH.Collectively, our results indicate that very low dose ACTH treatment increases bone formation in vivo and in vitro, and upregulates energy production in human osteoblasts.

Bone Mineral Density in Low Dose vs. Very Low-Dose Estrogen OC users *Taylor Demasi[1], Jordan Beall[1], Michelle Tsang[1], Kristine Giltvedt[1], Mark Kern[2], Shirin Hooshmand[1]. [1]San Diego State University, United States. [2],

Oral contraceptives (OCs) may negatively impact bone health in young females by suppressing the amount of endogenous estrogen in the body. OCs with very low estrogen doses (<=20 mcg EE) may produce more negative consequences than those of low estrogen doses (>20 mcg EE.) The purpose of this study was to compare bone mineral density (BMD) in different doses of OCs.Fifty-six women, aged 18-25 y, who were either using very low (n=22) or low-dose (n=34) OCs were assessed. Participants were required to have taken their OC for at least one year before joining the study. Anthropometrics, physical activity, reproductive health, and habitual calcium and vitamin D intake were evaluated. DXA scans were performed for total body, right and left femur, AP spine, and non-dominant arm.The groups did not differ significantly for height, weight, BMI, age at menarche, average number of days between menstruation, age at first OC use, duration of OC use in years, or calcium and vitamin D intake. Very low dose users were significantly older (+1 yr; p=0.016) and consumed alcohol for a longer duration (+1.2 yr; p=0.021). No differences for BMD were detected for any of the measured bone sites regardless of controlling for age and duration of alcohol use. Although other studies have demonstrated that individuals on very low-dose OCs may have lower BMD compared to low-dose users, these results of this small sample do not agree.

A DNA Tetrahedron-based Stem Cell Enrichment Technology in Osteoarthritis Targeted Therapeutic Research *xingyu Chen[1], Taoran Tian[2], wumeng Yin[3], Yunfeng Lin[2]. [1]State Key Laboratory of Oral Diseases, West China Hospital of Stomatology, Sichuan University, , China. [2]Sichuan University, China. [3]State Key Laboratory of Oral Diseases, West China Hospital of Stomatology, Sichuan University, , China

Stem cell therapy is a promising strategy for OA treatment, but reliable sources of stem cells still need to be discovered. In previous studies, we found that the DNA tetrahedron (TDN) exhibits precise editability and a predictable structure. The tetrahedral structure of TDN provides a topological basis for chemical modification, which can be used to combine with stem cell targeting aptamers to construct a stem cell enrichment system for OA treatment. In this study, TDN was initially created and then modified with 1-3 DNA aptamers targeting stem cells, extending from 1-3 vertices (denoted as T1, T2, and T3). The gel electrophoresis results showed that the T1, T2, and T3 synthesis yields were over 80%. Subsequently, the synthesized DNA materials were incubated with positive and negative cells. It was found that the T3 structure had the highest binding efficiency to the membrane of positive BMSC cells, significantly higher than that of randomly arranged monovalent adapters. Following that, biotin was added to the fourth vertex of the T3 structure to achieve effective magnetic separation. Alternatively, thiols were added to the fourth vertex of the T3 structure to covalently connect the inflammatory protein targeting adapter (DTA64) to hyaluronic acid (HA), and the in vitro cell recruitment impact of DTA64-HA-T3 was validated using transwell assays. Finally, a rat OA ACLT model was created, and tissue sections obtained one week later revealed co-localization of the T3 structure and the DTA64 inflammatory protein adaptor, supporting the HA-T3 structure's in vivo targeting site retention. In the future, MSC-specific CD29 and CD44 labeling will be used to confirm the successful stem cell recruitment to the inflamed location in the rat joint cavity. Additionally, micro-CT imaging will assess the degree of joint regeneration and repair. These findings suggest that the TDN framework's topological structure can effectively manage the number and spatial distance of the targeting DNA sequences connected to it, considerably boosting targeting efficiency and specificity. Moreover, the DTA64-HA-T3 stem cell enrichment method shows strong inflammatory targeting in the rat OA joint cavity and good specificity for collecting stem cells in vitro. These findings offer a novel therapeutic option for clinical osteoarthritis and contribute to a significant advancement in treating rat OA.

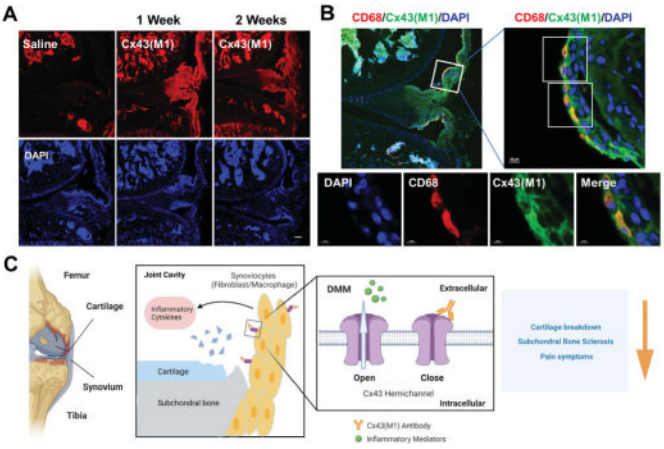
Targeting Synovial Connexin Hemichannels Ameliorates Osteoarthritis Progression *Rui Hua[1], Yi Tian[1], Manuel A. Riquelme[1], Xuewei Wang[1], Liang Ma[1], Sumin Gu[1], Jean X. Jiang[1]. [1]UT Health San Antonio, United States

Osteoarthritis (OA) is a degenerative joint disease characterized by progressive articular cartilage deterioration, subchondral bone sclerosis, and synovial inflammation. The gap junction protein connexin 43 (Cx43), a key regulator of musculoskeletal homeostasis, is overexpressed in cartilage and synovium of OA patients. However, the contributions of Cx43 to OA pathogenesis remains largely elusive. Cx43 forms hemichannels (HCs) and mediate the release of small molecules (< 1.2 KDa), such as ATP and PGE2, into the extracellular environment. To determine whether deletion of Cx43 in joint tissue could ameliorate OA symptoms, we adopted adeno-associated virus (AAV) mediated Cre expression in Cx43 fl/fl mice using a destabilization of the medial meniscus (DMM) surgery induced OA model. Intra-articular injection of AAV-Cre decreased Cx43 level, with a higher efficiency in the synovium (p=0.001) than in the cartilage (p=0.065). MicroCT analysis showed reductions in subchondral BV/TV, Tb.Th, and BMD with AAV-Cre mediated Cx43 deletion. Moreover,

reduced Cx43 expression mitigated OA-related pain behaviors evaluated by von Frey and open-field tests. To further investigate the role of Cx43 HCs in OA progression, a monoclonal Cx43(M1) antibody that specifically blocks Cx43 HCs was developed. In vivo Evens blue dye uptake assay showed that DMM increased HCs opening by 2 folds, which was inhibited by the antibody. Impeded Cx43 HCs by the antibody improved cartilage structure as quantified by OARSI score, decreased degree of synovitis, along with reduction of MMP13 and Collagen X levels. Subchondral sclerosis and OA pain symptoms were also alleviated in the Cx43 antibody treated group. Remarkably, in vivo distribution of this antibody is predominantly in synovium, including macrophages and fibroblasts, with sustained presence for over 2 weeks. In addition, OA induced increase of M1 macrophages, as indicated by the iNOS/CD68 double positive cells, was attenuated after antibody treatment. In vitro study using mouse macrophages or human synovial fibroblasts demonstrated the inhibition of LPS or IL1?-induced HCs opening and inflammatory genes expression (COX2, ADAMTS 4/5, and MMP3/13) by Cx43 HC-blocking antibody. In summary, our results highlight the crucial role of Cx43 and HCs in regulating pro-inflammatory mediators under OA conditions. Targeting synovial Cx43 HCs, thus, is a potential therapeutic strategy to mitigate the inflammatory environment during OA progression.



Targeting synovial connexin 43 hemichannel as a potential therapeutic target of OA

(A) *In vivo* distribution of Cx43(M1) antibody shows accumulation primarily in the synovium with sustained presence for over 2 weeks. **(B)** Colocalization of Cx43(M1) antibody with macrophage marker CD68. **(C)** Schematic illustration showing the administration of Cx43(M1) antibody blocks hemichannel opening and release of inflammatory cytokines, thus improving joint structure, subchondral bone sclerosis and pain symptoms.

Therapeutic effect according to the dose of 17?-estradiol in the knee and temporomandibular joints of ovariectomized rats *Hoon Joo YANG[1], Ji Hye OH[2], Jiwon DO[1]. [1]Department of Oral and Maxillofacial Surgery, School of Dentistry, Seoul National University, Seoul, Korea, Republic of Korea. [2]Dental Research Institute, Seoul National University, Seoul, Korea, Republic of Korea

Osteoarthritis (OA) is a degenerative joint disease that mainly affects middle-aged and elderly people. However, progressive condylar resorption (PCR) similar to temporomandibular joint (TMJ) OA has been reported to occur mainly in young women in their teens and twenties. And the patients with PCR have been reported to have low serum 17?-estradiol (E2) levels, even though they are not menopausal. Deterioration of bone cell function and osteoporotic changes due to a decrease in E2 levels may occur systemically, but OA was not observed in the knee joint (KJ) of PCR patients. The purpose of this study was to compare the changes in TMJ with the changes in KJ according to E2 concentration and to evaluate the applicability of estrogen therapy for PCR treatment. In female Sprague-Dawley rats, ovariectomy (OVX) was performed to induce estrogen deficiency, and E2 of 0, 10, 50, and 100 ?g / 100g doses was administered intraperitoneally daily for 4 weeks after 8 weeks of OVX. Bony changes and cartilage inflammation in the TMJ and KJ were evaluated using micro-CT, real-time PCR, histochemical staining, and immunohistochemical staining. OVX induced osteoporotic changes in the TMJ condyle, which were most evident in the posterior area. On the other hand, in the KJ, osteoporotic changes were found in the tibial neck, but no significant changes were shown in the tibial condyle. BMD and BV of the TMJ condyle and tibial neck were significantly increased by all doses of E2, and it was confirmed that 100 ?g / 100g of E2 caused more osteosclerotic changes than in the sham group. The tibial condyle showed no changes with E2 supplementation. In TMJ cartilage, inflammatory changes were observed to increase when 50 and 100 ?g / 100g of E2 were applied, but in KJ cartilage, no significant inflammatory changes were observed in OVX and E2 supplemented groups. Therefore, the study suggests that low dose (10 ?g / 100g) of E2 may have a therapeutic effect on the osteoporotic changes of TMJ, with minimal harmful effects such as inflammation and side effects on other joints. This finding may be useful in developing optimal treatment concentrations of E2 for TMJOA caused by estrogen deficiency in young female patients.

High Repetition Low Force Task Performance Causes Entheseal Damage and Palmar Muscle Fibrosis in Older Rats with Work-Related Overuse Injuries *Parth R Patel[1], Alex Lambi[2], Steven Popoff[3], Mary Barbe[4]. [1]Center for Translational Medicine, Lewis Katz School of Medicine of Temple University, United States. [2]University of New Mexico, . [3]Lewis Katz School of Medicine at Temple University, United States. [4]Temple University School of Medicine, United States

To better understand the progression of overuse injury, it is crucial to study morphological changes occurring at the tissue level that correlate with functional changes. Using an established rat model of work-related overuse injury, we have shown greater grip strength declines in mature (14-18 mo) rats than young adult rats (3-9 mo) performing the same moderate task, declines that correlated with forearm muscle inflammatory cytokine levels. We sought here to determine if forepaw musculoskeletal changes were also contributors. Experiments were approved by the Institutional Animal Care and Use Committee. Following a 4-week training period, mature female rats went on to perform a high repetition (4 reaches/min), low force (0.29N) task for 9-12wks, 2hrs/day, 3days/wk (HRLF; n=14). Results were compared to age-matched resting Controls (n=11) and animals that trained and then rested for 12wks (Tr+Rest; n=10). We analyzed histologic data from forepaw muscles (thenar, hypothenar, and deep intrinsic) and wrist/forepaw entheses. Muscle fibrosis (percent muscle area with collagen) in combined forepaw muscles was significantly increased in HRLF rats, compared to Tr+Rest and Control rats ($p<0.05$). Forepaw entheses were graded binarily with 1 indicating present each for five domains: attachment site holes, cartilage islands, tidemark fissuring, void space, and vascular invasion. HRLF rats showed significant entheseal changes indicative of damage in the summed average of the five domains, compared to Tr+Rest and Control rats ($p<0.05$ each). Individual domain analysis revealed more attachment site holes and tidemark changes in HRLF forepaw entheses. Using percent change in grip strength from naive to post-task, we performed a Spearman's correlation analysis between percent muscle collagen and change in grip strength and found a moderate inverse relationship ($r=-0.52$, $p<0.05$). We have previously shown that mature rats performing HRLF tasks also develop osteopenia in distal forelimb bones. We extend those results to report here the presence of forepaw histopathology: forepaw muscle fibrosis and entheseal damage following prolonged work-related overuse in very mature rats. The increased muscle collagen content correlated with declines in grip strength. These findings contribute to the understanding of local effects of repetitive overuse injuries in upper extremity tissues and have significant clinical relevance as human females report more work-related overuse.

Sex differences in knee joint pain in relation to joint pathology *Tyler Vesey[1], Peter Caradonna[1], Nic Sian[1], Madison Mueth[1], Victoria Eaton[1], Kathleen Becker[1], Tamara King[1]. [1]University of New England, United States

Osteoarthritis (OA) pain is heterogeneous and mechanisms underlying different OA pain phenotypes are not understood. Many patients report pain during joint use that dissipates with joint rest, defined as mid-stage OA pain. Some patients report development of persistent ongoing pain that is resistant to recommended treatment, defined herein as advanced OA pain. We examined the hypotheses that mid-stage and advanced OA pain have different levels of joint pathology and pathological sprouting of sensory fibers.Male and female C57bl/6 mice received knee joint injections (10 ?l) of different concentrations of monosodium iodoacetate (MIA) to induce mid-stage or advanced OA pain phenotypes. Knee joint pain was assessed 14 days post-injection using analysis of shifts in weight away from the MIA treated knee joint to determine weight bearing associated pain. Conditioned place preference to pain relief was used to determine development of persistent pain characteristic of advanced OA pain in patients. Mid-stage OA pain was defined as weight asymmetry in the absence of persistent pain, advanced OA pain was defined as weight asymmetry and persistent knee joint pain. Following behavioral analysis (D15), knee joint tissue was collected and processed for histology to assess cartilage loss and joint pathology (toluidine blue, H&E) and alterations in innervation of the tibialis anterior muscle using the pan-neuronal marker beta tubulin 3 (BT3). All behavioral testing and image analyses were performed by an experimenter blinded to the treatment and sex of the joint images.Females developed advanced OA pain phenotype at a 5-fold lower dose compared to males. Analysis of joint pathology demonstrates that males and females both demonstrate concentration dependent signs of knee joint OA including cartilage loss, synovitis, and bone remodeling. However, females developed advanced OA pain with less joint pathology compared to males. Analysis of fiber density using BT3 revealed concentration dependent changes in joint innervation corresponding to changes in pain phenotype in males. Studies are ongoing to examine

whether females with advanced OA pain show increased joint innervation with less joint damage compared to males.

Phlpp1 and Articular Cartilage Tissue Quality in Osteoarthritis *KATHERINE ARNOLD[1], SAMANTHA WEAVER[3], Jennifer Westendorf[3], Elizabeth Zars[4], Daniel Tschumperlin[5]. [1], , [3]Mayo Clinic, United States, [3]Mayo Clinic, , [4]Department of Orthopedic Surgery, Mayo Clinic, United States, [5]Department of Physiology and Biomedical Engineering, Mayo Clinic, United States

Osteoarthritis (OA) is a chronic and common disease affecting 1 in 4 adults. OA is characterized by articular cartilage deterioration, osteophytes, and other joint changes. Deficient mechanical and structural qualities (e.g., stiffness) are detected in cartilage weeks before histologic signs of OA are apparent in animal models of post-traumatic OA. Atomic Force Microscopy (AFM) micro-indentation is frequently used to measure the stiffness (via the elastic modulus E) of articular cartilage with high spatial resolution and force sensitivity. Phlpp1 is a protein phosphatase that slows chondrocyte proliferation and regeneration, and its genetic deletion in mice results in thicker articular cartilage and higher chondrocyte density. We previously showed that Phlpp1 deletion can protect from injury-induced cartilage degradation; however, we do not know if Phlpp1 deletion affects the mechanical properties of cartilage after injury. As cartilage is a primarily structural tissue, maintenance of the structural integrity is essential for function. Baseline experiments showed no difference in the elastic modulus of healthy adult articular cartilage either with sex or genotype in wildtype (WT) and Phlpp1-/- mice. Next, we examined cartilage tissue quality in WT and Phlpp1-/- mice at 2, 6, and 12 weeks post-DMM (destabilization of the medial meniscus) surgery, which induces post-traumatic OA. Male WT mice showed decreased activity at 12 weeks post-injury, and more histological signs of cartilage damage. Phlpp1-/- mice did not exhibit changes in behavior or cartilage damage. With AFM, we detected significant decreases in elastic modulus of medial condylar cartilage at 6 weeks, local to the injury in WT but not Phlpp1-/- mice. By 12 weeks, cartilage modulus had decreased from 2MPa to ~1MPa on both medial and lateral sides in WT mice. The Phlpp1-/- mice showed only a 25% decrease in modulus at 12 weeks post-DMM. Similar results were seen in female mice, with WT mice showing significant decreases in elastic modulus at 12 weeks post-DMM compared to Phlpp1-/- mice. Histologic scores of the female tibiae were less severe than the males, with no significant changes in score at any timepoint. This study illustrates the differences between DMM on male and female mice, specifically related to the mechanical changes that take place with PTOA and validates Phlpp1 inhibition as a potential therapeutic strategy for articular cartilage preservation after injury.

Differential osseous gene expression in swim-trained anosteocytic and osteocytic teleost fish *JOSEPHINE T. TAUER[1], Tobias Thiele[2], Catherine Julien[3], Lior Ofer[4], Paul Zaslansky[5], Ron Shahar[4], Bettina Willie[6]. [1]Shriners Hospital, Canada, [2]Julius Wolff Institute, Charité - Universitätsmedizin Berlin, Germany, [3]Shriners Hospital for Children-Canada, Montreal; Faculty of Dental Medicine and Oral Health Sciences, McGill University, Canada, [4]Koret School of Veterinary Medicine, The Robert H. Smith Faculty of Agriculture, Food and Environmental Sciences, The Hebrew University of Jerusalem, Israel, [5]Department of Operative and Preventive Dentistry, Charité - Universitätsmedizin Berlin, Germany, [6]McGill University, Canada

Introduction: Osteocytes are considered mechanosensory bone cells that regulate bone (re)modeling in response to mechanical stimuli. Surprisingly, evolutionarily advanced fish lack osteocytes but still exhibit bone formation in response to loading. While there is knowledge of the molecular mechanisms controlling mammalian mechanoadaptation, fish data is lacking. Thus, we aimed to identify molecular mechanisms in anosteocytic bones (ricefish; RF) and osteocytic bones (zebrafish; ZF) after loading.Methods: Fish were trained by swimming for 5 minutes against a current and sacrificed after 1-, 8-, or 24 hours (h). Vertebrae were analyzed using RNA sequencing and compared to non-trained controls (n=6 fish/genotype).Results: At each time point, 26,099 and 21,129 gene reads for ZF and RF have been identified, respectively. After filtering non-skeletal genes (Ayturk et al. JBMR, 2013:28), 14, 54, and 977 differentially expressed genes (DEGs) have been identified in ZF, and 353, 284, and 763 DEGs in RF at 1h, 8h, and 24h, respectively. Enrichment analysis showed in ZF that upregulated DEGs were related to protein translation at 1h, and to DNA transcription and cell cycle processes at 24h, while downregulated DEGs were linked to muscle function, circadian rhythm, and metabolic processes at 24h. In RF, upregulated DEGs were associated with ion channel activity related to metabolic processes in muscle at 8 and 24h, while downregulated DEGs were related to cytoskeletal organization at 8h. Osteoblast differentiation associated enriched DEGs were identified in ZF at 8 and 24 h, but not in RF. Applying a customized ‘osseous analysis panel’ identified 87 ‘osseous DEGs’ (oDEGs) in ZF and 71 in RF, primarily upregulated in ZF and downregulated in RF. Only one upregulated oDEG was identified in RF, myocilin, a regulator of osteoblast differentiation, at 1h and 24h post-training.Conclusion: Zebrafish benefited from numerous osteocytes for bone formation in response to mechanical stimuli, while ricefish exhibited delayed skeletal modeling after swim training. It’s speculated that in anosteocytic bone, non-osteocytic cells, such as bone lining osteoblasts, chondrocytes, and chordoblasts, sense and respond to mechanical load differently over time (Ofer et al. PLoS Biol, 2019:17). Our findings challenge the current paradigm of osteocytes as the exclusive regulators of bone remodeling and suggest the existence of multivariate feedback networks involved in bone remodeling.

SUN-189

Cortical Bone Responds to a Single Mechanical Loading Bout in Mice Administered a Bioenergetic Drug *Omar Dervisevic[1], Justin Samuel[2], J Fritton[3]. [1]Department of Biomedical Engineering, City College of New York, United States, [2]CUNY School of Medicine, City College of New York, United States, [3]CCNY, United States

Locally enhancing bone’s response to load-bearing exercise would benefit prevention of osteoporosis. The mechanical threshold for initiating a local response requires large impact loads. Potentially lowering the threshold is our aim by administering the bioenergetic drug, fructose 1,6 bisphosphate (FBP) immediately prior to application of the non-invasive, well-controlled, mouse tibia, cyclic compression model. In an IACUC approved study, 12-wk-old B6 female mice were administered either 12.5% FBP or vehicle control via i.p. injection (pH buffered, sterile saline). 30 minutes later in vivo mechanical loading of the left (L) tibia was completed in 5 minutes (4 Hz, 1200 cycles) under isoflurane anesthesia via ElectroForce LM1. Load groups included, 2N, 6N and 10N (n=10/group). The right (R) tibia serves as paired, intra-animal control for comparison. Double labels (calcein and xylenol orange) were i.p. injected after loading and 3 d before sacrifice that was 10 d post loading bout. Tibias were then scanned by ?CT (Skyscan 1272, 10?m) for structural analyses. Alignment by registration of each scanned tibia with contralateral (Bruker), followed by comparison by % length (Matlab) in all groups revealed relative differences, [L-R]/R at $p<0.05$. In the proximal tibial area that normally responds with formation at 10N (25% of length), greater (8%) cross-sectional max moments of inertia (MOI) were found in loaded limbs from both FBP and vehicle-control, i.e., greater cortical bone geometry to resist bending. In contrast, only the FBP-treated group demonstrated such greater (7%) MOI after the single bout of 6N loading, suggesting a reduced mechanical threshold for response at the time of loading. No significant MOI differences due to 2N loading were found in either FBP or vehicle-control. Other studies in mice suggest bioenergetic drugs that, like FBP, inhibit glycolysis, may also enhance mechanosensitivity. While bioenergetics hold promise in combination with mechanical loading, separating direct effects on the in vivo target-cell population, osteocytes, from indirect effects secondary to increased energy availability is a limitation of studies that utilize multiple drug treatments over weeks. There are also limitations to this current study. However, the pursuit of such a strategy (bioenergetic drug administration only at the time of a single mechanical loading bout) holds the potential to demonstrate mechanism(s).

An in vitro Orbital Flow Model to Study Mechanical Loading Effects on Osteoblasts *Chandrasekhar Kesavan[1], Subburaman Mohan[1]. [1]Jerry L. Pettis Memorial VA Medical Center, United States

Mechanical loading is an important physiological regulator of bone-forming osteoblast function. The fluid flow induced by mechanical loading in vivo is dynamic and oscillatory. Several models have been developed to mimic the in vivo oscillatory flow in cultured osteoblasts, including the commonly employed fluid flow chamber and oscillatory flow apparatus, which requires a complex setup. Since the flow induced by an orbital shaker is also known to produce shear stress and oscillatory flow, we evaluated the utility of this model for studies on mechanical loading effects in osteoblasts. We isolated osteoblasts from adult (12-16-week-old) C57BL/6J mice and plated 10,000 cells on the peripheral edge of the 6-well plate where the flow effect is expected to be high. The plates were subjected to flow at 0.7-, 1.4-, and 3.3-frequency (Hz)/sec for 30- and 50-minutes, respectively, using the orbital shaker in serum-free differentiation medium. The shear stress produced by 0.7-, 1.4- and 3.3-Hz on cells were 1.1-, 3.3-, and 37- dynes/cm2, respectively, as calculated using the formula ?max=??p(2?f)3. The ALP activity measured 72 hours after orbital flow showed a significant increase at 0.7 & 1.4 but not at 3.3 Hz compared to static controls. In addition to ALP activity, we also found significantly increased (25%) osteoblast proliferation at 0.7Hz compared to static controls. Furthermore, expression levels of bone formation markers, Osf2, Hif1a, Vegf, and Cox2, were significantly increased (1.5 to 3-fold, $p<0.05$) in cells subjected to 0.7 Hz flow compared to non-loaded cells. We also evaluated the effect of orbital flow on key signaling pathways (mTOR, JNK, WNT) known to mediate mechanical loading effects on osteoblasts. We found that blocking mTOR and WNT signaling with inhibitors significantly reduced (20-30%) orbital flow-induced ALP activity compared to cells treated with vehicle. By contrast, JNK signal inhibition did not significantly affect flow-induced osteoblast differentiation. In conclusion, our findings demonstrate that the orbital shaker model is an excellent inexpensive model to study mechanical loading effects on osteoblasts in vitro.

Mechanical Memory Effected Chondrogenesis of Mesenchymal Stem Cells by Using Microgroove-Patterned Hydrogel *Siying Wu[1], Yang Liu[1], Ziyan Wang[1], Hongzhi Liu[1], Chao Liu[1]. [1]Southern University of Science and Technology, China

Purpose: Mechanical stimulation is a critical factor in cartilage regeneration, as it directly activates mechano-sensing molecules and influences stem cell migration and differentiation. Recent studies have also shown that mechanical memory and dosing can impact stem cell fate, with cells retaining a "memory" of their past physical environments. Based on this understanding, we hypothesize that pre-culturing mesenchymal stem cells (MSCs) on microgroove patterned hydrogels with varying widths could generate different elastic moduli and preserve the resulting mechanical memory in the cells, ultimately affecting chondrogenesis.Method: We obtained MSCs from C57BL/6 mice and expanded them in culture dishes for two passages (P0-P1). Subsequently, in passages 2 and 3, the cells were cultured on gelatin hydrogels with flattening and microgroove patterns of varying widths (20-200 um) to achieve pre-mechanical dosing. We then examined the cell mechanics by performing the immune staining of vinculin, phalloidin, and YAP. To study the chondrogenic ability of pre-mechanically dosed MSCs, we carried out staining, western blotting, and qPCR in vitro. Additionally, we validated the chondrogenic repair ability of those MSCs in an articular cartilage full-thickness defect mouse model in vivo (Figure 1a).Result: The microgroove patterned gel substrate has been shown to guide MSC alignment and promote significant cell elongation, resulting in a higher elastic modulus compared to a flat substrate (as depicted in Figure 1b, c). Further investigation will be conducted on the cell mechanics, chondrogenic ability, and the mechanism of pre-mechanically dosed MSCs.Conclusion: This study aims to uncover the underlying mechanism of mechanical memory in MSCs and its impact on chondrogenesis, potentially providing valuable insights into the plasticity of stem cells during development.

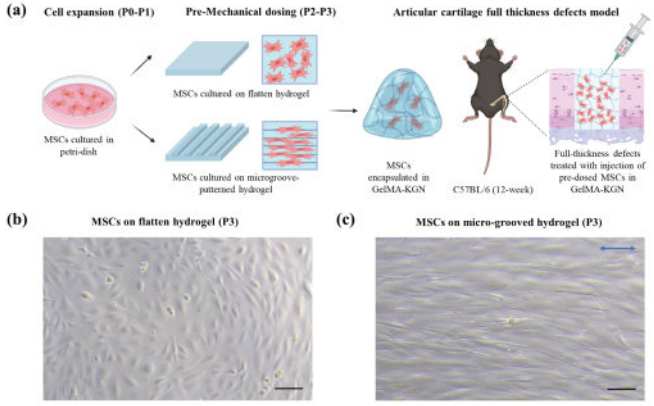

Figure 1. (a) Experimental design: MSCs were expanded from P0 to P1 on a culture dish, pre-mechanically dosed with flatten or microgroove-patterned hydrogel substrates, and then their chondrogenic repair ability was evaluated in a mouse model of articular cartilage full thickness defect. MSCs were cultured on (b) flatten, and (c) microgroove-patterned hydrogel with a width of 20 μm. The blue double-headed arrow indicates the direction of the grooves. Scale bar = 100 μm.

Engineered Bone Analog Models Designed for Testing on the International Space Station *MAXIMILIEN DELEON[1], Sean Howard[2], Omor Khan[2], Anamaria Zavala[2], Angela Kubik[3], Chess Necessary[4], Kendall Nelson[4], Sam Perry[4], Isabel Moore[4], Zach Jacobs[4], Paul Gamble[4], Aykut Satici[2], Mary Farach-Carson[5], Elizabeth Blaber[3], Gunes Uzer[2], Danielle Wu[6]. [1], [2]Boise State University, United States. [3]Rensselaer Polytechnic Institute, United States. [4]Space Tango, United States. [5]University of Texas Health Science Center at Houston, School of Dentistry, United States. [6]University of Texas Health Science Center, United States

Purpose: Bone homeostasis is influenced by mechanical forces that alter anabolic responses and bone quantity/quality. Astronauts lose bone during prolonged spaceflight. To investigate Low Intensity Vibration (LIV) as an effective countermeasure to bone loss in microgravity, we developed 3D Bone Marrow Analogs (BMAs) to be maintained in hardware aboard the International Space Station (ISS). We engineered a perfusable 'Cube Well' system containing 16 BMAs housed within a CubeLab™ containing fluidic and electromechanical systems. We expect LIV to increase anabolic activity of Bone Marrow Stromal Cells (BMSCs) in BMAs to be tested in ground controls and on the ISS.Methods: The CubeLab™ will support automated media changes and preservation steps of BMAs on the ISS [4 Cube Wells/CubeLab™; 2 CubeLabs™: +LIV and -LIV] and matched ground controls. Osteogenic factors are delivered with StemBeads® for controlled release. BMAs consist of hydrogel-encapsulated BMSCs and 3D printed resin scaffolds mimicking trabecular lattices of young (25% BV/TV) or old (15% BV/TV) bone [bone volume/total volume]. To perform experiments within the volume and power limitations on the ISS, CubeLab™ performance is rigorously tested before launch. Studies include testing diffusion rates in and out of the BMAs to assess media change frequency, determining optimal time for solution changes for fixation to assess protein and RNA levels as an index of anabolic activity, assessing extent of mineralization, and verifying full-system integration and automation of fluidic and LIV systems.Results: The Cube Wells satisfied some/most mission success criteria in pre-launch testing. A subpopulation of BMSCs in BMAs attached to the lattice and produced matrix; others remained in a bulk hydrogel. Media changes every 2 days maintain cellularity. Small solutes in BMA exchanged by diffusion by 60 mins. An observed increase in cellularity and collagen production in 25% (young) but not 13% (old) BMAs comparing LIV treated and static groups may be due to the proximity of BMSCs to scaffold surfaces and variable strains. Exposure to LIV (1g, 100 Hz) increased collagen production. Mineralization is being assessed after the addition of osteogenic factors via StemBeads®.Conclusions: BMAs in the Cube Well/CubeLab™ system provide a valuable platform for testing use of LIV as an effective countermeasure to prevent/slow bone loss during microgravity/space flight.

Osteocytic Connexin 43 Deficiency Attenuates HLS-Induced Epiphyseal Bone Loss in Female, but not Male, C57Bl/6J Mice *Gabriel Hoppock[1], Evan Buettmann[2], Jolene Windle[2], Henry Donahue[2. 1]. [2]Virginia Commonwealth University, United States

Preceding research has shown that gap junction communication and mechanical stimulation, or lack thereof, influence bone development and remodeling, however, the mechanisms by which this occurs remain unclear. Our lab and others have shown deficiency of connexin 43 (Cx43), bone's predominant gap junction protein, in early osteoblasts/osteocytes protects against unloading-induced bone loss in mice.1,2 It is unclear, however, if this protection is due to Cx43 deficiency in osteoblasts or osteocytes, the latter being the most abundant and primary mechanosensory bone cell. To address this, we used a Cx43-deficient mouse targeting later osteoblasts/osteocytes to test the hypothesis that osteocyte-specific Cx43 deficiency protects against hindlimb suspension (HLS)-induced bone loss.All animal procedures were approved by the VCU IACUC. At 6 months of age, male and female osteocyte-specific Cx43 deficient mice (Cx43?OCY) and their wildtype littermates (WT) with C57Bl/6J backgrounds underwent HLS or normal ambulation (control) for 21 days (n=8-11 per group). MicroCT scans were taken on days 1 and 22 and images the left femur was analyzed. Separate 2-way ANOVAs with Bonferroni's post-hoc tests were used to assess female and male mice for significant effects of genotype and HLS ($p<0.05$).At baseline Cx43?OCY mice had decreased diaphyseal cortical bone compared to WT (Figure 1A). In the epiphysis and metaphysis, male mice showed an increase in bone volume due to Cx43 deficiency, but female mice did not. The basal differences between WT and Cx43?OCY mice show osteocytic Cx43 plays a sexually dimorphic role in postnatal bone volume. After 21 days of HLS, significant effects of HLS were found in all female and male epiphyseal and metaphyseal changes as well as in Ct.Ar/T.Ar (Figure 1B). Interestingly, osteocyte-specific Cx43 deficiency protected against HLS-induced decreases in epiphyseal BV/TV in female but not male mice. Cx43 deficiency did not affect HLS-induced decreases in metaphyseal or cortical bone in either male or female mice. These results suggest osteocytic Cx43 deficiency causes increased trabecular and decreased cortical bone basally. The data also show osteocytic Cx43 deficiency protects against HLS-induced epiphyseal bone loss in female mice whereas early osteoblast Cx43 deficiency likely also protects against metaphyseal bone loss, as shown previously by our lab.21. Grimston et al. J Bone Miner Res. 2011. 2. Lloyd et al. J Bone Miner Res 2012.

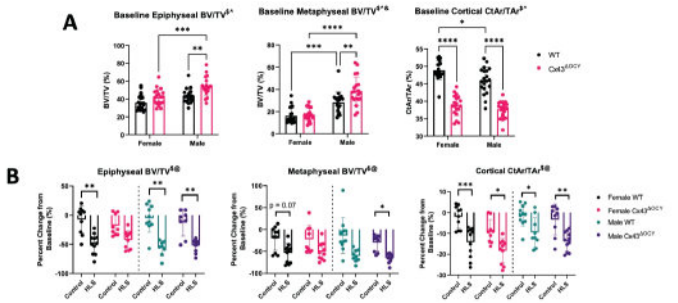

Figure 1. A. Osteocyte specific Cx43 deficiency led to increased trabecular bone but decreased cortical bone fraction. Renal Osteodystrophy Precision Medicine Project *Valentin David[1], Hartmut Malluche[2], Isidro Salusky[3], Thomas Nickolas[4]. [1]Northwestern University, Feinberg School of Medicine, United States, [2]University of Kentucky Medical Center, United States, [3]University of California, Los Angeles School of Medicine, United States, [4]Columbia University, United States

Renal osteodystrophy (ROD) is a complex disorder of bone metabolism that affects virtually all patients with chronic kidney disease (CKD). ROD is associated with adverse clinical outcomes including bone loss, mineralization and turnover abnormalities, skeletal deformities, fractures, cardiovascular events, and death. Despite current therapies, fracture incidence is 2- to 100-fold higher in adults with compared to those without CKD. Limited knowledge of ROD pathogenesis impedes development of therapeutics aimed at reducing morbidity and mortality of CKD patients.Bone-tissue based information obtained from patients with ROD that includes altered epigenome and transcriptome as a function of disease progression is missing and highly contributes to this critical knowledge gap. We aim to obtain robust and necessary preliminary data assessing the variability and demonstrating the rigor and reliability of single nuclei sequencing in bone by simultaneous profiling of the transcriptome (using 3' gene expression) and epigenome (using ATACseq) to deepen our understanding of how genes are expressed and regulated across different cells and kidney disease stages. Our long-term goal is to create the fundamental infrastructure to facilitate high-impact novel hypothesis-driven clinical and translational research in ROD by building a large-scale data and tissue biorepository integrating clinical, bone quality, transcriptomic and epigenomic data along with stored urine, blood, and bone samples.We have started the collection of bone biopsies from adults with CKD 3-5D and a reference population of kidney-healthy adults with age-related osteoporosis. Our studies will determine the changes in osseous transcriptome and epigenome of patients with ROD vs osteoporosis at the cellular level using single nuclei RNA and ATAC sequencing. Finally, based on these results we will develop a user pipeline with an interactive open access web-based interface.This resource will provide the underpinnings for future research endeavors leading to the elucidation of the pathogenesis of ROD across the spectrum of CKD including dialysis. These results will contribute to our efforts to redefine our understanding of ROD pathogenesis and pathophysiology and the development of disease targeted prevention strategies.

Background:Osteoporosis is a common condition in postmenopausal women, which increases the risk offractures and morbidity. Previous studies have shown that osteoporosis results from anunbalanced pattern of bone remodeling, with higher bone resorption than the formation.Osteoporosis affects approximately 200 million people worldwide. In India, there are around50 million individuals with osteoporosis or low bone mass. Approximately 40% of post-menopausal women and 20% of men suffer fractures each year. In post-menopausal women,osteoporosis is related to increased age and decreased levels of estrogen. Several studies haveshown that microRNAs contribute to the pathogenesis of post menopausal osteoporosis viadysregulated bone homeostasis. In this study, the expression of miR335-5p was investigated inpostmenopausal osteoporosis (PMO) and its potential role in regulating bone metabolism.Aim:To investigate the expression of miR335-5p in PMO and its potential role in regulating bone metabolism.Materials and Methods:Serum samples were collected from postmenopausal women with osteoporosis (n=50) and healthy controls (n=30), and miR335-5p expression was measured using real-time PCR. In silico analysis was performed to identify potential target genes of miR335-5p, using several databases such as miRwalk, Target Scan, miRDB, and miRpath.Results:The results showed that miR335-5p was significantly upregulated in the serum samples of postmenopausal women with osteoporosis compared to controls. Further in silico analysis identified SERPINB1 as a direct target of miR335-5p. SERPINB1 protein is a known inhibitor of neutrophil-derived proteinases, which protects tissues from damage at inflammatory sites. SERPINB1 has also been shown to inhibit osteoclast formation, which may contribute to its protective effect on bone metabolism. Other important genes involved in bone metabolism i.e., RUNX2, SOX4, and MAPK1 are also targets of miR335-5p. The protein tissue atlas showed that SERPINB1 is highly expressed in bone marrow, which supports its potential role in regulating bone metabolism and the pathogenesis of osteoporosis.Conclusion:Targeting miR335-5p and increasing the expression of SERPINB1 protein may be a promising approach to treat PMO. This could be achieved by suppressing osteoclast formation, which may protect tissues from damage at inflammatory sites and thus reduce the risk of fractures and morbidity. Further studies are required to validate these findings and explore the dual-potential therapeutic implications of targeting miR335-5p and SERPINB1 in osteoporosis.

Title: miR335-5p and its potential target SERPINB1 as a regulator of bone metabolism in postmenopausal osteoporosis (PMO)

Authors: **Simran Kaur**, Vandana Dhiman, Nainesh Joshi, Raman Kumar, Mani, Ravi Pratap Barnwal, Gurpal Singh, Sudhaker Rao, Sanjay Kumar Bhadada*

Background:

Osteoporosis is a common condition in postmenopausal women, which increases the risk of fractures and morbidity. Previous studies have shown that osteoporosis results from an unbalanced pattern of bone remodeling, with higher bone resorption than the formation. Osteoporosis affects approximately 200 million people worldwide. In India, there are around 50 million individuals with osteoporosis or low bone mass. Approximately 40% of post-menopausal women and 20% of men suffer fractures each year. In postmenopausal women, osteoporosis is related to increased age and decreased levels of estrogen. Several studies have shown that microRNAs contribute to the pathogenesis of post-menopausal osteoporosis via dysregulated bone homeostasis. In this study, the expression of miR335-5p was investigated in postmenopausal osteoporosis (PMO) and its potential role in regulating bone metabolism.

Aim:

To investigate the expression of miR335-5p in PMO and its potential role in regulating bone metabolism.

Materials and Methods:

Serum samples were collected from postmenopausal women with osteoporosis (n=50) and healthy controls (n=30), and miR335-5p expression was measured using real-time PCR. In silico analysis was performed to identify potential target genes of miR335-5p, using several databases such as miRwalk, Target Scan, miRDB, and miRpath.

Results:

The results showed that miR335-5p was significantly upregulated in the serum samples of postmenopausal women with osteoporosis compared to controls. Further in silico analysis identified SERPINB1 as a direct target of miR335-5p. SERPINB1 protein is a known inhibitor of neutrophil-derived proteinases, which protects tissues from damage at inflammatory sites. SERPINB1 has also been shown to inhibit osteoclast formation, which may contribute to its protective effect on bone metabolism. Other important genes involved in bone metabolism i.e., RUNX2, SOX4, and MAPK1 are also targets of miR335-5p. The protein tissue atlas showed that SERPINB1 is highly expressed in bone marrow, which supports its potential role in regulating bone metabolism and the pathogenesis of osteoporosis.

Conclusion:

Targeting miR335-5p and increasing the expression of SERPINB1 protein may be a promising approach to treat PMO. This could be achieved by suppressing osteoclast formation, which may protect tissues from damage at inflammatory sites and thus reduce the risk of fractures and morbidity. Further studies are required to validate these findings and explore the dual-potential therapeutic implications of targeting miR335-5p and SERPINB1 in osteoporosis.

The Dp1Yey Down Syndrome Mouse Model Exhibits Deficits in Microarchitecture and Strength of the Femur and Lumbar Vertebrae *Joshua Lamantia[1], Kourtney Sloan[2], Randall Roper[3]. [1]Indiana University-Purdue University-Indianapolis, United States, [2], , [3]Indiana University-Purdue University Indianapolis, United States

Down syndrome (DS) is a genetic disorder that affects about 1 in 800 live births, resulting from the triplication of human chromosome 21 (Hsa21). People with DS have distinctive craniofacial features, cognitive deficiencies, and skeletal deficits which can lead to increased risk of fractures, particularly in the femoral neck and lumbar spine. While previous research has studied femoral bone deficits in DS mouse models, little is known about the vertebrae, which are also affected in humans with DS. Understanding when and what kind of skeletal deficits occur is crucial for identifying potential treatments. We used the Dp1Yey DS mouse model, which has all genes triplicated on mouse chromosome 16 that are orthologous to Hsa21. This model accounts for roughly 63% of the genes triplicated in Hsa21 and displays long bone deficits in male but not female mice at 12 weeks based on previous studies. Using micro-computed tomography and 3-point bending, the trabecular and cortical regions of the femur and the 4th lumbar (L4) vertebra in male and female Dp1Yey mice and wildtype controls were quantified at 6 weeks of age. Male Dp1Yey mice exhibited deficits in trabecular and cortical regions of the femur, while female Dp1Yey mice solely presented cortical deficits. Both male and female Dp1Yey mice suffered from significantly lower bone mineral density (BMD) in the L4 vertebra and deficits in trabecular thickness and bone volume fraction (BV/TV). Skeletal abnormalities have been reported in Ts65Dn and Dp1Tyb DS mouse models which show similar but not identical findings. Ts65Dn mice exhibit trabecular and cortical deficits at both 6 and 16 weeks of age in both males and females. In Dp1Tyb mice, trabecular deficits were seen only in males at both 6 and 16 weeks while female Dp1Tyb as compared to control mice did not show any significant trabecular deficits. Cortical deficits, however, were seen in both males and females at these ages. Dp1Tyb and Dp1Yey are thought to be genetically similar, and while the overall conclusions of these mouse models

are consistent, there are small differences in the data that may be attributed to environmental and procedural differences. Our findings suggest that skeletal deficits associated with DS occur early in development, are sex-dependent, and that early treatment may be necessary to improve associated deficits in DS.

A Blueprint to Archive µCT and Bone Histomorphometry Data *Peter Maye[1], Dong-Guk Shin[2], Thomas Andersen[3], Je-Yong Choi[4], David Rowe[5]. [1]UCONN Health, United States. [2]University of Connecticut, United States. [3]University of Southern Denmark, Denmark. [4]School of Medicine, Kyungpook National University, Republic of Korea. [5]University of Connecticut Health Center, United States

The mechanistic regulation of the skeletal system is extremely complex involving a multitude of local and systemic processes that far surpasses what any one individual can conceive. Rapid developments in machine learning approaches bring new possibilities to integrate accumulated knowledge that will advance research and therapeutic development. However, few databases exist that are exclusively dedicated to documenting the skeletal function of genes that would enable machine-learning approaches.The skeletal phenotyping of rodent animal models via µCT and bone histomorphometry analysis yields significant insight into how bone tissue is regulated. However, no central resource exists for storing and accessing datasets generated by skeletal phenotyping. The archiving of bone histomorphometry datasets contributed by generations of investigators over time will undoubtedly become a highly valued resource for a broad user base and will empower systems biology approaches to solve complex mechanisms of skeletal regulation that previously were not possible.Here we detail our resource development plan to build a biomedical data repository to archive and share bone histomorphometry data. This plan has three major objectives: 1) Develop a data ingestion method that is comprehensive in regard to experimental manipulation (genetic, treatment, or combination) for rodent animal models and includes the associated experimental metadata. Maintains high data quality standards by requiring peer-review publication of work and for unpublished studies provides a path to publication in a special issue associated with the repository hosted by the journal Bone. 2) Develop a database system that is scalable and designed for enhanced accessibility and query processing with the proper privacy, backup, and security measures in place. 3) Develop a web portal that exemplifies FAIR principles and includes efforts to harmonize data for interstudy comparisons.This resource will be further supported by an external advisory committee that will establish policies of data governance and the use of scientific emissaries based in North America, Europe, and Asia that will establish a global network of working groups that will be involved in the preliminary testing of applications at progressive stages of development prior to launch. We welcome interested investigators to attend our poster session or contact us (https://bonebase.lab.uconn.edu/contact_us/) to become part of a working group.

SUN-198

The Ts66Yah mouse model displays cortical skeletal deficits associated with Down syndrome *Kourtney Sloan[1], Laurent Meijer[2], Joseph Wallace[3], Yann Herault[4], Randall Roper[5]. [1]Department of Biology, Indiana University-Purdue University, United States. [2]Perha Pharmaceuticals, France. [3]Indiana University Purdue University Indianapolis (IUPUI), United States. [4]Department of Translational Medicine and Neurogenetics, Université de Strasbourg, Centre National de la Recherche Scientifique, Institut National de la Santé et de la Recherche Médicale, Institut de Génétique et de Biologie Moléculaire et Cellulaire, France. [5]Indiana University-Purdue University Indianapolis, United States

Down syndrome (DS) is a genetic condition that alters bone development and maintenance. Many mouse models of DS have been developed but not all have had the appendicular skeleton characterized. The Ts66Yah mouse model has been developed to contain ~50% of human chromosome 21 (Hsa21) orthologous genes on a freely segregating third chromosome, without triplicating the ~35 protein-coding, non-orthologous genes found in Ts65Dn mice, heretofore the most analyzed DS mouse model. Structural properties of male and female 6-, 9-, and 16-week-old Ts66Yah femurs were analyzed using micro-computed tomography (µCT) to understand phenotypes between bone accrual and peak bone mass. Trabecular measurements revealed no genotypic effects compared to wildtype mice at 6 or 16 weeks, but there was a genotypic effect (P=0.048) in trabecular thickness (-5.6% of wildtype) at 9 weeks. There were cortical deficits, including total cross-sectional area (Tt.Ar,-9%), marrow area (Ma.Ar,-12%), periosteal perimeter (Ps.Pm,-4%), and endocortical perimeter (Ec.Pm,-6%), that showed genotypic effects at 6 weeks (P=0.005). At 9 weeks, Ma.Ar (-18.4%) and Ec.Pm (-8%) showed genotypic effects (P<=0.006). Additionally, cortical area fraction (BA/TA) had a genotypic effect (P<0.006) but was increased by 9%. At 16 weeks, there was interactions of genotype and sex (P<=0.02) where only male Ts66Yah mice as compared to wildtype mice showed deficits in Tt.Ar (-18%), Ma.Ar (-29%), Ps.Pm (-7.5%), and Ec.Pm (-16%) in posthoc analyses. Previous studies in Ts65Dn mice showed trabecular deficits in both sexes at 6 weeks and in male mice at 16 weeks, in addition to cortical deficits. These data suggest that trabecular deficits in Ts65Dn mice may be driven by non-orthologous trisomic genes. A potential drawback of the Ts66Yah model may be the lack of trabecular deficits at 6 and 16 weeks and cortical effects in female mice at 16 weeks. However, these results may indicate Hsa21 orthologous genes in Ts66Yah only impact cortical bone, and more trisomic genes are necessary to cause DS-related trabecular deficits. We are also investigating the effect of Dyrk1a, a trisomic gene in Ts65Dn, Ts66Yah, and humans with DS, by breeding Ts66Yah mice with Dyrk1a heterozygous mutant (Dyrk1a+/-) mice to normalize Dyrk1a copy number and treating Ts66Yah mice with a DYRK1A inhibitor and analyzing the resultant femurs. These results and further analyses will help understand the gene-phenotype relationship in DS skeletal deficits.

Comprehensive Characterization of the Ovariectomized Sheep Model of Postmenopausal Osteoporosis *Katie Bisazza[1], Brad Nelson[1], Katie Sikes[1], Jeremiah Easley[1]. [1]Colorado State University, United States

Ovariectomized (OVX) sheep are commonly used for osteoporosis research because they are comparable to humans in bone size and microarchitecture. However, the cellular pathways involved in bone turnover in ovine models of osteoporosis have not been fully elucidated. The objectives of our study were to comprehensively characterize the bone density, protein, and cellular changes in a long-term OVX-corticosteroid combination ovine model, as well as evaluate any clinical and systemic effects. Sixteen skeletally mature ewes were enrolled in the study (CSU IACUC #2060). Ten animals underwent OVX surgery and were administered a high-dosage regimen of corticosteroids. Six animals were used as healthy age-matched controls. In-life imaging and iliac crest bone biopsy collections were performed at baseline (prior to OVX), 3, 6, 9, and 12-months. Parametric data were assessed for statistical differences using a two-way ANOVA and an alpha value of 0.05 or less considered significant. The lumbar spine and tibia were scanned using dual-energy x-ray absorptiometry (DXA) to monitor bone mineral density (BMD). Lumbar spine and tibia BMD of OVX sheep was significantly lower than control animal BMD at 3 and 6-months, while lumbar spine BMD was also significantly lower than controls at 9 and 12-months (Fig. 1A-B). Blood collection and body weights were performed monthly to assess systemic health. Biopsies of the iliac crest were collected at each time point for micro-computed tomography (microCT) analysis to compare bone microarchitecture. Bone volume fraction (BV/TV) of OVX sheep was significantly lower than controls at 3 and 9-months (Fig. 1C). Trabecular number (Tb.N) was also decreased at 6-months (Fig. 1D). Samples were then processed for decalcified histology and stained for histomorphometry analysis. Small bone biopsies were flash frozen for LC/MS untargeted proteomic analysis to evaluate protein production and/or degradation in the bone. Proteomic and histomorphometry data processing is currently ongoing. Large animal preclinical models offer researchers the ability to compare bone changes in the same animals over time, allowing for a more comprehensive insight into the progression of postmenopausal and age-related bone loss. Understanding the cellular pathways involved in osteoporosis disease progression in the sheep model could aid in future cellular therapy research and lead to novel pathway targets for disease treatment in humans.

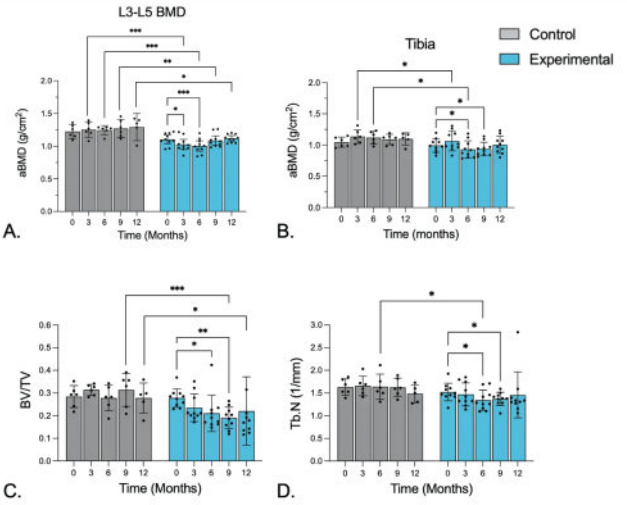

Figure 1. Comparison of bone parameters between OVX (osteoporotic) sheep and age-matched control sheep. *A)* Bone mineral density of the lumbar spine L3-L5 and *B)* the tibia using DXA imaging. *C)* MicroCT bone volume fraction and *D)* trabecular number of iliac crest biopsies. (*) indicates significance of p<0.05.

Gene expression profiles in fibroblast growth factor 23 (FGF23)-producing tumors provide new insights on diagnostics and therapeutic intervention.
*Sofya Gronskaia[1], Ruslan Devitiarov[2], Sergey Popov[1], Svetlana Rodionova[3], Yuriy Buklemishev[3], Liudmila Rozhinskaya[1], Oleg Gusev[2], Zhanna Belaya[1]. [1]Endocrinology Research Centre, Russian Federation. [2]Regulatory Genomics Research Center, Kazan Federal University, Russian Federation. [3]National Medical Research Center of Traumatology and Orthopedics named after. N.N. Priorov, Russian Federation

Background: Fibroblast growth factor 23 (FGF23)-producing tumors are histologically known as phosphaturic mesenchymal tumors (PMT). A PMT causes an oncogenic osteomalacia (OOM), which is associated with multiple fractures, severe pain, and muscle weakness.Aim: To analyze gene expression profiles of PMT versus control tissue.Methods: PMT and surrounding control tissue samples were obtained during tumor resection in 5 patients (Age 62 [45; 65], iFGF23 (ELISA Kit Biomedica BI-20700 -113 [50; 203] pg/ml (ref. range 14.8 [3.8;25.0]pg/ml), serum phosphorus 0.51 [0.4; 0.53]mM/L (ref. range 0.74-1.52 mM/l)). Based on histological verification we obtained 4 PMT samples (2 -mandibular bones, 1 - femur bone, 1 - metatarsal bone) and performed bulk RNA sequencing. We used Gene Ontology (GO) and the Kyoto Encyclopaedia of Genes and Genomes (KEGG). Results: A total of 976 genes were differently expressed between PMT and control samples. The four PMT samples were homogeneous according to their gene expression profiles. The genes most up-regulated (n=10) in PMT were LOC105377323/FGF1/MB/SPRY2/LOC105378029/DMP1/FGF23/BMP7/PHEX/LOC124903699. The genes most negatively regulated in PMT were LOC102724638/LOC124901874/LOC124901875/IGLL5/IGKC/IGLC1/LOC105377460/LOC105376032/IGK/IGHG1 (FDR < 0.05). We found that PMT overexpressed genes that are typical for osteoblast activity and differentiation including the most known OPG, RANKL (KEGG: p-value 0.03). We also found increased expression of the Wnt signaling antagonists SOST, DKK1 (KEGG: p-value 0.02). In PMT we found upregulated genes that are typical for secretory active osteocytes surrounded by high phosphate(FGF23/DMP1/ENPP1/PHEX/GALNT3/FAM20C/AKNA/DSPP/MEPE/EN1). Genes and pathways related to mineral ion transport were also up-regulated: Phospholipase D signaling pathway (KEGG p-value 0.003); signaling receptor binding (GO p-value < 0.001); solute: sodium symporter activity (GO p-value 0.004); calcium ion binding (GO < 0.001) and PiT1 (SLC20A1), which encodes the inorganic phosphate transporter. We found that PMT highly expressed osteopontin, CENPK and genes involved in PI3K/AKT (KEGG: p-value 0.006); ERK1/2 pathways (KEGG p-value 0.02) that are associated with castrate-resistant prostate cancer. The most up-regulated pathways in PMT were ECM-receptor interaction and gastric cancer related genes. We identified human membrane protein genes that were highly expressed in the PMT compared to control tissue PHEX/SYT12/PCDH7/RAMP1/CD44/NRG3/ILDR2/ECEL1/CHST3/ LRFN4/PCDH9, FGFR1/EVA1A/AREG/PTGIS/VSIG2/ENPP1/NRCAM/WSCD2.Conclusion: PMT expresses gene that are typical for secretory active osteoblast cells, including RANKL/OPG, phosphaturic genes, and wnt signaling antagonists. Newly identified gene expression profiles may expand our knowledge on diagnostics and therapeutic intervention in PMT.

Phosphate Signaling Is Mediated via Parathyroid Hormone Receptor 1-PLC-PKC Pathway in Committed Osteogenic Cells
*Nadine Robert[1], Sandeep Chaudhary[2], Mairobys Socorro[1], Sana Khalid[1], Catherine Roberts[1], Juan Taboas[1], Dobrawa Napierala[1]. [1]University of Pittsburgh, United States. [2]Institute of Oral Health Research, University of Alabama at Birmingham, United States

Phosphate (Pi) is a main component of hydroxyapatite crystals that form the skeletal tissues. Pi also acts as a signaling molecule to regulate mineralization. Previous studies demonstrated the involvement of Na+/Pi cotransporters, FGFR1 and Erk1/2 kinase in Pi signaling. However, the molecular mechanisms of Pi sensing and cellular mediators of Erk1/2 activation in response to Pi have not been elucidated. Our goal is to decipher Pi signaling in cells producing bone (osteoblasts) and dentin (odontoblasts). Hence, we selected two committed osteogenic cell lines, the 17IIA11 odontoblast and MLO-A5 osteoblast/pre-osteocytes, which rapidly undergo mineralization in standard osteogenic conditions. From two independent lines of experiments, we observed the 17IIA11 cells failed to respond to Pi, as evaluated by Erk1/2 activation, when the parathyroid hormone receptor 1 (Pth1r) expression is downregulated. Therefore, we hypothesized that Pth1r is required for Pi signaling in committed osteogenic cells. To test this hypothesis, we used shRNA technologies to generate Pth1r-deficient 17IIA11 and MLOA5 stable cell lines. Unlike WT and shScr controls, Pth1r-deficient cells failed to activate Erk1/2 in response to stimulation with Pi nor mineralized under osteogenic conditions. As Pth1r can modulate various signaling cascades, including protein kinase A (PKA)-cAMP and phospholipase C (PLC)-protein kinase C (PKC), we analyzed which signaling axis downstream of Pth1r transmits the response to Pi in the presence and absence of specific pharmacological inhibitors. PKA inhibition with H-89 did not prevent Erk1/2 phosphorylation (pErk1/2) whereas inhibition of phospholipase C (PLC) with D609 attenuated that response. In addition, we observed a dose-dependent decrease of pErk1/2 levels in comparison to untreated controls when PKCs were inhibited by pan-classical PKC inhibitor Bisindolylmaleimide I (GF109203X). To identify which PKC isoform is involved in Pi signaling, we utilized two selective PKC inhibitors Sotrastaurin (inhibits classical PKCs- PKC? and PKC?, but not PKC?) and Staurosporine (inhibits PKC? and PKC?, but not PKC?). We observed a dose-dependent decrease in Erk1/2 activity only with Staurosporin, while Sotrastaurin had no effect on pErk1/2. Our in vitro studies in committed osteogenic cells propose the Pth1r as a candidate receptor/sensor of Pi, that mediates Pi signaling through PLC-PKC? axis.

A High-Resolution Investigation Into the Impact of Phosphate Homeostasis Dysregulation on Carbon Metabolism in Osteoblasts
*JIE REN GERALD HAR[1], Dylan P. Kuennen[1], Maciek R. Antoniewicz[2], Lauren E. Surface[1]. [1]University of Michigan School of Dentistry, United States. [2]University of Michigan, United States

Background: Chronic kidney disease mineral and bone disorder (CKD-MBD) leads to skeletal fragility, which diminishes the quality of life of patients with CKD. Yet, the molecular mechanisms that mediate the impact of CKD-MBD on bone strength and metabolism are not well-understood. Against this backdrop, we investigate how CKD-induced hyperphosphatemia - a well-characterized indicator of disease progression - influences carbon metabolism in osteogenic cells. Using MC3T3-E1 cells as a model for osteoblasts, we analyzed the impact of hyperphosphatemia on metabolic fluxes over the course of osteoblast differentiation.Method: Hyperphosphatemic conditions were simulated by exposing differentiated and undifferentiated MC3T3-E1 cells to culture media supplemented with 10 mM sodium phosphate (Pi). A GC-MS-based method was employed for the quantification of concentration of metabolites in the culture media at multiple time points over 24 hours. Metabolic fluxes were then calculated from the change in concentration of metabolites in the culture medium normalized to time interval and cell count (Fig. A).Results: We observed that high Pi stimulates an increase in metabolite consumption or production. Subjecting MC3T3-E1 cells to high Pi led to an increase in glycolysis throughout the course of differentiation. Exemplifying this: the presence of high Pi increased lactate production rates by 48% at Day 0 of differentiation, and 75% at Day 21 of differentiation compared to the respective sodium sulfate control. High Pi also increased the flux of TCA cycle-related metabolites - at Day 21 of differentiation, cells cultured in high Pi exhibited a 76% increase in Gln consumption and 77% increase in Cit production against the negative control.We also compared changes in metabolic fluxes over the course of differentiation. Comparing cells at Day 21 against Day 0 of differentiation, we observed that the Gln uptake per cell decreased by 90% while Glu and Asp uptake per cell increased significantly by 235% and 96% respectively over the course of differentiation. In ongoing work, we are employing 13C-metabolic flux analysis to decipher how Pi affects intracellular metabolic fluxes during osteoblast differentiation.In summary, we have established an in vitro workflow to study the local impact of hyperphosphatemia on osteogenic cells. Our findings presented here provide motivation to investigate the consequences of CKD and hyperphosphatemia on bone metabolism in vivo.

A pilot studies the Relationship between Nucleolin and Copine7-mediated Autophagy
*Joo-Cheol Park[1], Min-Soo Kang[1]. [1]Seoul national university, Republic of Korea

Purpose : we aimed to investigate the relationship between nucleolin and copine7-mediated autophagy in different cell types.Method : To confirm the expression of nucleolin in several cells, we confirmed the expression of nucleolins in normal cells that were treated with noting. And we verified that autophagy was also caused by copine7 in other cells expecting hDPC. Subsequently, nucleolin siRNA and selcopintide were treated and changes were observed in cells with and without autophagy.Results : Expression of nucleolin was confirmed in human dental pulp cells(hDPCs), human periodontal ligament cells(hPDLs),

human gingival fibroblasts(hGF), and SH-SY5Y cells, a neuroblastoma cell line. As a result, nucleolin was expressed in the nucleus of all cells.Conclusions : Nucleolin has been expressed in all cells, especially in the nucleus.

Genome-wide Analyses Reveal TGF? Signaling as a Regulator of Osteogenic Phosphate Sensing *Dylan Kuennen[1], Long Tran[2], Michael Mannstadt[3], Lauren Surface[2]. [1]University of Michigan, United States. [2]University of Michigan School of Dentistry, United States. [3]Massachusetts General Hospital Harvard Medical School, United States

Organismal phosphate (Pi) is an essential regulator of many cellular processes necessary for healthy tissue and organismal function. The skeleton is a key regulatory site in the control of organismal Pi homeostasis. However, the mechanisms of the Pi-sensing circuitry in osteogenic cells are poorly understood. Using in vitro approaches, our goal is to elucidate how the factors responsible for serum Pi sensing in osteogenic cells enable the endocrine Pi response to inform future therapeutics.To understand the transcriptional response in osteogenic cells during exposure to Pi, we performed an RNA-seq time course on MC3T3-E1, a pre-osteoblast cell line, and OCY454, an osteocytic cell line. We observed differential expression of gene categories related to bone mineralization as well as TGF?, MAPK, and EGF signaling. Based on these findings, we developed two flow cytometry-based readouts of the response to increased extracellular Pi; a Dmp1-2A-mCherry fluorescent reporter and a cell surface antigen stained with an antibody (SEMA7A). Using flow cytometry, we confirmed that inhibiting FGFR1 and ERK signaling blocks these responses to Pi. To identify factors that mediate Pi sensing, we combined our reporters with genome-wide CRISPRi screens and identified ~38 hits common to screens in both reporters. To prioritize physiologically relevant pathways, we intersected these hits with loci associated with circulating Pi and FGF23 levels by GWAS, and identified TGFB2 as a hit that is also top genetic polymorphism associated circulating FGF23 levels, supporting a potential physiological role for TGF? signaling in controlling the endocrine Pi response.We find that TGF-?2 co-treated with Pi enhances the response of osteogenic cells both increasing early Erk phosphorylation and the response of our reporters after 24 hours. We observe that TGF? signaling affects calcium (Ca2+) flux, leading to an increase in extracellular Ca2+, and that an inhibitor of store-operated calcium entry (SOCE) blocks the effect of TGF-?2 suggesting that SOCE mediates this response. Ca2+ may boost the response of osteogenic cells to Pi, likely through calciprotein particle (CPP) formation. We hypothesize that TGF-?2 increases the available extracellular Ca2+ to form CPP with Pi, thereby boosting the Pi response. These results may provide critical insights into Pi homeostasis, particularly in the setting of chronic kidney disease in which both circulating TGF? and FGF23 levels are increased.

Crispant screening in zebrafish as a promising approach for rapid functional screening of osteoporosis candidate genes and known genes for Osteogenesis Imperfecta. *Sophie Debaenst[1], Hanna De Saffel[1], Jan Willem Bek[1], Adelbert De Clercq[1], Tamara Jarayseh[1], Lauren Sahd[1], Andy Willaert[1], Paul Coucke[1]. [1]Ghent University , Belgium

Genome-wide association studies have improved our understanding of the genetic architecture of common complex diseases such as osteoporosis. Nevertheless, to attribute functional skeletal contributions of candidate genes to osteoporosis-related traits and to identify underlying pathogenic mechanisms in other skeletal diseases, such as Osteogenesis Imperfecta, there is a need for efficient and cost-effective in vivo functional testing. To get a quick insight into these pathogenic mechanisms, we aimed to develop a rapid and cost-effective approach for in vivo functional validation of candidate genes through CRISPR-based reverse genetic screens in the zebrafish model system. We used the so-called crispant screening approach, based on CRISPR/Cas9 technology, in order to phenotype directly in FO mosaic founder zebrafish. Compared to a stable knockout model, crispants reduce model generation time, enabling the validation of a large set of genes in a short period of time. Recently, we delivered proof-of-concept for this screening tool by reporting phenotypic and molecular similarities between a stable KO mutant and a crispant for LRP5. In this study, we selected a panel of 6 OI genes (creb3l1, ifitm5, mbtps2, sec24d, serpinf1 and sparc) and 4 Osteoporosis genes (aldh7a1, daam2, esr1 and sost) and micro-injected CRISPR/Cas9 components (gRNA/Cas9) targeting the gene of interest, in one-cell stage zebrafish embryos with an osteoblast-specific Tg(osx:Kaede) transgenic background. NGS amplicon sequencing of pools of injected embryos revealed out-of-frame efficiencies higher than 70%, indicating a high fraction of knock-out alleles for the 10 genes and thus resembling a stable knock-out model. Phenotypic analysis was performed at 7, 14 and 90 days after fertilization, though fluorescence microscopy (osteoblasts), alizarin red bone staining and micro-CT analysis for quantitative analysis of the skeleton. Molecular analysis was performed at 7 dpf through qPCR. Preliminar results are promising, showing skeletal abnormalities, such as fusions, callus formation in the vertebral arches and ectopic mineralization at 90 dpf. Taken together, we showed that crispant screening in zebrafish is a promising approach for rapid functional screening. Moreover, the crispants have the potential to provide new insights into the role of these genes in skeletal biology and can be used as a tool for osteogenic compound screening.

Aging-related declines in skeletal muscle grip strength are prevented via daily oral treatment with an Aryl hydrocarbon receptor (AhR) antagonist, BAY2416964 *KANGLUN YU[3], Meghan McGee-Lawrence[2], DIMA ALHAMAD[3], HUSAM BENSRETI[3], Anik Tuladhar[5], Caihong Dai[5], Joseph Shaver[5], Kehong Ding[5], Rafal Pacholczyk[5], Sadanand Fulzele[5], Carlos Isales[5], Mark Hamrick[5], William Hill[6, 3], . [2]Medical College of Georgia, Augusta University, United States. [3], United States. [5]Augusta University, . [5]Augusta University, United States. [6]Medical University of South Carolina, United States

The Aryl hydrocarbon receptor (AhR) is a cytosolic transcription factor whose activation can be beneficial or harmful; while AhR signaling is important for the detoxification of certain ligands, prolonged or chronic AhR activation may have negative effects on musculoskeletal function. As endogenous AhR ligands like kynurenine increase with age, we tested whether inhibition of AhR would confer a protective effect on the musculoskeletal system during aging.Female C57BL/6 mice were obtained from the NIA rodent colony and treated with vehicle (VEH; Ethanol 10/Solutol 40/Water 50) or BAY2416964 (BAY; 30 mg/kg, Targetmol T10270) via daily oral gavage 5 d/wk for 8 wks (n=8-10 per group). Skeletal muscle endurance and strength were assessed at 0, 4, and 8 wks of treatment via hang-time tests and grip strength meter (Bioseb BIO-GS3). DXA was performed at the same time points to assess body composition and bone density. Skeletal muscles (TA, EDL, Soleus, Quads) and long bones were collected at sacrifice. Muscle fiber size was measured from H&E-stained TA sections. The left tibia and femur from each mouse were used for static and dynamic histomorphometry and microCT analyses. Serum P1NP (bone formation; IDS #AC-33F13) and TRAcP5b (bone resorption; IDS #SB-TR103) were quantified via ELISA, and inflammatory cytokines were measured using a Legendplex panel (Mouse Inflammation 13-Plex). Body weights were stable over the 8-week study in both groups. VEH-treated animals demonstrated a significant age-related decline in forelimb grip strength during the study, but this decline was prevented by BAY (p-treatment <0.0001) by the 8th week, BAY-treated mice had significantly (p=0.0002) greater grip strength than VEH-treated mice. Muscle endurance (hang time), mass, and fiber sizes were unaffected; measurements of mitochondrial function and NMJ morphology are ongoing. Bone endpoints were generally unaffected in the current study, with microCT measures of bone mass and serum and histology-based metrics of bone remodeling largely comparable between VEH- and BAY-treated mice. The minimal impact on bone may have been, in part, due to low bone mass in the aged female mice at the onset of treatment. Together these data suggest that inhibiting AhR via BAY2416964 may prevent age-related declines in skeletal muscle function; future studies will incorporate earlier onset of treatment to determine if benefits observed in muscle function can be conveyed to the bone.

Active mTOR is required for de novo bone formation in the regenerating mouse digit tip *Dominik Hanetseder[1], Barbara Schaedl[1], Larry Suva[2], Dana Gaddy[3], Ken Muneoka[4], Lindsay Dawson[5], Regina Brunauer[1]. [1]LBG Ludwig Boltzmann Institute for Traumatology, Austria. [2]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States. [3]College of Veterinary Medicine, Texas A&M University, United States. [4]Texas A&M University, . [5]Texas A&M University College of Veterinary Medicine, United States

Maintaining reparative regeneration and resilience after trauma with age is vital to extending the healthy years of life (healthspan); yet, feasible models to routinely assess resilience are lacking. Mouse digit tip regeneration is one of the few mammalian examples of epimorphic regeneration, the structural regeneration of multiple tissues that is most prominently known for salamander limb regeneration. Mouse digit tip regeneration is induced by a simple amputation surgery, proceeds through a catabolic phase, which is dominated by osteoclast-driven bone resorption, and an anabolic phase, which is dominated by osteoblast-driven bone formation. These regeneration phases are associated with distinct cellular events, are separated and possibly controlled by epidermal wound closure, can be traced in vivo, and exhibit a clearly delayed phenotype with aging. Thus, mouse digit tip regeneration can serve as a feasible model to investigate the role of geroprotector targets in bone regeneration. A central regulator of healthspan is the mTOR (mechanistic Target of Rapamycin) kinase pathway. Rapamycin, the namesake and inhibitor of mTOR, extends healthspan under homeostatic conditions, but whether there is a benefit to regeneration after injury is unknown. In this study, we treated aged (12 month old) CD1 / ICR females with a lifespan-extending regimen of rapamycin (8 mg/kg i.p. every second day) or vehicle, amputated the distal digit tips and tracked the regeneration response for up to 28 days, when regeneration is completed in young mice. We found that rapamycin does not affect the rate of bone degradation, but extends the duration of the catabolic phase, and almost completely inhibits bone formation during the anabolic phase. This inhibition of osteoblast activity is either indirect through an inhibition of epidermal wound closure, or direct through inhibition

of osteoprogenitor proliferation or differentiation. To conclude, our data suggest that geroprotectors that extend healthspan under homeostatic conditions do not necessarily improve reparative regeneration, but that they can in fact even be detrimental to healing after injury.

Mitochondrial Genetics as a Determinant of Bone Phenotype and Aging

*Sarah Catheline[1], Aric Huber[1], Sarah Murphy[1], Roman Eliseev[1]. [1]University of Rochester, United States

Osteoporosis is the most common bone disease in the world with estimated 200 million cases globally. While aging and sex steroid levels have been considered primary risk factors for osteoporosis, mitochondrial genetics and function are also increasingly recognized as determinants of bone health and aging. Recent studies show that mitochondrial genome variants (haplogroups) in different human populations have developed out of a need to modify mitochondrial coupling efficiency to generate heat based on geographical location. In humans, bone phenotype correlates to mitochondrial haplogroup type, i.e. more efficient and less thermogenic mitochondria correlate with stronger bones. Thus, we hypothesize that mitochondrial DNA (mtDNA) haplogroup and oxidative phosphorylation efficiency are determinants of bone phenotype and aging. To test this, we used two strains of mice, C57BL/6 and C3H, known to have different mtDNA haplogroups and bone phenotype. C57BL/6 mice have less efficient mitochondria than C3H mice. We also used mitochondrial-nuclear exchange (MNX) mice that feature mtDNA from either C57BL/6 or C3H mice inserted into an enucleated embryo from the opposing strain to produce C3H MNX mice or C57 MNX mice. Interestingly, micro CT reveals that despite having more efficient C3H mitochondria, C57 MNX mice show no obvious improvement over WT C57BL/6 mice in measured bone parameters at 3 or 13 months of age. In contrast, female C3H MNX mice that have less efficient C57 mitochondria show a reduction in both trabecular BV/TV and cortical thickness relative to controls at 13 months. This bone loss in the 13-month-old C3H MNX female femurs corresponded to a reduction in energy to yield during biomechanical testing. In vitro, bone marrow stromal, a.k.a. mesenchymal stem, cells (BMSCs) isolated from C57 MNX mice showed greater osteogenic potential at day 0 of culture as illustrated by enhanced alkaline phosphatase staining and increased Sparc and Ibsp expression. These results indicate that initially, C57 MNX BMSCs are more biased towards adopting an osteogenic fate than WT C57BL/6 BMSCs due to their more efficient mitochondria; however, this is no longer the case at days 7 or 14 of osteoinduction. In summary, our data suggest that there is likely sexual dimorphism in the effect of mtDNA haplotype on bone phenotype, and inserting mitochondria from C57BL/6 mice into C3H mice was successful in reducing bone volume in female mice.

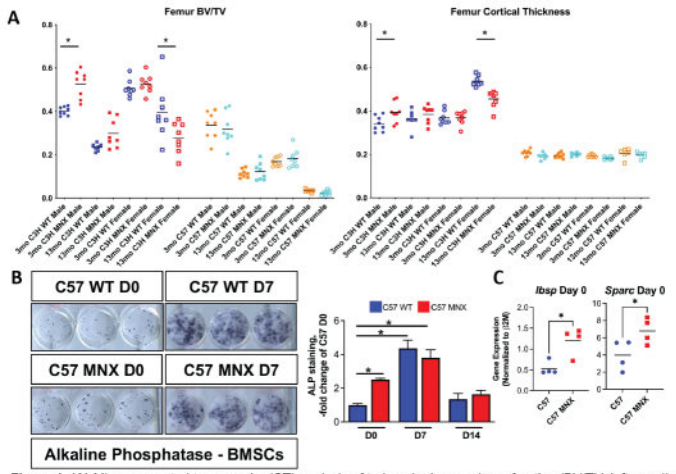

Figure 1. (A) Micro computed tomography (CT) analysis of trabecular bone volume fraction (BV/TV, left panel) and cortical thickness (right panel) from the femurs of C3H WT and C3H MNX (blue and red dots, respectively) and C57 WT and C57 MNX (orange and cyan dots) male and female mice at age 3 and 13 months (N = 8, unpaired t-tests, * indicates $p < 0.05$). **(B)** Images of bone marrow stromal cell (BMSC) isolated from C57 WT and C57 MNX and stained with alkaline phosphatase at day 0 or 7 of culture that is quantified in the graph at the right (N = 6, One way ANOVA, * indicates $p < 0.05$). (C) Quantitative RT-PCR from day 0 BMSC cultures for *Ibsp* and *Sparc* (N = 4, unpaired t-test, * indicates $p < 0.05$).

Dissecting the Diversity of Senescence in the Aged Murine Skeleton Reveals Necessity of BCL-2 Expression to Define Age-Related Senescent Cells

*Madison Doolittle[2], Dominik Saul[2], Jennifer Rowsey[2], Stephanie Vos[2], Kevin Pavelko[2], Joshua Farr[2], David Monroe[3], Sundeep Khosla[4]. [2]Mayo Clinic, United States. [2]Mayo Clinic, . [3]Mayo Foundation, United States. [4]Mayo Clinic College of Medicine, United States

Cellular senescence, a hallmark of aging, contributes to age-related bone loss, yet the cells that become senescent in vivo remain poorly understood. This is due to heterogeneity of both skeletal cell types and senescent cell signatures that present technical challenges in delineating the cell types driving this aging phenotype. To address this, we developed and validated a mass cytometry (CyTOF) panel to define, characterize, and profile skeletal senescence at the single-cell level in mice. We enzymatically digested femurs and tibias from cohorts (n=12-15) of young (6-month) and old (24-month) mice to generate single-cell suspensions, which were then purified for mesenchymal cells (Lin-CD45-) before CyTOF analysis. We found that cells positive for the senescence marker p16 were diverse in their expression of senescence-associated markers, while also containing non-senescent (Ki67+) subpopulations. Within p16+ cells, we found a subset positive for the apoptosis resistance marker BCL-2 that was non-proliferative (Ki67-) (Panel A, B; black arrows) and expressed inflammatory and DNA damage markers at a high level. In addition to CyTOF, we also identified these p16+Ki67-BCL2+ ("p16KB") cells using scRNA-seq (Panel C), which revealed that this was a highly secretory cell population that was enriched in senescence-associated secretory phenotype (SASP) gene expression, applied with the SenMayo geneset (Panel D). Altogether, these p16KB cells fulfilled major criteria for senescence through a multiparametric approach. In our skeletal cell clusters, we found that both p16+ and p16KB cells were upregulated in an osteolineage population defined by high expression of CD24. We found this population to be the predominant cluster that was cleared through p16+ senescent cell clearance in aged INK-ATTAC mice. Additionally, we found that CD24 osteolineage cells were also cleared in the bones of aged wild-type (C57BL/6N) mice treated with the senolytic combination of Dasatinib and Quercetin. Upon isolation, CD24+ mesenchymal cells from the bones of aged mice exhibit drastically reduced colony formation efficiency and spontaneous senescence-associated ?-galactosidase expression, consistent with functional outcomes of senescence. In summary, we identified senescent cells in the bone microenvironment through a multiparametric approach and revealed CD24 as a marker present on senescent osteolineage cells in the murine skeleton that are targeted by senolytic therapy.

Cellular Senescence is a Modifiable Mediator of Skeletal Fragility in Mice with Type 2 Diabetes

*Mitchell Froemming[2], Vojt?ch Pa?ízek[2], MADISON DOOLITTLE[2], Dominik Saul[2], Jennifer Rowsey[2], Stephanie Vos[2], David Monroe[3], Sundeep Khosla[4], Joshua Farr[2]. [2]Mayo Clinic, United States. [2]Mayo Clinic, . [3]Mayo Foundation, United States. [4]Mayo Clinic College of Medicine, United States

Type 2 diabetes (T2D) is a major risk factor for multiple health complications in humans, including poor bone quality and fractures. However, the mechanisms that cause diabetic complications remain unclear. Senescence is a stress-induced growth arrest cell fate that contributes to several pathologies. Characterized by upregulated p16Ink4a expression, apoptosis resistance, telomeric DNA damage (telomere-associated foci [TAF]), and a distinct senescence-associated secretory phenotype (SASP), senescent cells are known to accumulate in various tissues with aging, including bone, where they disrupt tissue function. Despite evidence demonstrating that senescent cells accumulate prematurely in multiple tissues with T2D and promote metabolic dysfunction, the extent to which bone-resident cells in T2D are prone to senescence is incompletely understood. We previously found skeletal fragility, altered bone turnover, and accelerated osteocyte senescence in mice with T2D. Here, we report in T2D mice (relative to age- and sex-matched controls) that osteo- and adipo-progenitors (Lin-/LepR+) from T2D mice expressed significantly higher p16Ink4a mRNA (Panel A) together with several SASP factors. Further, through analysis of various hematopoietic cell populations, we found that p16Ink4a mRNA was significantly higher in B-cells, T-cells and myeloid (Cd14+) cells from T2D mice (Panel A). Using the combination of rt-qPCR, mass cytometry (CyTOF), and complementary imaging techniques, we found that T2D-derived Cd14+ myeloid cells displayed a dramatic SASP (Panel B) and had higher protein levels of p16 and Bcl2 (an anti-apoptotic protein upregulated with senescence) (Panel C). Although these Cd14+ myeloid cells from T2D mice had low and non-significantly different levels of

Sunday Orals

proliferation (assessed by Ki67), interestingly they displayed significantly higher levels of both pATM (a DNA damage marker) and TAFs (Panels C-D). We next removed senescent cells from adult (6-month-old) female and male T2D mice using both genetic (p16-ATTAC) and pharmacological (senolytic) approaches, which after 4 months did not affect trabecular bone, but significantly increased cortical thickness, reduced cortical porosity, and improved femoral strength. These improvements were associated with decreased osteoclasts, increased osteoblasts, and reduced marrow fat. Collectively, our data provide compelling evidence for cellular senescence as a hallmark and modifiable mediator of skeletal fragility in T2D.

Senescent Cells Evade Macrophage Immune Clearance in Connective Tissue *Zoltan Szilagyi[1], Samantha Przybelski[2], Takako Chikenji[3], Yuki Saito[4], Peter Amadio[2], Tamara Tchkonia[2], James Kirkland[2], Anne Gingery[2]. [1]Indiana University School of Medicine, United States. [2]Mayo Clinic, United States. [3]Hokkaido University, Japan. [4]Sapporo Medical University, Japan

Senescent cell accumulation in musculoskeletal tissues has been increasingly associated with tissue aging and pathology. Connective tissue is important for musculoskeletal structure, protection, and delivery of nutrients to neighboring tissues. Aging connective tissue becomes fibrotic and drives pathologies, limiting activity and range of motion all of which are essential for patient musculoskeletal health and improved health span. We have previously shown that senescent cells accumulate in multiple musculoskeletal connective tissues. Our overarching hypothesis is that senescent cell accumulation contributes to age-related dysfunction of connective tissue by upregulation of immune checkpoint regulators which prevent the clearance of senescent cells. Here we characterized the senescent cell populations in multiple connective tissues from patients and aged animal models. We found that senescent cells from these tissues expressed multiple markers of cellular senescence including p16, p15, p53, and SABG. We also found that immune evasion markers such as CD47, PDL1, and PDL2 were upregulated. Further senescent cells upregulated fibrosis-related genes such as THBS1, which encode thrombospondin 1 protein (TSP1), a CD47 signaling receptor. Using the p16 INK-ATTAC mouse model we found that PD-L1, PD-L2, and CD47 significantly downregulated upon activation of the INK-ATTAC "suicide" transgene which specifically targets senescent cells for removal. We also found that senescence associated secretory factors including TGFß, PAI-1 and interferons type I and type II are expressed in senescent connective tissues and that these factors drive expression of immune evasion markers on senescent cells. When we ablated p16 positive senescent cells using aged mice expressing the INK-ATTAC "suicide" transgene we found that PD-L1, PD-L2, and CD47 were significantly down regulated. Further using a THP-1 macrophage model we assessed the ability of senescent cells to evade macrophage phagocytosis and found that neutralizing antibody to CD47 attenuated immune evasion. In these model systems we found that senescent cells escaped from macrophage phagocytosis and promoted the proliferation of neighboring cells driving tissue dysfunction and pathology. This work indicates that targeting immune evasion as well as the anti-apoptotic pathways in senescent cells may provide a novel therapeutic strategy for removal of senescent cells from aged or diseased musculoskeletal tissues.

Osterix-Cre Conditional Indoleamine 2, 3 dioxygenase Knockout Mice were not Protected against Orchiectomy-induced Bone Loss Suggesting that Osteoclasts may be the Main Mediator of IDO1 Effects in Bone *Baolin Kang[1], Wendy Bollag[2], Ke-Hong Ding[1], Debra Irsik[3], Jianrui Xu[1], Meghan McGee-Lawrence[4], Xingming Shi[1], William Hill[5], Sadanand Fulzele[1], Mark Hamrick[1], Carlos Isales[1]. [1]Augusta University, United States. [2]Augusta University and Charles Norwood VAH, United States. [3]Charlie Norwood Augusta VAH, United States. [4]Medical College of Georgia, Augusta University, United States. [5]Medical University of South Carolina, United States

Tryptophan (Trp) is an essential amino acid, and the initial step in its metabolism occurs through the enzymes indoleamine and tryptophan 2,3-dioxygenase (IDO and TDO). We have previously shown that some tryptophan metabolites such as kynurenine (kyn), accumulate with age and contribute to age-induced bone loss, although other downstream tryptophan metabolites have been postulated to have bone-promoting effects. We hypothesized that knocking out IDO1 would be protective against high bone turnover states such as hypogonadism. We had previously reported that a global IDO1 knockout (KO) was protective against trabecular bone loss in orchiectomized (Orx) C57BL/6 mice. To further explore IDO1's role in bone turnover, we used a conditional IDO1 KO mouse (generated by EUCOMM/IMPC) using an osterix-promoter-driven Cre possessing a tet off element, because of concerns of effects of knocking out osterix at an early age on bone development. In an IACUC-approved protocol using male conditional IDO1 KO (cKO) C57BL/6 mice and a sample size of 5 mice/group, we Orx 8-month-old mice and placed them either on a regular or doxycycline-containing diet for eight weeks. At the end of that time mice were sacrificed and bone parameters measured by Digimus and uCT and serum PYD and Trp metabolites determined using ELISA and LC/MS, calibrated using known concentrations of the various metabolites as standards, respectively. There was no significant difference between bone parameters measured: (1)BMD-0.0688+0.0046 vs 0.0647+0.006 (Con vs cKO, gm/cm2; (2)BV/TV-34.6+2.8 vs 33.5+2.7; (3)TbTh-0.166+0.010 vs 0.164+0.013; (4) TbSp-0.470+0.0029 vs 0.471+0.0016; (5)Tb#-2.076+0.088 vs 2.037+0.075. Our results for Trp and its metabolites were only significantly different for xanthurenic acid levels: (1)Trp-7213+/-1318 vs 5954+1270 (nmol/L means+SD, Controls vs cKO for all); (2) kyn-121+/-26 vs 121+/-20; (3) picolinic acid-1656+/-274 vs 1803+/-250m; (4)xanthurenic acid: 19+/-2 vs 14+/-2 (Control vs cKO p<0.02); and (5)quinolinic acid-279+/-25 vs 281+/-93. We also measured PYD levels as an index of bone breakdown and there was no significant difference between the two groups: 3.2+1.4 vs 2.8+1.0 (nmol/L means+SD Control vs cKO, p=0.057). These data suggest that bone osteoprogenitor cell-specific knockout of IDO has little effect on bone; therefore, in the global IDO knockout bone protective effects are likely driven by a bone resorptive role for IDO in osteoclasts during a high bone turnover state such as Orx.

Detrimental Effects of ?2-Microglobulin on Muscle Metabolism: Evidence from In Vitro, Animal, and Human Research *Beom-Jun Kim[1], So Jeong Park[2], Jin Young Lee[2], Kee ho Song[3]. [1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Republic of Korea. [2]Asan Institute for Life Sciences, Asan Medical Center, University of Ulsan College of Medicine, Republic of Korea. [3]Division of Endocrinology and Metabolism, Konkuk University Medical Center, Konkuk University School of Medicine, Republic of Korea

Background: The ?2-Microglobulin (B2M) has been receiving attention as a potential pro-aging factor. Accordingly, it may be involved in muscle metabolism and sarcopenia, a key component of aging phenotypes. To clarify this possibility, we investigated the effects of B2M on in vitro and animal muscle biology and its clinical relevance for sarcopenia parameters in older adults. Methods: In vitro myogenesis was induced in mouse C2C12 myoblasts with 2% horse serum. For in vivo research, C57BL/6 mice aged 3 months were intraperitoneally given 250 ?g of B2M daily, and muscular alterations were assessed one month later. Human blood samples were collected from 158 participants who underwent evaluation of muscle mass and function in an outpatient geriatric clinic of a teaching hospital. Sarcopenia and related parameters were determined using cutoff values for the Asian population. Serum B2M levels were measured using an enzyme-linked immunosorbent assay. Results: Recombinant B2M treatment suppressed myogenesis from mouse C2C12 myoblasts in a dose-dependent manner, and consistently reduced the expression of myogenic differentiation markers. In addition, B2M significantly increased intracellular reactive oxygen species (ROS) levels in myotubes, and treatment with N-acetyl cysteine, a potent biological thiol antioxidant, reversed the decrease of myotube area, myotube area per myotube, nucleus number per myotube, and fusion index by B2M through decreasing oxidative stress. Animal experiments showed that mice with systemic B2M treatment exhibited significantly smaller cross-sectional area of tibialis anterior and soleus muscle, weaker grip strength, shorter grid hanging time, and decreased latency time to fall off the rotating rod, compared to untreated controls. In a clinical study, serum B2M levels were inversely associated with grip strength, usual gait speed and short physical performance battery (SPPB) total score after adjustment for age, sex, and body mass index, whereas sarcopenia phenotype score showed a positive association. Consistently, higher serum B2M levels were associated with higher risk for weak grip strength, slow gait speed, low SPPB total score, and poor physical performance.

Conclusion: These results provide experimental evidence that B2M exerted detrimental effects on muscle metabolism mainly by increasing oxidative stress. Furthermore, we made an effort to translate the results of in vitro and animal research into clinical implication and found that circulating B2M could be one of blood-based biomarkers to predict poor muscle health in older adults.

APOA1 and APOE proteins related to LXR/RXR pathways as a potential proxy for progression of sarcopenia in community-based prospective cohort

*Sung Hye Kong[2], Seung Shin Park[2], Jung Hee Kim[2], SANG WAN KIM[3], Chan Soo Shin[4], Ok Hee Jeon[5], Do Hyun Han[2]. [2]Seoul National University Hospital, Republic of Korea. [2]Seoul National University Hospital, . [3]Seoul National University College of Medicine, Boramae Medical Center, Republic of Korea. [4]Seoul National University College of Medicine, Republic of Korea. [5]Korea University Colloege of Medicine, Republic of Korea

The study aimed to find protein markers as a proxy for the sarcopenia progression, and markers associated with muscle mass and strength..In this prospective community-based cohort study of the geriatric population aged 70-84 years, muscle mass, function, and performance were measured at the baseline and after 2 years. Among them, 63 participants were nonsarcopenic and the baseline but developed severe sarcopenia after 2 years (non-to-sarcopenic group). As the age, sex, and body mass index (BMI)-matched control, 65 participants who stayed nonsarcopenic both at the baseline and follow-up (stayed robust group) and 43 participants who were severe sarcopenic both at the baseline and follow-up (stayed sarcopenic group) were included. We performed liquid chromatography with tandem mass spectrometry using plasma samples. The definition of sarcopenia was based on the Consensus of Asian Working Groups for Sarcopenia in 2019.In baseline characteristics, the mean age of the patients was 78.5 years and 45% were female. Age, BMI, and underlying diseases were similar among groups, while participants in stayed sarcopenic group were more likely to be men than the other groups. In proteomic analysis, ALDOB, LECT2, USP15, KLKB1, KNG1, APOA1, APOA2, TF, OGN, C4BPB, and AXL proteins were differentially expressed between participants in stayed robust and non-to-sarcopenic groups. CSF1R, KLKB1, PRAP1, ICOSLG, CFD, QSOX1, PODXL, CST3, APOA1, APOE, RBP4, AMBP, SLPI, GAPDH, S100A8, S100A9, C7, IGFBP6, PTGDS, LYZ, B2M, EFEMP1, and MMRN2 proteins were differentially expressed between participants in stayed robust and stayed sarcopenic groups. Interestingly, in pathway analysis of differentially expressed proteins, the LXR-RXR pathway, which represents cholesterol efflux, was one of the most significantly associated pathways between participants in stayed robust and non-to-sarcopenic groups. In association analysis with muscle mass and strength, LXR-RXR pathway was also correlated with both muscle mass and strength, and protein-protein interaction analysis showed key proteins of APOE and APOA1 for muscle mass and strength, respectively. Along with the proteomic analysis, baseline serum HDL levels were significantly different among groups, highest in the stayed robust group, and lowest in the stayed sarcopenic group. Baseline HDL levels were negatively associated with baseline and follow-up appendicular muscle mass in the association analysis.In conclusion, the proteomic analysis showed that 11 and 23 proteins were differentially expressed in participants in non-to-sarcopenic, and stayed sarcopenic groups compared to stayed robust group, respectively. The pathway analysis revealed that LXR-RXR pathway was the key pathway to discriminate stayed sarcopenic and non-to-sarcopenic groups and suggested APOE and APOA1 as key protein markers for muscle mass and strength.

Soft tissue massage alters RANTES and IL-4 cytokine levels in a rat model of induced low back pain

*Carmela Marciano[1], Taylor Hiland[1], Krista Jackson[1], SIERRA STREET[2], Carson Maris[1], Andrew Ehrsam[1], Julia Hum[1], M. Terry Loghmani[3], Tien-Min G Chu[3], Jonathan Lowery[1]. [1]Marian University, United States. [2], . [3]Indiana University, United States

Low back pain (LBP) is a common musculoskeletal complaint that impedes physical function and mobility. Management often involves pain medication such as opioids but there is a need for non-pharmacological and non-invasive interventions. Prior work in human subjects indicates that soft tissue manipulation (STM) such as massage can accelerate return-to-function, improve mental and emotional wellbeing, and reduce the need for opioid medication usage. However, heterogeneity of lifestyles and body conditions, potential co-morbidities, and the inherent mind-body aspect of manual therapies complicate our understanding of the molecular mechanisms underlying these findings. Such a knowledge gap may prevent future therapeutic potential and widespread adoption of this non-invasive approach to pain management and rehabilitation. Thus, in a prior study, we employed a rat model of chronic LBP using Complete Freund's Adjuvant and established a system for delivering instrument-assisted STM (IASTM) wherein force, direction, and duration of therapy were reproducibly applied across conscious subjects. This advancement allowed for demonstrating that IASTM improved gait in rats with chronic LBP and altered plasma levels of several biomarkers such as RANTES. In the present study, we advance this work to evaluate potential changes in soft tissue levels of more than thirty pro- or anti-inflammatory cytokines following IASTM in rats with chronic LBP. Our results indicate that, compared to sham touch, IASTM is associated with reduced soft tissue levels of RANTES and increased soft tissue levels of IL-4, which are pro-inflammatory and anti-inflammatory cytokines, respectively by 120 minutes post-treatment. IASTM was not associated with tissue-level changes in CXCL7, ICAM-1, IL1-ra, IL-6, IP-10/CXCL10, L-selectin, LIX, TNF-?, or VEGF at either thirty or 120 minutes post-treatment. Combined, our findings suggest that IASTM exerts tissue-level effects that are associated with improved clinical outcomes and potentially beneficial changes in pro/anti-inflammatory cytokines in circulation and at the tissue level.

Single cell RNAseq analysis reveals that osteoblast biosynthetic activity as well as number decrease with aging

*Intawat Nookaew[1], Aaron Warren[1], Ha-Neui Kim[2], Jinhu Xiong[3], Charles O'Brien[3], Maria Jose Almeida[4]. [1]University of Arkansas for Medical Sciences, United States. [2]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States. [3]Univ of Arkansas for Medical Sciences, United States. [4]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, United States

Bone formation decreases with age both at the periosteum and in endocortical bone but the mechanisms are unclear. Several aging mechanisms have been implicated in the loss of bone mass with aging, including mitochondria dysfunction, loss of proteostasis, and senescence. To examine how transcriptional programs change in a cell-type specific manner with aging, we performed single cell RNA-sequencing (scRNAseq) of mesenchymal cells present at the endosteum and periosteum of mouse bone. To do this, endosteal or periosteal cells were isolated from long bones of 6 and 22 month old female mice expressing tdTomato in cells targeted by an Osx1-Cre transgene. Cells expressing tdTomato were isolated by FACS and subjected to scRNAseq using the 10X Chromium platform. An initial UMAP plot and cluster analysis, after harmonization of cells from mice of the two ages, revealed 9 clusters based on expression of cluster-specific markers, including osteocytes, osteoblasts, pre-osteoblasts, osteo-CAR, osteo-X, adipo-CAR, chondrocytes, fibro-1, and fibro2. In young mice, osteoblasts constituted the majority of the cells at the endosteum while osteo-X cells, characterized by high expression of periostin, were the major cell type at the periosteum. Aging led to a decrease in the osteoblast proportion from 60 to 27% at the endosteum and from 6.8 to 2.4% at the periosteum. Gene Ontology enrichment analysis of differentially expressed genes in osteoblasts of the endosteum revealed that processes related to senescence, inflammation, apoptosis, and translation were increased, while processes related to mitochondria and endoplasmatic reticulum were decreased. In contrast, no changes in these processes were detected in cells from the periosteum. On the other hand, processes related to collagen fibril organization and extracellular matrix, as well as mRNAs encoding collagens and other extracellular matrix proteins, such as Dcn, Lum, and Bglap, decreased with age in osteoblasts, pre-osteoblasts and osteo-CAR cells at both sites. In addition, ribosome and ribonucleoprotein related processes were increased with age in both osteoblast at both sites. Overall, these results suggest that a decrease in osteoblast vigor contributes to the decrease in bone formation that occurs with age at both the periosteum and the endosteum. Moreover, an additional mechanism contributing to reduced bone formation at the endosteum may be increased senescence of osteoblasts and their progenitors.

Deletion of the Mitochondrial Kinase PINK1 Does Not Affect Age-Related Bone Loss *Kimberly Richardson[1], Aaron Warren[1], Maria Jose Almeida[2], Ha-Neui Kim[3]. [1]University of Arkansas for Medical Sciences, United States. [2]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, United States. [3]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States

PINK1 kinase and NAD+-dependent deacetylase SIRT3, localized in mitochondria, play a role in pathological conditions, such as aging, cancer, and Parkinson's disease, most likely by regulating mitophagy. Notably, SIRT3/PINK1-mediated mitophagy does not play a major role under non-stressed conditions. Under stress conditions, however, Sirt3 or Pink1 knockout (KO) mice exhibit overt differences compared to littermate controls. This is in line with evidence that deletion of Sirt3 has no effect on the skeletons of young mice, but Sirt3 KO mice are protected from age-associated bone loss. Nonetheless, the functional significance of SIRT3 deacetylation of PINK1 in the control of mitophagy has not been demonstrated in bone cells. We have investigated here whether PINK1 stimulates osteoclast mitophagy, maintains a functional mitochondrial network, or whether it contributes to age-related bone loss. First, we generated rabbit polyclonal antibodies specific for lysine acetylated PINK1 (K24 and K33). Osteoclasts lacking Sirt3 from aged Sirt3 null or conditional KO mice (under the control of the LysM promoter) exhibited hyperacetylation of PINK1. These results suggest that SIRT3-induced deacetylation of PINK1 might act as a molecular switch to activate mitophagy in osteoclasts during skeletal aging. To address this hypothesis, mice heterozygous for the Pink1 null allele were intercrossed to produce homozygous Pink1 KO mice. Cohorts of Pink1 KO and littermate controls were aged up to 16 months. Pink1 KO mice appeared normal at birth and were indistinguishable from control mice with respect to body weight and femoral length during adulthood. As expected, control mice lost bone mass with age. In contrast to Sirt3 KO mice, however, deletion of Pink1 had no effect on the age-related loss of either cortical or trabecular bone mass of the femur or spine in Pink1 null mice. Likewise, deletion of Pink1 had no effect on RANKL-induced osteoclast formation and the expression of osteoclast markers in cultured bone marrow-derived macrophages. Furthermore, the protein levels of the mitophagy markers Bnip3 and Nix were unaffected by deletion of Pink1 in cultured osteoclasts. These results suggest that PINK1 does not contribute to mitophagic flux in osteoclasts or the development of osteoporosis caused by aging. Based on this evidence, we conclude that PINK1 is dispensable for osteoclast maturation and skeletal involution in mice.

Progranulin inhibits C5a/C5aR1 signaling via direct binding to C5a and its deficiency exaggerates osteoarthritis due to hyper-activation of the complement system *Wenyu Fu[1], Guiwu Huang[1], Chuan-ju Liu[1]. [1]New York University Grossman School of Medicine, United States

The prevalence of osteoarthritis (OA) is increasing globally, with significant economic impacts and negative effects on quality of life. Accumulating evidence demonstrates that complement activation is involved in the pathogenesis of OA, although the molecular events involved remain to be elusive. While previous research has shown that C5 deficiency can attenuate arthritis in mouse OA model, the mechanisms of C5/C5a in OA have not been understood. Our lab has long-standing interest in investigating the role of progranulin (PGRN), a growth factor like molecule, in the pathogenesis of OA. The findings that PGRN bind to cysteine-rich domains (CRDs) of various proteins, together with the fact that complement proteins contain CRDs, suggesting that PGRN may interact with and affect the complement system. We thus conducted solid-phase binding assays to screen the interactions between PGRN and central complement components, including C1-C9, C5a and C3a. Our results showed that PGRN strongly binds to C5 and dose-dependently binds and saturates C5a. Additionally, PGRN/C5a complex formation in mouse sera was confirmed by Co-IP, and PGRN binds to C5a with a high affinity of KD 7.18+/-0.07nM measured by Analytical Surface Plasmon Resonance. Further functional assays demonstrated that PGRN inhibits C5a binding to C5aR1 and effectively blocks C5a binding to cell surfaces, indicating that PGRN acts as a natural antagonist of C5a signaling. PGRN was also found to antagonize C5a's effect on macrophage polarization.ELISA analysis showed a significant increase in C5a levels in the synovial fluid of OA patients than healthy controls, indicating hyperactivation of the complement cascade in OA synovial fluid. PGRN levels were also significantly higher in the synovial fluid of OA patients compared to healthy controls. Furthermore, a positive correlation was found between the levels of PGRN and C5a in OA patients ($r = 0.5475$, $P < 0.0001$). The interaction and interplay of PGRN/C5a were also investigated in vivo using various genetically deficient mice with surgically induced DMM model. The results showed that deletion of C5aR1 partially reversed the exaggerated OA phenotype, including severe cartilage loss and increased OA-associated pain observed in PGRN-/- OA mice. These findings suggest that PGRN interacts with C5a/C5aR1 signaling to regulate macrophage function, and PGRN mitigates OA by suppressing proinflammatory activities of C5a through interrupting C5a/C5aR1 signaling (Fig.1).

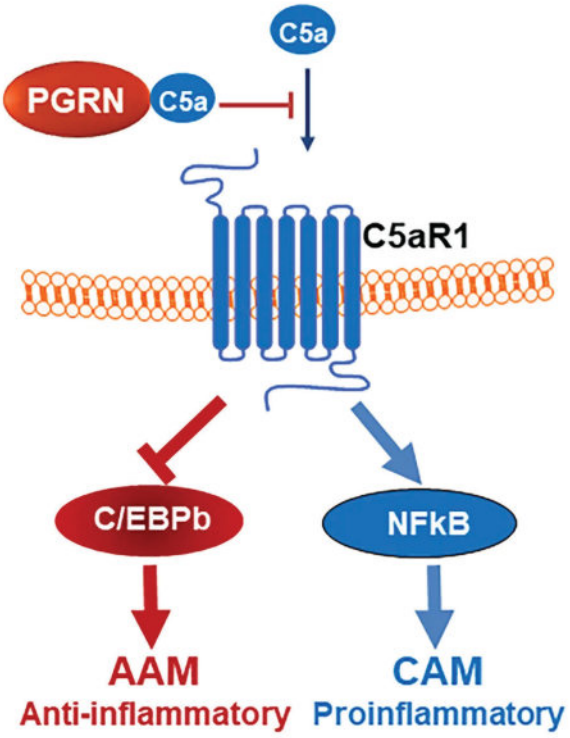

Fig1. A proposed model illustrating the interplays between PGRN and C5a/C5aR1 signaling in regulating macrophage polarization. PGRN directly binds to C5a and inhibits C5a/C5aR1 signaling, and resultant macrophage polarization regulation and OA progression.

Rigorous identification of p21+ and p16+ senescent cells by scRNAseq reveals distinct SASP profiles of these cells in bone and across tissues *Dominik Saul[2], MADISON DOOLITTLE[2], David Monroe[3], Sundeep Khosla[4]. [2]Mayo Clinic, . [2]Mayo Clinic, United States. [3]Mayo Foundation, United States. [4]Mayo Clinic College of Medicine, United States

Cellular senescence has been shown to drive multiple age-associated diseases, and clearance of Cdkn2a (p16)+ cells prevents age-related bone loss in mice (Nat Med, 2017). We recently demonstrated the transient appearance of senescent cells during fracture healing and the importance of Cdkn1a (p21), but not Cdkn2a (p16) in this process (eLife, 2021). Specifically, we found that the clearance of Cdkn1a+ cells accelerated the time course of fracture healing. We have also recently demonstrated the importance of Ki67- and Bcl2+ (KB) cells for age-related bone loss (BioRxiv, 2023). Pairing these mechanistic insights with a senescence/SASP gene set that has recently been established by our group (SenMayo, Nat. commun. 2022), we identified Cd45-, KB cells using scRNAdeq data from bone/bone marrow and found them to highly express the canonical markers of senescence, Cdkn2a (p16) and Cdkn1a (p21) (Panel A, B), with only very few cells showing expression of both markers (Panel C). To further characterize these cells, we analyzed the SASP of the selected p21KB vs. p16KB cells. As shown in panel D, this revealed a largely distinct SASP of the 2 populations in bone/bone marrow cells. To expand these findings to other tissues, we next used this approach to identify the p21KB and p16KB cells in scRNAseq data from skeletal muscle, brain, lung and liver. Similar to findings in bone/bone marrow, the p21+ vs the p16+ cells expressed a largely non-overlapping SASP across tissues. Combining the insights from all tissues, Pecam1, Jun and Sema3f stood out from the p21+ cells as consistently expressed SASP markers (Panel E), while Ccl5 dominated within the p16+ senescent cells. Collectively, our findings demonstrate that p21+ or p16+ senescent cells identified in scRNAseq data using rigorous criteria (expression of Cdkn1a and/or Cdkn2a, growth arrest, upregulation of anti-apoptosis genes) express very different SASP profiles not only in the bone microenvironment, but across multiple tissues. Whether these differing SASP profiles account for

varying contributions of p21+ or p16+ senescent cells in modulating tissue repair vs. aging phenotypes is an important question that needs further studies.

SUN-223

The Mechanism of the Age-dependent Decline in Bone Formation *Irina Tourkova[1], Quitterie Larrouture[2], Kelichi Onwuka[2], Silvia Liu[3], Jianhua Luo[2], Paul Schlesinger[4], Harry Blair[2]. [1]Pittsburgh VA and University of Pittsburgh , United States, [2]University of Pittsburgh, United States, [3]University of Pittsburgh , United States, [4]Washington University in Saint Louis, United States

We studied the effect of age on proteins critical to bone matrix and mineral transport. Non-quantitative studies reported histological effects, in some cases concluding differences in apoptosis. In contrast, we analyzed quantitative expression of genes and proteins involved in bone formation in aged (18-19 month) and young (3-4 month) C57 black mice. We compared results using cells flushed from femur and tibia in vivo and, for the first time, osteoblasts differentiated from Stromal Stem Cells (SSC) on polyethylene terphthalate (PET) membranes in vitro. Apoptosis did not occur in vitro in bone differentiated from SSC on PET membranes using young or old cells. Age correlated with reduced in mRNAs of mineral transport proteins, alkaline phosphatase (ALP), ankylosis (ANK), and the Cl-/H+ exchanger ClC3. Results were similar in vivo and in vitro. For bone matrix proteins, COL1 and osteocalcin, expression was, as expected, also significantly reduced with age. µCT analysis of lumbar vertebrae showed that trabecular bone of the 18-19 month mice is osteopenic relative to the 3-4 month mice. Additional novel work used gene array analysis to compare osteoblasts differentiated on PET membranes from young and old mice. Results were consistent with known bone formation-related proteins, but we also found additionally major reduction in the pyrophosphatase/phosphodiesterase ENPP2 with age. Since ENPP2 was not previously related to mineral formation, we used silencing ENPP2 with RNAi duplexes to show down-regulation of osteoblast ALP activity and mineralization. In this work, ENPP2 RNAi duplex transfection was documented by fluorescence (Figure, panel A) and real time PCR (Panel B). Decreased osteoblast differentiation was shown by ALP and Alizarin Red (Panel C). Real-time PCR of SSCs differentiated into osteoblasts for 2 weeks confirmed decline in ENPP2 and ALP in transfected cells (Panel D). Further, we analyzed pathways of osteoblast differentiation in vitro on PET membranes. This revealed that cells from older animals had reduced Erk1/2 phosphorylation, decreased SMAD 2 mRNA, consistent with TGF-? pathway regulation, and reduced ?-catenin mRNA and protein consistent with changes in the WNT pathway. Our results suggest that decline in trabecular bone structure reflects, at least in part, reduced osteoblast differentiation and decrease of matrix and mineral transport proteins with age involving multiple signaling pathways.

Senescence features in pre-malignant plasma cells are associated with stable disease in MGUS and SMM *GABRIEL ALVARES BORGES[1], ANGELO GUILATCO[2], CHRISTINE HACHFELD[3], MING XU[4], FATIMA MUSTAPHA[5], MARTA DIAZ-DELCASTILLO[5], Thomas Andersen[6], TAXIARCHIS KOURELIS[3], TAMAR TCHKONIA[3], JAMES KIRKLAND[3], MATTHEW DRAKE[3], Megan Weivoda[3]. [1], [2]Mayo Clinic/University of Michigan, [3]Mayo Clinic, United States, [4]University of Connecticut, United States, [5]Aarhus University Hospital, Denmark, [6]University of Southern Denmark, Denmark

Multiple myeloma (MM) is a clonal plasma cell (PC) malignancy that progresses from monoclonal gammopathy of undetermined significance (MGUS) and/or smoldering MM (SMM) at rates of 1% and 10% per year, respectively. Despite similar primary genetic abnormalities as MM, MGUS and SMM are non-proliferative, and the mechanisms for disease progression remain unknown. Since oncogenes and DNA damage drive senescence growth arrest, we hypothesized that MGUS and SMM PCs could exhibit senescence features. Differential expression analysis of MGUS and SMM PCs compared to normal (GSE5900) revealed significant increases in the senescence markers CDKN1A and GADD45A. Gene set enrichment analysis showed that MGUS PCs had significant enrichment of senescence phenotyping gene sets that were distinct from aging. We next assessed morphological features of senescence, including the loss of LaminB1 (LoL) and senescence associated distension of satellites (SADS), in MGUS, SMM, and MM PCs, followed by senescence gene expression analysis. PCs from patients with stable MGUS (N=4) exhibited increased number of SADS+ PCs with LoL compared to SMM and MM patient PCs. When SMM PCs were evaluated based on progression (stable vs progressed <=5 years, n=6-8), there remained no differences in SADS or LoL. Despite this, stable SMM patient PCs, but not those from progressors, had increased expression of senescence genes, including CDKN1B, CDKN2A, CDKN2B, TP53, BCL2, and IL1B compared to MGUS PCs. Both stable MGUS and SMM patient PCs showed a significant increase in the expression of the retrotransposable element LINE1, which is increased with senescence, compared to PCs from SMM progressors and MM patients. Overall, our results demonstrate the presence of stage-specific senescence features in PCs from stable MGUS and SMM patients; these senescence features are decreased in PCs from SMM progressors and MM. These findings are consistent with the protective effect of senescence against tumorigenesis. Thus, evaluating PC senescence in MGUS and SMM may have prognostic value to identify patients at risk for progression to MM. Importantly, however, given that stable MGUS patients are at increased risk for osteoporotic fracture and have reduced overall survival due to aging co-morbidities, the senescence-related protection against MM may come at the expense of premature aging. Ongoing studies are evaluating the safety and therapeutic utility of ablating pre-malignant senescent cells in MGUS and SMM.

SUN-226

The Role of cped1 in the Zebrafish Axial and Craniofacial Skeleton *Kurtis Alvarado[2], Ronald Kwon[2], W. Joyce Tang[2], Claire J. Watson[2], David Karasik[3], Donaka Rajashekar[3]. [2]University of Washington, [2]University of Washington, United States, [3]Bar-Ilan University, Israel

Genome wide association studies have identified 7q31.31, also known as the CPED1-WNT16 locus, as a key region harboring genetic variants associated with bone-related traits. These traits include bone mineral density (BMD) in the spine, femoral neck, and skull, as well as facial shape [1,2,3]. It has been speculated that multiple causal genes might underlie genetic effects at the CPED1-WNT16 BMD locus [4]. While knockout studies in mice show Wnt16 is an important regulator of bone structure and strength, little is known about the role of Cped1 in the skeleton. We hypothesized that cped1 contributes to vertebral bone mass and mineralization and craniofacial morphology in adult zebrafish. To test this, we used two mutant lines: cped1w1003 (c.831-844delinsACT), which we have previously described [4], and cped1sa20221 (c.1922 C>A). Both alleles are predicted to lead to a premature stop codon and early truncation of the protein. For analysis, adult 3-month old zebrafish were scanned using microCT, and ImageJ and FishCuT software were utilized to measure vertebral morphology and mineralization. Craniofacial morphology was assessed in SlicerMorph using manual landmarking as we have previously described [5]. RT-PCR revealed a reduction in cped1 transcript levels in cped1sa20221 mutants, supporting cped1 loss of function. Vertebral analysis revealed no significant differences between homozygous mutants and wildtype controls for all traits (Volume, Thickness, Length, and Tissue Mineral Density) and compartments (Neural Arch, Centrum, Haemal Arch) measured for both mutant alleles (w1003: n=8/group; sa20221: n=8/group). Craniofacial analysis revealed cped1w1003 mutants exhibited a significant decrease in skull width (p=0.0206; n=6-7/group); however, no significant difference in this trait was observed for cped1sa20221 mutants (n=7/group). We found little evidence that cped1 contributes to vertebral bone mass and mineralization or craniofacial morphology in adult zebrafish. It is possible zebrafish and mouse orthologs for CPED1 have distinct functions, or that loss of the zebrafish ortholog is compensated for by other genes. Thus, Cped1 knockout studies in mice are needed to better understand the potential for CPED1 to act as a causative gene underlying effects at 7q31.31 on bone-related traits.1. Phenotypic characterization of mice lacking Piezo1 and/or Piezo2 in Col2a1-expressing cells *Laura J Brylka[1], Miriam EA Tschaffon-Müller[2], Simon von Kroge[1], Astrid Schoppa[2], Melanie Haffner-Luntzer[2], Kian M Eghbalian[1], Eva Pawlus[1], Timur A Yorgan[1], Michael Amling[1], Anita Ignatius[2], Thorsten Schinke[1]. [1]University Medical Center Hamburg-Eppendorf, Germany; [2]University Medical Center Ulm, Germany

Piezo proteins function as mechanotransducers in several organ systems including bone. We and others have reported that Piezo1 in osteocytes mediates the bone-anabolic response after mechanical stimulation in vivo. Our analysis of conditional mouse models also indicated that Piezo1 expression in chondrocytes is required for trabecular bone formation below the growth plate. To further analyze the role of Piezo proteins in endochondral ossification, we studied the phenotype of mice lacking Piezo1 and/or Piezo2 in Col2a1-expressing cells.Piezo1Col2a1cre, Piezo2Col2a1cre and Piezo1,2Col2a1cre mice and their Cre-negative littermates were analyzed at different ages using contact radiography, micro-computed tomography (µCT) and bone histomorphometry. While longitudinal bone growth and growth plate thickness were only moderately affected in Piezo1Col2a1cre mice, trabecular bone formation below the growth plate was strongly affected starting from postnatal day 7 (P7, BV/TV in lumbar spine: 9.2 +/- 3.7% vs. 14.0 +/- 2.5% in controls; P14: 5.4 +/- 1.8% vs. 13.2 +/- 2.8% in controls). In addition, Piezo1Col2a1cre mice showed multiple rib bone fractures, most of which occurred in the first week after birth (P7, rib fractures per mouse: 12.9 +/- 3.8). This is possibly explained by a reduced cortical thickness (Ct.Th: 13.5 +/- 1.0 µm vs. 16.1 +/- 1.4 µm in controls) and trabecular bone volume fraction (BV/TV: 9.9 +/- 2.2% vs. 13.8 vs. 3.3%) in ribs of newborn mice, as measured by high-resolution µCT. The skeletal phenotype of Piezo1/2Col2a1cre at P21 was similar to that of Piezo1Col2a1cre mice, while Piezo2Col2a1cre mice had a normal skeletal phenotype.We also performed in vitro transcriptome analyses using ATDC5 and MC3T3-E1 cells to detect novel Piezo1 downstream targets by treating the cells with the Piezo1 agonist Yoda1, or applying mechanical stimulation using laminar fluid flow. We observed the induction of the known target gene Ptgs2, but also other genes such as Ccn2, which is expressed by hypertrophic chondrocytes and essential for endochondral ossification.Our data show that deficiency of Piezo1, but not of Piezo2 strongly affects the formation of trabecular bone below the growth plate, indicating a role for Piezo1 in chondrocyte-to-osteoblast transdifferentiation. It remains to be studied whether Ccn2 or other Yoda1-induced genes are relevant downstream mediators of Piezo1 function in endochondral ossification.

Mutations in efemp1 cause changes to bone mass and mineralization in adult zebrafish *Arianna Ericka Gomez[1], Rohda Yase[2], Yi-Hsiang Hsu[3], Ronald Kwon[1]. [1]University of Washington, United States; [2]University of Washington Seattle, ; [3]HSL Institute for Aging Research, Harvard Medical School, United States

EFEMP1 is a member of the fibulin family of extracellular matrix glycoproteins. Several studies have identified EFEMP1 as a biomarker for osteoarthritis and variants in the EFEMP1 gene are linked to connective tissue conditions [1-4]. In mice, Efemp1 is expressed in developing bone and cartilage, and has been found to negatively regulate chondrocyte differentiation in a carcinoma-derived chondrogenic line [5-6]. While multiple studies indicate that Efemp1 is expressed in osteoblasts and their progenitors, animal knockout studies rigorously examining its role in the skeleton are lacking. We hypothesize that efemp1 regulates acquisition of adult bone mass and mineralization in zebrafish. To test this, we used CRISPR0based gene editing to isolate 3 efemp1 mutant lines with deletions in exon 4, and whose alleles are designated as w1014 (8bp deletion), w1016 (13bp deletion), and w1017 (4bp deletion). All three alleles result in premature stop codons predicted to result in nonsense-mediated decay and severe truncation of the protein; therefore, they are predicted to functionally act as null mutants. In preliminary analyses, mutants for all three alleles exhibited similar phenotypic trends and thus we refer to all three mutants as efemp1-/-. MicroCT analysis of 90 day post fertilization (dpf) adult fish revealed that efemp1-/- fish exhibited significantly ($p<0.05$, n= 24 - 30/group) increased centrum volume, tissue mineral density, and thickness, and increased neural arch volume, compared to wildtype controls. Moreover, efemp1-/- mutants exhibited a trend ($p=0.10$) towards having increased standard lengths. efemp1-/- mutants exhibited significant differences in traits following allometric normalization for standard length [7], suggesting that phenotypic differences in efemp1-/- mutants were not solely attributable to differences in developmental progress. Our studies suggest that loss of efemp1 positively influences acquisition of bone mass and mineralization in adult zebrafish. Understanding the role of efemp1 in bone can advance our understanding of genetic influence on skeletal traits and identify a new therapeutic target for osteoporosis.[1] Hasegawa, A. et al. 2017. Limb-specific loss-of-function of Prrx1 identifies roles in postnatal skeletal morphogenesis and short-stature signalling pathways *Michael Kluppel[2], Sai Rama Krishna Meka[2], Anna Spagnoli[2], Alessandra Esposito[3], Pranav Mishra[4], Huseyin Ozkan[2], Esin Ozkan[2]. [2]Rush University Medical Center, United States; [2]Rush University Medical Center, ; [3]University of Chicago, ; [4]Rush University,

Background.A global knockout (KO) of the Paired Related Homeobox 1 (Prrx1) gene in mice has previously been shown to lead to perinatal lethality and skeletal abnormalities. In order to prevent the early lethality and assess the roles of Prrx1 in postnatal life, we generated a conditional Prrx1 loss-of-function allele and assessed its effects in postnatal skeletal development and morphogenesis as well as human short-stature signaling pathways.Methods.We generated a mouse strain carrying a floxed Prrx1 allele and crossed these mice with a previously described driver strain in which Cre is expressed under the control of a 2.4kb limb mesenchyme enhancer of Prrx1 (Prrx1-2.4kb enhancer). The skeleton at 4 weeks after birth was assessed using Alcian Blue-Alizarin Red skeletal stains as well as X-Rays and uCT analysis. The role of Prrx1 in regulation of SHOX expression was analyzed by luciferase assays. Data are expressed as mean +/- SD.Results.Prrx1 conditional homozygous mutants survived into adulthood and were fertile. Alcian Blue-Alizarin Red skeletal stains as well as X-Ray and uCT analysis of homozygous Prrx1 mutants showed shortened, thickened, and flattened zeugopod bones in both fore- and hindlimb. The radius also showed significant bowing, and the typical fusion of the distal tibia and fibula observed in wild type mice in the hindlimb was absent in mutants. In addition, the wrist showed morphogenesis defects similar to human Madelung deformity, including altered orientation of specific carpal bones. In the hindlimb, morphogenesis of the calcaneus was altered. Moreover, the skull lacked suture fusion and closure. Quantitative X-Ray analysis demonstrated that forelimb zeugopod length in mutants at 4 weeks of age was reduced to 45.5% +/- 9.6% in males and 43.9% +/- 4.1% in females. Hindlimb tibia length was reduced to 83.3% +/- 7.4% in males and 87.4% +/- 1.1% in females. Since Madelung wrist malformations have been shown to be associated with mutations in enhancers of the short-stature homeobox gene SHOX in humans, we performed preliminary luciferase assays which showed that Prrx1 can positively regulate a transcriptional regulatory element of SHOX mutated in human short-stature patients.Conclusion.Our results demonstrate that Prrx1 plays a critical role in zeugopod bone morphogenesis as well as wrist and ankle formation. Furthermore, our data indicate a mechanistic role for Prrx1 in the regulation of critical regulators of bone formation, including SHOX genes.

CRISPR/Cas9 based knockout of sox6 gene severely affects the musculoskeletal health and aging rate in zebrafish *Donaka Rajashekar[1], David Karasik[1], David Karasik[2]. [1]The Azrieli Faculty of Medicine, Bar-Ilan University, Israel; [2]Hebrew SeniorLife, Hinda and Arthur Marcus Institute for Aging Research, Boston, MA, USA., United States

Aging of human musculoskeletal (MSK) traits is linked to many vital functions, disability, frailty, and ultimately survival. Functional integrity of bone and muscle tissues can be achieved via shared molecular signaling pathways. Genetics exert a significant role in losses of both bone and muscle mass and function. Genome wide association studies (GWAS) have discovered multiple candidate genes for age-related MSK traits, including BMD at the lumbar spine and femoral neck. Among them, SOX6 is suggested as one of the strong candidates for its potential association with bone metabolism. Modeling of human disease by knocking-out (KO) sox6 gene in zebrafish (ZF) could aid in discovering potential drug targets or biomarkers for MSK system's aging.KO of sox6 gene in ZF was done by CRISPR/Cas9 technology. In young adult ZF, body weight and length were measured, while swimming performance was determined by 3 min video recordings (n=12 animals per group, KO and wild-type, WT). A cellular senescence (SA-beta-gal) assay was applied at regenerated caudal fins. Expression of selected genes in caudal fins was measured by RT-qPCR. Using micro-CT SKYSCAN 1172 (Bruker), BMD of head bones was measured, and hematoxylin and eosin staining performed for muscle histology (n=8). Deletion of 11 base pairs in sox6 gene had been confirmed by DNA sequencing, and absence of sox6 protein was shown by Western blot. In-crossing of homozygous mutants revealed complications in their reproductive system by producing lower ($p=0.04$) number of eggs than WT. During skeletal growth, sox6-/- (KO) fish had a significant reduction in total body length and weight (both $p<0.0001$) compared to WT siblings. Further, sox6-/- fish had demonstrated slower movement ($p=0.0004$) that resembles of seahorse swimming pattern. Alterations in skeletal muscle fibers morphology were apparent at dorsal and trunk region of sox6-/- adult zebrafish compared to WT siblings. Micro-CT imaging had shown disorganized head bones in sox6-/- (Fig1). A cellular senescence assay had indicated a higher SA-beta-gal; increased expression of cyclin dependent kinase inhibitors (cdkn1a and cdk2ab) in sox6 KO at caudal fins on 4th day of regeneration. This progeric phenotype corresponded to an early death in sox6-/- ZF (max. survival: 7 months and 15 days; log-rank test, $p=0.03$).Knockout of sox6 gene activates premature aging with deterioration of the functional integrity of bone and muscle tissues.

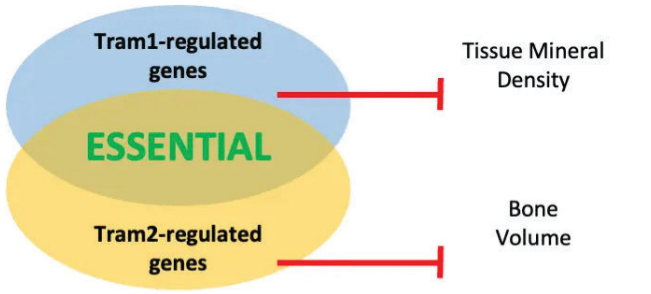
Translocation Genes tram1 and tram2 Regulate Bone Mass and Mineralization *Kiana Reynolds[4,] Joyce Tang[2,] Anne Onyali[2,] Jyoti Rai[2,] Arianna Gómez[2,] Claire Watson[2,] Yi-Hsiang Hsu[3,] Ronald Kwon[4,] [4]University of Washington, [,2]Department of Orthopaedics and Sports Medicine, University of Washington School of Medicine, Seattle, WA, USA, United States, [3]Institute for Aging Research, Hebrew SeniorLife, United States, [4]University of Washington, United States

Osteoporosis is characterized by decreased bone mineral density (BMD) and increased bone fragility, putting patients at higher risk for fractures. Genome-wide association studies (GWAS) have identified loci harboring genetic variants associated with osteoporosis-related traits. One such locus is the XKR9 locus associated with BMD. The XKR9 locus comprises several genes, and the causal gene at the locus is currently unknown. Here, we examine the skeletal functions of TRAM1, a gene in proximity to XKR9, and TRAM2, a homolog of TRAM1. TRAM1 plays an important role in stabilizing proteins during translocation into the endoplasmic reticulum lumen [1]. Though the function of TRAM2 is not well characterized, it is suggested to play a role in collagen translocation [2]. Currently, no in vivo knockout studies have been published investigating the TRAM genes. We hypothesized that tram1 and tram2 are necessary for adult bone mass and mineralization in zebrafish. To test this, we used CRISPR-based gene editing to isolate tram1w1007 and tram2w1005 zebrafish germline mutants. We also generated tram1w1007;tram2w1005 compound mutants. MicroCT scans were generated at 90 days post fertilization, and ImageJ and FishCuT were used to quantify the impacts on vertebral bone morphology and mineralization. tram1 mutants exhibited significant increases in tissue mineral density (TMD) (centrum TMD, p= 0.0402; haemal arch TMD, p=0.0332; neural arch TMD, p=0.0335; n=13/group) while tram2 mutants showed significant increases in centrum and neural arch volume (centrum volume, p=0.0392; neural arch volume, p=0.0031; n=11/group). Additionally, fish with homozygous mutations in tram1 and heterozygous in tram2 (n=19) showed no significant changes compared to controls (n=5), however tram1;tram2 double mutants exhibited lethality at the larval stage. These findings identify overlapping and distinct roles for tram genes in vivo (Fig. 1). They also provide evidence that variants at XKR9 could act through TRAM1 to influence BMD thereby introducing translocation as an important factor underlying genetic influence on osteoporosis risk.References1. Hegde et al., 2008, J Cell Biol; 2. Stefanovic et al., 2004, Mol Cell Bio.



Genotype	Phenotype

Investigating the Effects of Antipsychotics on Embryonic Bone Development *Kavindi Weerasinghe[1,] Alister Ward[2,] Clifford Liongue[2,] Jason Hodge[2,] Julie Pasco[2,] Rasika Samarasinghe[2,] Lana Williams[2,] [1]PhD student, Australia, [2]Supervisor, Australia

Antipsychotics are the first line treatment in schizophrenia, a condition involving dysregulation of multiple neurotransmitters including dopamine, serotonin, noradrenaline, histamine and muscarinic pathways. Evidence has shown antipsychotic use decreases bone mineral density and increases fracture risk in adults, with dopamine, serotonin and adrenergic receptors previously been found in bone cells in vitro. Use of antipsychotics during pregnancy, particularly second-generation agents has increased. To date there is no clear evidence of the impact on fetal bone development. Therefore, we aimed to investigate the effects of antipsychotics on embryonic bone formation in-vivo using a zebra fish model. MethodsThe effect of first (chlorpromazine and haloperidol; FGAs), second (olanzapine and quetiapine; SGAs) and third (aripiprazole; TGA) generation antipsychotics on early zebrafish bone development was measured using alizarin red staining. Osteoblasts development marker expression was measured using whole mount in-situ hybridisation method followed by dopamine, serotonin and adrenergic receptor expression profile along with apoptosis studies.ResultsEach antipsychotic dose-dependently inhibited zebrafish bone formation. The FGAs, chlorpromazine and haloperidol, both inhibited bone development at IC50 ~23 ?M and ~3 ?M, respectively. Whereas the SGAs, olanzapine and quetiapine inhibited bone development at IC50 ~73 ?M and ~54 ?M respectively. Aripiprazole, a TGA, inhibited bone development at IC50 ~9 ?M. Expression of osteoblast genes runx2b, col10a and spp1 were reduced with the treatment of 10 µM for FGAs and TGA, where SGAs reduced the bone development with 30 µM demonstrating that these agents are affecting the in-vivo bone development in zebrafish embryos.ConclusionAll tested antipsychotics dose dependently inhibited zebrafish embryos bone development, where FGAs and TGAs were the most potent inhibitors compared to SGAs. This raises further questions regarding the short and long-term effects on bone health of offspring, with future research into dopamine, serotonin and adrenergic signalling pathways to further understand the mechanisms of action.

Elevated PDGFR? Signaling Causes Knee Joint Fusion by Disrupting Synovial Progenitor Differentiation *John Woods[1,] Lorin Olson[1,] [1]Oklahoma Medical Research Foundation, United States

Mouse knee joint development begins at E11.5-E13.5 when a cartilage template is divided in two by the formation of an interzone, an anlage that gives rise to all the structures of a mature joint. Before interzone formation, the cartilage template expresses cartilage genes Sox9 and Col2a1. These genes are downregulated upon interzone formation and replaced by Gdf5, a member of the bone morphogenic protein family. Platelet-derived growth factor receptor-? (PDGFR?) is not expressed in the cartilage template of the limb, but it is expressed in the perichondral mesenchyme and Gdf5+ interzone cells. Based on this expression pattern, we hypothesized that tight regulation of PDGFR? signaling may be crucial for joint development. To investigate this role of PDGFR?, we used gain-of-function (?GOF) and loss-of-function approaches with Prx1-Cre, which is active in the early limb bud mesenchyme. Loss-of-function did not affect joint formation. However, ?GOF mice were born with knee

joints fused by ectopic cartilage and lacking ligaments and menisci. Interzone specification occurred normally in ?GOF mutants up to E13.5, but Gdf5 expression was decreased. Further, there was expansion of Sox9 protein expression into domains that are normally Sox9-negative. These results suggest that elevated PDGFR? signaling interferes with joint progenitor differentiation by redirecting Gdf5+ interzone cells from a synovial connective tissue fate to a Sox9+ chondrogenic fate. Thus, PDGFR? signaling has pro-chondrogenic properties that must be tightly regulated to allow differentiation of ligaments, menisci, and other connective tissue cell types. This property of PDGFR? signaling may be important in other contexts such as de novo cartilage formation in fracture healing.

Understanding CXXC Finger Protein 1 Action in Osteoblast Differentiation
*Ahmed Al Saedi[1], Katelyn Healey[2], Molly Persky[2], David Maridas[3], Lijie Jiang[2], Vicki Rosen[3], Diana Carlone[4]. [1]Department of Pediatrics, Harvard Medical School and Division of Endocrinology, Boston Children's Hospital, United States. [2]Division of Endocrinology, Boston Children's Hospital, United States. [3]Harvard School of Dental Medicine, United States. [4]Boston Children's Hospital, United States

Skeletal development, remodeling and regeneration are dependent on the activity of mesenchymal progenitor cells (MPCs). Recent data have implicated epigenetics in the regulation of MPC function with links to altered bone formation in both mice and humans. Precisely how epigenetics controls MPC activity and function, including the ability of MPCs to participate in bone formation, remains less clear. Here, we focus on CXXC Finger Protein 1 (CFP1), an epigenetic regulatory factor that mediates transcriptional activation through targeted H3-Lys4 methylation of chromatin. While CFP1 has been identified as a regulator of progenitor cell differentiation in other systems, its role in bone formation remains to be defined. To address this, we deleted Cfp1 in MPCs using Prx1-Cre (cKOPrx1), which resulted in halted chondrocyte differentiation, maturation and primary ossification, implicating this factor as a critical regulator of endochondral ossification. In addition, a decrease in intramembranous ossification within the calvaria was detected in mutant mice consistent with a role for CFP1 as a direct regulator of osteoblast differentiation. To investigate this further, we performed adenoviral deletion of Cfp1 in bone marrow stromal cells (BMSCs) isolated from homozygous floxed-Cfp1 mice. Quantitative RT-PCR (qPCR) analysis revealed a dramatic reduction in the expression of osteoblast markers (Runx2, Osx, Col1a1, Ocn) supporting a role for Cfp1 in bone formation. To further define its role in osteoblast differentiation, we generated Cfp1 knockout MC3T3-E1 cells using CRISPR/Cas9 and mice using Osx1-Cre (cKOOsx1). Studies investigating if changes in osteoblast differentiation occur in the absence of Cfp1 are currently underway. In summary, our recent findings link CFP1 action to both endochondral and intramembranous bone formation.

The Role of EGF Containing Fibulin Extracellular Matrix Protein 1 (Efemp1) in Skeletal Development
*Rohda Ahmed Yase[1], Arianna Ericka Gòmez[1], Yi-Hsiang Hsu[2], Ronald Young Kwon[1]. [1]University of Washington Seattle, United States. [2]HSL Institute for Aging Research, Harvard Medical School, United States

EFEMP1 is a member of the fibulin family which encodes an extracellular matrix (ECM) glycoprotein that is expressed in epithelial cells and elastic-fiber-rich tissues. Previous studies in mice show that Efemp1 is expressed in the sclerotome, an embryonic unit that gives rise to bone structures of the axial skeleton. However, the role of EFEMP1 in skeletal development is poorly understood. In this study, we tested the hypothesis that efemp1 is necessary for axial skeletal development in zebrafish. Using CRISPR-based gene editing, we isolated zebrafish germline mutants with an 8 base pair deletion (efemp1w1014), 13 base pair deletion (efemp1w1016), and 21 base pair deletion (efemp1w1015) in exon 4. Whereas efemp1w1014 and efemp1w1016 result in premature stop codons which are predicted to induce loss-of-function in efemp1, efemp1w1015 is an in-frame mutation resulting 7 amino acid deletion. To determine the role of efemp1 in spine development, we analyzed 13 days post-fertilization (dpf) efemp1w1014, efemp1w1015, efemp1w1016 mutants stained with calcein, which binds to actively mineralizing structures. The area of mineralizing vertebrae was measured using FIJI and statistical analyses were performed using Graphpad. We found no significant differences in vertebral mineralized area when comparing homozygous mutants and wildtype controls for efemp1w1014 (n=5-10) and efemp1w1016 (n=7-8). We found a trend (p=0.06) toward decreased vertebral mineralized area for efemp1w1015 mutants (n=4-7). Our results indicate that efemp1 may play a role in spine mineralization. Specifically, whereas mutations predicted to result in loss of Efemp1 (w1014 and w1016) can potentially be compensated for, a mutation predicted to alter Efemp1 protein structure (w1015) appears to result in impaired mineralization. By understanding the role of efemp1 in spine development, we will better understand the role of fibulins in skeletal development and their influence on skeletal traits.

Can early hip fracture surgery improve physical function following fragility fracture in elderly patients with osteoporosis?
*Jun Hwan Choi[1], Soyeon Yoo[2]. [1]Department of Rehabilitation Medicine, Jeju National University Hospital, Republic of Korea. [2]Department of Internal Medicine, Jeju National University Hospital, Republic of Korea

Background and aims: Hip fractures are the most serious osteoporosis-related fracture. Most patients who have had hip fracture surgery do not return to their previous level of function. Although there are studies on the association between early surgery and mortality after hip fracture, there are few studies on the functional prognosis of early surgery. The purpose of this study was to investigate the relations between timing of hip fracture surgery and physical function following fragility fracture in elderly patients. Methods: The patients who underwent hip fracture surgery between January 2019 and December 2022 were retrospectively enrolled through a cohort study. From the cohort data, we only selected patients with a first diagnosis of hip fracture, and excluded patients with acceptable reasons for delay, such as uncorrectable or correctable medical problems and cognitive impairment. Of the 223 patients with fragility hip fracture, 59 patients (12 males, 47 females, mean age 78.6 +/- 11.7) met the study enrollment criteria. Patients were divided into two groups: within 48 hours from arrival at the emergency room to surgery (early surgery group, N=24) or not (delayed surgery group, N=35). All functional outcomes were assessed at the beginning and discharge of in-patient rehabilitation and at 3 months after surgery. The Koval's grade, performance-based physical function (10-meter walk test, timed up and go, Berg balance scale) Results: There was no significant difference between the two groups in the demographic characteristics and type of surgery, and fracture site and side. The mean surgical timing of early surgery group is 35.7 +/- 10.7 hours and delayed surgery group is 85.0 +/- 40.7 hours. The early surgery group had significantly higher level of balance and gait speed at the 3 months after surgery. Conclusions: This study demonstrated that hip fracture surgery within 48 hours of admission is associated with better physical function following fragility hip fracture in elderly patients. Patients who do not require medical stabilization should undergo surgery as soon as possible.

Table. Performance-based physical function at beginning and at discharge after hip fracture surgery

Variables	Early surgery group (n=24)	Delayed surgery group (n=35)	*p*-value
Pre-Koval's grade	1.83 ± 1.27	2.11 ± 1.71	0.497

Digit Tip Regeneration is Dependent on Mechanical Load and not Innervation
*Connor Dolan[3], Alyssa Falck[3], KIRBY M. SHERMAN[2], Regina Brunauer[3], Dana Gaddy[4], Larry Suva[5], Lindsay Dawson[6], Ken Muneoka[3]. [3]Texas A&M University, . [2]Texas A&M University , . [3]Texas A&M University, United States. [4]College of Veterinary Medicine, Texas A&M University, United States. [5]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States. [6]Texas A&M University College of Veterinary Medicine, United States

The regenerating mouse digit tip and the human fingertip are mammalian models for epimorphic regeneration, and limb denervation in mice inhibits this response. However, limb denervation also causes severe paralysis, impairs appendage use and diminishes mechanical loading of the denervated tissues. Thus, it is unclear whether the regeneration response requires innervation, mechanical load, or both. Herein, we investigated the role of denervation versus mechanical load during mouse digit tip regeneration.To test the specific role of innervation on digit tip regeneration we surgically denervated individual digits to avoid negatively impacting mechanical loading. To test the specific role of mechanical loading, mice were hindlimb unloaded (HU) during regeneration. For both denervation and HU experiments, regeneration was analyzed using in vivo microCT (uCT) to quantify bone volume

and length, and samples were collected throughout for histological and immunohistological quantification of wound closure, blastema formation, osteoclast resorption and proliferation. For all studies, female, 8-week-old CD1 mice were used.Regeneration of sham-operated control digits is completed within 28 days post-amputation (DPA) whereas regeneration of denervated digits is not complete until 42 DPA. The delay in regeneration is not attributed to re-innervation of the digit but is caused by a delayed wound healing response. Treating denervated-digits with Dermabond, a well-established wound dressing, restores wound healing resulting in a restoration of regeneration rate compared to sham-controls digit at 28DPA. Unlike denervation experiments, regeneration was completely inhibited while animals were in HU. At 28DPA, HU-digits were smaller by both bone volume and length, exhibited no histological evidence of blastema formation, had increased osteoclast resorption, and the original amputation wound remained open. Moreover, we also found that removing animals from HU rescues the regeneration response, whereas placing animals in HU during blastema formation attenuates regeneration.Here we show that denervation results in a regeneration response indicating that mouse digit tip regeneration is nerve-independent. In contrast, reducing mechanical loading by hindlimb unloading completely inhibits digit tip regeneration. These studies demonstrate, for the first time, that epimorphic regeneration in mammals requires mechanical load and is independent of innervation.

Development of a novel inorganic polyphosphate-releasing thermoresponsive hydrogel to improve fracture healing outcomes *Rayan BenLetaifa[1,] Deepak Chauhan[2,] Chang-sheng Wang[2,] Hu Zhang[2,] Tarek Klaylat[1,] Derek Rosenzweig[1,] Paul Martinaeu[1,] Xavier Banquy[2,] Rahul Gawri[1.] [1]McGill University, Canada, [2]Universite de Montreal, Canada

INTRODUCTION: Bone fractures are among the most common musculoskeletal injuries. Immune cells play a crucial role in fracture healing, and dysregulation of their function can lead to impaired healing. Inorganic polyphosphates (polyP) have been shown to modulate immune function by closely regulating their functions. At the fracture site, polyPs released by degranulating platelets play a crucial role in initiating coagulation and recruiting immune cells. The objective of the study is to develop a thermosensitive hydrogel with sustained release of polyP to be implanted at the site of fracture to enhance the homing of immune cells.METHODS: Hydrogel formulations and sol-to-gel transition times were tested using several poloxamers, Gellan gum, and poly-N-vinyl-caprolactone (PNVCL). Drug loading of hydrogel formulations was accomplished by mixing dehydrated polymer components with polyP-45-containing distilled water, and supernatant samples were taken at designated time points. Rheological assessments were performed to characterize the viscoelastic properties of the hydrogel. Assays for cell adhesion, cell proliferation, cell survival, and cellular metabolic state to assess the cytocompatibility of the fabricated hydrogel were performed using RBL-2H3 cells, MC3T3 cells, and primary murine BMSCs.RESULTS: The hydrogel formulation consisting of 20% PF-108, 1.5% PNVCL, and 3% Gellan gum (w/v) showed a sol-to-gel transition time of 60 seconds. This formulation was chosen for further analyses and development for its sol-to-gel transition time. polyP release study showed a release concentration of 84.5 μM during the rapid-release phase and maintained a concentration of approximately 37 μM during the extended-release phase. Rheological analyses showed a significantly greater elastic modulus than a viscous modulus. Furthermore, the temperature sweep reveals that the sol-to-gel transition occurs at 35°C. The seeded on the hydrogel showed 92% cell adhesion and 95% cell viability (RBL-2H3, MC3T3, and primary BMSCs).DISCUSSION: This study will generate a novel drug delivery system augmented with a bioactive compound, serving to modulate the body's own immune system to enhance bone healing, improve clinical outcomes, and reduce clinical strain.Finally, after the exhaustion of polyP from the hydrogel, the hydrogel remaining at the site can act as a bio-scaffold, allowing cells to migrate and enhance the development of the fracture callus, thus serving as a dual-purpose bioscaffold.

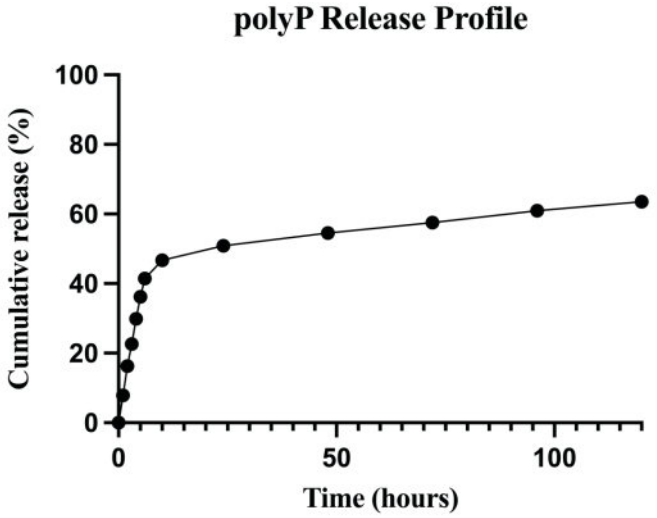

Figure 1: Cumulative release of polyP-45 from hydrogel formulation comprising 20% PF-108 (w/v), 1.5% PNVCL (w/v), 3% Gellan gum. Hydrogel formulation exhibits rapid release during the first 12 hours, releasing approximately 50% of loaded polyP content, and sustained release over the course of 5 days with approximately 65% of polyP being release cumulatively.

New possible pharmacotherapy for osteoarthritis: focus on inflammation and cartilage recover *Fabiana Guerra[1,] Seng Manivong[2,] Elie Joe Mikhael[2,] Pierre Sirois[3,] Xavier Banquy[2,] V. Gaëlle Roullin[2,] Patricia Fernandes[1,] Florina Moldovan[2.] [1]Federal University of Rio de Janeiro, Brazil, [2]Universite de Montreal, Canada, [3]Laval University, Canada

Osteoarthritis (OA) is degenerative joint disease characterized by cartilage degradation, joint pain, subchondral bone turnover changes and synovial inflammation, and without curative treatment.1 Our laboratory has previously shown that the synergistic inhibition of endothelin-1 (ETA) and bradykinin (BKB1) receptors, by BQ123 and R954 antagonist peptides respectively, decrease pain and prevent cartilage degradation in an OA rat model.2 The primary objective of this study was to investigate the potential of the concomitant inhibition of the two GPC-receptors (ETA and BKB1) to reduce the inflammatory process in OA; the second objective was to develop nanohydrogel (NG) as a drug-delivery platform for the intra-articular delivery of the two peptides.Methods:Human-derived chondrocytes were treated with BQ123 and/or R954 (25-1000 ?M) to determine cell viability by MTS/LDH assays. The effect on inflammatory protein expression and on catabolic and anabolic markers was assessed by western blotting using specific antibodies of NF?B, COX2, NOS2, COL2A1, SOX9 and MMPs. MMP2 and MMP9 enzymatic activity was also evaluated by zymography. Immunohistochemistry was performed to determine ETA, BKB1, collagen type II and COX2 expression. Cartilage thickness was measured from Safranin-O-stained histology of OA rats knees treated intraarticularly with the ETA/BKB1 antagonists. Additionally, BQ123 and R954 were chemically conjugated to biopolymers to synthesize NG using an ionic gelation process.3Results:Cell viability was not affected by BQ123 or R954. Both activation of the inflammatory proteins NFkB, COX2 and NOS2, and MMPs' catabolic effects were reduced with BQ123/R954 combination after 6 and 24 hours of treatment respectively. In tissue, BQ123/R954 treatment significantly reduced ETA and BKB1 expression, while cartilage thickness was significantly increased in OA rats' knees. NG-BQ123 and NG-R954 were successfully synthesized with a size of ~427 nm and a positive charge of ~41 mV, allowing the rapid internalizing by chondrocytes after 24 hours.Conclusion:We demonstrated that the dual inhibition of ETA and BKB1 reduced both the expression of inflammatory proteins and the activity of cartilage degradation enzymes in vitro, and increased articular cartilage thickness in vivo, thus showing that ETA and BKB1 antagonists could be a promising new treatment for OA. Finally, functionalized peptides NGs for intra-articular treatment were successfully synthesized.

Non-oxidizable fully reduced HMGB1 improves osseointegration in diabetic conditions *Claudia Biguetti[1], Bhuvana Lakkasetter Chandrashekar[2], Peter Elvin[1], Alexandra Arteaga[2], Danieli Rodrigues[2]. [1]University of Texas Rio Grande Valley, United States. [2]University of Texas at Dallas, United States

Diabetes is a metabolic disorder characterized by chronic hyperglycemia and dysregulated inflammatory response, which impairs bone healing and osseointegration of dental implants. The high mobility group box-1 (HMGB1) protein, particularly a non-oxidizable fully reduced isoform of this protein (FR-HMGB1), has been found to enhance SCs proliferation and accelerate bone healing at the injury sites. The present study aimed to assess the potential of FR-HMGB1 to improve osseointegration in both in vitro and in vivo diabetic models. Murine pre-osteoblasts (MC3T3-E1 cells) were treated with 1µg/mL of FR-HMGB1 in a complete culture medium under normal glucose (5.5?mM) or high glucose (30mM) levels. For the in vivo osseointegration model, a titanium screw was inserted in the first upper molar palatine root socket of 12-week-old 129Sv mice. Diabetic (D) mice were produced by administering a high-fat diet for six weeks and two IP injections of streptozotocin (100mg/Kg) one week before implant placement. Control non-diabetic (ND) and D groups were treated with a local injection of 20µL of PBS, while ND- and D-HMGB1 groups were treated with 20µL of FR-HMGB1 (7.5mg/Kg). Five implanted bone samples from each group were harvested at 7 and 21 days post-surgery for histological and microcomputed tomography (MicroCT) analysis (bone to implant contact, BIC %). Our in vitro results demonstrated that the viability of MC3T3-E1 cells was significantly reduced under high glucose levels compared to controls. FR-HMGB1 treatment significantly increased osteoblasts proliferation in normal glucose levels and rescued cell proliferation capacity in diabetic conditions. Clinically, D-Control mice showed inflammation and incomplete epithelization at day 7, while other groups had implants entirely covered by oral mucosa. Histological results demonstrated persistent chronic inflammation in D controls, while D treated with FR-HMGB1 exhibited increased numbers of Runx-2 positive osteoblasts and successful bone formation surrounding implants, comparable to ND control and ND-FR-HMGB1 groups. MicroCT revealed that 80% of both ND control groups and 60% of D mice treated with FR-HMGB1 were successfully osseointegrated (> 60 % BIC %), whereas the average BIC % was significantly reduced in D-Controls. In conclusion, non-oxidizable FR-HMGB1 improved osseointegration in diabetic models, suggesting its potential to be a therapeutic target for implant procedures in diabetic patients.

Nanogels for the drug delivery of antagonist peptides of ETA and BKB1 receptors for OA treatment *Seng Manivong[1], Araceli Garcia Ac[2], Line Séguy[1], Pierre Sirois[3], Xavier Banquy[2], V. Gaëlle Roullin[2], Florina Moldovan[4]. [1]CHU Sainte-Justine, Research Center; Université de Montréal, Faculty of Pharmacy, Canada. [2]Université de Montréal, Faculty of Pharmacy, Canada. [3]Université Laval, Faculty of Medicine , Canada. [4]CHU Sainte-Justine, Research Center; Université de Montréal, Faculty of Dentistry, Canada

IntroductionOsteoarthritis (OA) affects millions of people worldwide with daily physical disability and pain (Glyn-Jones et al., 2015). There is unfortunately no pharmacological cure to date, partly due to the complex and avascular structure of the cartilage representing a major obstacle for drug delivery within the joint (Brown, Kumar and Sharma, 2019). Our laboratory has previously shown that the synergistic inhibition of endothelin-1 (ETA) and bradykinin (BKB1) receptors by two peptides, namely BQ123 and R954 respectively, can decrease pain and also prevent cartilage degradation in an OA rat model (Kaufman et al., 2011). Hence, our goal was to develop a drug delivery system (DDS) for this promising therapy enabling its local and long-term delivery in the cartilage. Biopolymeric nanogels (NG) were selected due to their mimicking extracellular matrix with high-water content, together with their high-loading capacity, and drug-controlled, sustained release to target tissues (Manivong et al., 2023).MethodsFunctionalized chitosan (CH-BQ123 and CH-rhodamine B) / hyaluronic acid (HA-R954) nanogels (NG) were synthesized using an ionic gelation process (Callewaert et al., 2014), resulting in CH-BQ123 NG, HA-R954 NG and fluorescent NG-rhodamine B. Particle sizes (Dh), polydispersity indexes (PdI), and zeta potentials (ZP) were characterized by dynamic and electrophoretic light scattering respectively (DLS and ELS). NG toxicity was determined by MTS/LDH and TUNEL experiments up to 5 days of treatment on human chondrocytes and NG-rhodamine B cell internalization by fluorescence microscopy. Finally, NG efficacy, compared to the free peptides, will be assessed in vitro regarding protein expression of anabolic and catabolic markers, with and without pre-enzymatic digestion of the NG.Results and conclusionCH-BQ123 and HA-R954 NG were obtained with sizes of ~427+/- 58 nm and a positive charge of ~41+/- 6 mV, which will allow the local and persistent deposition of the peptide NG in the negatively charged cartilage. Indeed, NG were rapidly internalized in vitro by chondrocytes without showing any cytotoxicity up to 5 days of treatment. In addition, non-digested NG appears to be able to decrease the catabolic proteins MMP1 and MMP2 expression and to increase aggrecan, the major proteoglycan in articular cartilage, under inflammatory conditions. Overall, CH-BQ123 NG and HA-R954 NG were successfully synthesized and show capacity to deliver peptides to the joint.

Role of Hypoxia-inducible factor-1? (HIF-1?) in Intramembranous Bone Regeneration *Hoomin Lee[1], Yun Suk Huh[2], Frank Ko[3]. [1]Rush University Medical Center, United States. [2]Inha University, Republic of Korea. [3]Rush University, United States

Intramembranous bone regeneration plays an important role in orthopaedic and dental procedures. Despite the increasing importance of intramembranous bone regeneration, the underlying mechanisms of intramembranous bone regeneration remain unclear. HIF-1? plays a pivotal role in many pathways such as angiogenesis, cell migration and cell differentiation, and is well known to promote bone formation and endochondral bone regeneration through these roles. However, studies to date have yet examine the role of HIF-1? activation or inhibition on intramembranous bone regeneration. We therefore sought to determined the effects of the HIF-1? activation or inhibition on mice that underwent surgical ablation of bone marrow, a well-established intramembranous bone regeneration model. At 4 weeks of age, mice underwent surgery and were administered every 2 days with 30 µg/g of 2-methoxyestradiol (2ME2) or 10 µg/g of dimethyloxaloylglycine (DMOG) to inhibit or activate HIF-1?, respectively. We performed a microcomputed tomography analysis of post-surgery day 7 regenerating bone marrow BV/TV and found that the activation of HIF-1? was not different compared to the control, whereas HIF-1? inhibition by DMOG impaired intramembranous bone regeneration by 25%. These data suggest that HIF-1? is necessary for intramembranous bone regeneration and may improve efficiency of fracture healing or enhance implant fixation.

Bioswitchable Delivery of microRNA by DNA origami: Application in Bone Regeneration *songhang li[1], Taoran Tian[2], Yunfeng Lin[2], xiaoxiao cai[1]. [1]State Key Laboratory of Oral Diseases National Clinical Research Center for Oral Diseases, West China Hospital of Stomatology, Sichuan University, China. [2]Sichuan University, China

Background: In recent years, microRNA (miR) therapy has become the main focus of miR research. However, its inherent instability greatly limits its therapeutic applications. In the field of drug delivery, tetrahedral framework nucleic acid (tFNA) constructed using DNA origami as a stable drug delivery system is attracting considerable attention in DNA nanomaterial research because of its good biocompatibility and high cell membrane permeability. Therefore, loading miR on tFNA and transporting them into cells may overcome the limitations of miR instability, thereby expanding the applicability of miRs. However, the loaded miRNA has poor structural stability because it is single-stranded. After entering the cell, the presence of the vector tFNA may affect the efficiency of miRNA due to the lack of detachment mechanism.Aim: This study aims to build a bioswitchable miRNA delivery system based on tFNA with high stability by optimizing the delivery system. And in this study, an RNase H-responsive sequence is applied to connect a sticky-end tFNA (stFNA) and miR-2861, which is a model miR, to target the expression of histone deacetylase 5 (HDAC5) in BMSCs. The resultant bioswitchable nanocomposite (stFNA-miR) enables efficient miR-2861 unloading and deployment after intracellular delivery, thereby inhibiting the expression of HDAC5 and promoting osteogenic differentiation.Methods: Using four specific ssDNA to form stFNA, and assemble it with miR2861 to construct stFNA-miRNA2861; MiR-qPCR were used to verify the opening of the bioswitch. The expression of target protein HDAC5 and osteogenesis-related proteins were observed by western blot and laser confocal microscope; the osteogenic differentiation of BMSCs induced by stFNA-miR2861 was observed by alkaline phosphatase staining and alizarin red staining. Micro-CT was used to analyze the internal structure of bone defects; H&E staining and Masson staining were used to observe the results of repair and collagen formation.Conclusion: Herein, we have confirmed that this delivery system can be successfully assembled. This study verified the effectiveness of the RNase H-activated switch structure in the carrier. In vitro and in vivo experiments verified that the structure of stFNA-miR2861 can promote bone regeneration. In addition, owing to the excellent editability within tFNA, this delivery system can be used as a platform for the delivery of other nucleic acid drugs and nucleic acid-like drugs in the future.

Role of Discoidin Domain Receptor 2 in Tooth Socket Healing *RENNY FRANCESCHI[1] Rajay Kamath[1] [1]University of Michigan, United States

Discoidin Domain Receptor 2 (DDR2) is a collagen-activated tyrosine kinase required for skeletal development and regeneration of the calvaria and long bones, however, possible functions in alveloar bone have not been examined. The present study used lineage tracing, as well as global and conditional knockout approaches, to examine functions of Ddr2 in alveolar bone regeneration during tooth socket healing. The following mouse lines were used: DDR2LacZ (where the bacterial LacZ gene is inserted into the Ddr2 locus creating an effective null allele), Ddr2CreERT2; Rosa26GtTdtomato and Gli1CreERT2 Rosa26GtTdtomato for lineage tracing, and the Gli1CreERT2; DDR2fl/fl mice for the selective knockout of Ddr2 in GLI1+ skeletal progenitors. For lineage tracing, 4w old Ddr2CreERT2; Rosa26GtTdtomato and Gli1CreERT2 Rosa26GtTdtomato mice were induced with one dose of tamoxifen and the 1st molars were extracted after 2 or 7 days. In both cases, TdTomato+ cells migrated into the sockets where they co-localized with OSX, a preosteoblast marker. Thus, both DDR2 and GLI1+ cells contribute to socket healing. The considerable overlap observed between DDR2+ and GLI1+ cells suggested that DDR2 largely functioned in GLI1+ cells, which are known to have skeletal progenitor properties. Consistent with localization data, both global Ddr2 (Ddr2LacZ/LacZ) or conditional knockout (Gli1CreERT2; Ddr2fl/fl) mice exhibited reductions in socket healing 1-week post extraction as measured by µCT, but not after 2 or 4 weeks. However, analysis of collagen fibril orientation by picrosirius red staining revealed that collagen fibril orientation was disrupted in tooth sockets at all times examined, suggesting that even though loss of DDR2 only had a transient effect on socket bone fill, it has long-term effects on ECM structure and, potentially, mechanical properties. In summary, this work demonstrates a role for DDR2 in alveolar bone regeneration, a finding that may have therapeutic implications for the treatment of alveolar bone loss asscciated with periodontal disease and other disorders.

Bone-targeted delivery of BMP-2 to promote healing of musculoskeletal injury in a mouse model *Oskar Sundberg[1] Shannon Wu[2] Brendan Shi[2] Varun Sriram[2] Won Kim[3] Dmitriy Sheyn[4] Karen Lyons[2] Weiguang Wang[2] Eldon Hard[1] Matthew Pratt[1] Boris Kashemirov[1] Ichiro Nishimura[5] Thomas Kremen[2] Charles McKenna[1] [1]University of Southern California, United States [2]David Geffen School of Medicine at UCLA, United States [3]University of Ulsan College of Medicine, Republic of Korea [4]Cedars-Sinai Medical Center, United States [5]UCLA School of Dentistry, United States

Musculoskeletal injuries, including rotator cuff tendon tears (RCT), affect millions of individuals annually. Despite surgical treatment, a significant number of RCT repairs fail to heal properly, resulting in suboptimal tissue regeneration. The use of growth factors like bone morphogenic proteins (BMPs) has shown promise in enhancing tendon-bone healing. However, effective delivery strategies remain a challenge. This study describes the design, synthesis and evaluation in a murine model of a bisphosphonate (BP)-based delivery platform for localized targeting and release of a therapeutic BMP cargo.Feasibility was assessed using a previously reported bone imaging-probe (OFS-3) comprised of a bisphosphonate conjugated to a fluorescent dye, linked to an internal quencher via a peptide substrate of Cathepsin K (Ctsk). Male mice underwent Achilles tendon-to-bone repair or sham surgery, followed by local or systemic administration of OFS-3. Imaging was performed at regular intervals up to three weeks post-surgery. Both local and systemic administration of OFS-3 resulted in a localized fluorescent signal at the surgical site, peaking around postoperative day (POD) 7-10. Control groups showed no specific fluorescence, suggesting selective activation at sites where osteoclast Ctsk-activity is associated with bone resorption. Immunohistochemistry staining confirmed the presence of Ctsk-positive cells at early (POD 7) and late (POD 28) time points. Biomechanical testing of repaired hindlimbs receiving OFS-3 injections showed no differences compared to control repaired hindlimbs, indicating that the modified bisphosphonate did not interfere with osteoclast activity and that the delivery platform retained its targeted release function without hindering the healing process.A BP conjugate of BMP2 (BP-BMP2) was then constructed incorporating into the BP-drug linker, the same Ctsk-sensitive peptide sequence used in OFS-3. Evaluation in ATDC5 cells revealed that wt BMP2 and Ctsk-digested BP-BMP2, but not undigested BP-BMP2, stimulate BMP responsive element (BRE) expression in the cells. The results underline the promise of BP-BMP2 as a new approach to improving tendon-bone healing, specifically in the context of RCT repairs.

Injectable Phase-Separated Tetra-Armed Polyethylene Glycol Hydrogel Scaffold Allows Sustained Release of Signaling Factors to Enhance the Repair of Cranial Bone Defects *Shant Nepal[1] Jinyan Si[1] Shohei Ishikawa[1] Hiroyuki Okada[1] Shinsuke Ohba[2] Ungil Chung[1] Takamasa Sakai[1] Hironori Hojo[1] [1]The University of Tokyo, Japan [2]Osaka University, Japan

As the global aging population continues to rise, so are the occurrences of bone injuries, including fractures and defects. While most fractures can naturally heal, nonunion fractures and irreversible bone loss require regenerative strategies. One strategy involves the use of biocompatible synthetic hydrogels as scaffolds and drug delivery systems. Previously, we reported the oligo-tetra-armed polyethylene glycol (PEG) hydrogel (oligo gel) to have low swelling, fast and efficient gelation at low polymer content (Hayashi et al., Nat.Biomed. Eng, 2017). We also reported that at low polymer content, tetra-armed PEG gels undergo gel-gel phase separation (GGPS) and provide bio-affinity (Ishikawa et al., arXiv:cond-mat. soft, 2022). Here, we investigated the oligo gel as a scaffold capable of loading and sustained release of signaling factors to enhance bone regeneration using in vitro and in vivo models. First, we assessed GGPS between low content oligo and conventional tetra-PEG gels (tetra gel). As turbidity was reported to be directly correlated with GGPS, we tested and found the oligo gel was significantly more turbid than the tetra gel. Furthermore, when immersed in a solution of hydrophobic microparticles, we observed a significantly higher number of particles adsorbed on the oligo gel than on the tetra gel. We concluded that the greater degree of GGPS occurring in the oligo gel resulted in more hydrophobic regions within its network. Since this may be advantageous when loading signaling factors or proteins, we then characterized the release profiles from the oligo gel and tetra gel using fluorescein-labeled BSA and rhBMP-2. The oligo gel could release both proteins at a slower, sustained rate compared to the tetra gel. This was further confirmed when applied to MC3T3-E1 osteoblast progenitors in vitro. Next, we applied the oligo and tetra gels loaded with rhBMP-2 to a mouse calvarial defect model. After 28 days, micro-CT of treated mice revealed the oligo gel had significantly enhanced bone regeneration, fully covering the defect with new bone, compared to the tetra gel. Immunohistochemistry further revealed the oligo gel-treated new bone had more expression of RUNX2, a master regulator of osteoblasts, suggesting the presence of more osteoblast progenitors compared to the tetra gel-treated new bone. To conclude, we demonstrated that the greater degree of GGPS allowed the oligo gel to sustain rhBMP-2 release and enhance the repair of cranial bone defects.

Changes in skeletal muscle atrophy over time in a rat model of adenine-induced chronic kidney disease *Kento Okamoto[1] Yuji Kasukawa[1] Koji Nozaka[2] Hiroyuki Tsuchie[3] Daisuke Kudo[2] Hayato Kinoshita[2] yuichi Ono[2] Keita Oya[1] SHUN IGARASHI[4] Shuntaro Harata[4] Naohisa Miyakoshi[1] [1]Akita University Graduate School of Medicine, Japan [2]Department of Orthopedic Surgery, Akita University Graduate School of Medicine, Japan [3]Akita university graduate school of medecine, Japan [4], Japan

Purpose:Chronic kidney disease (CKD) causes muscle atrophy through several mechanisms, including the accumulation of uremic substances, insulin resistance, and mitochondrial dysfunction due to impaired renal function. Similarly, muscle atrophy occurs in CKD model rats, but the changes over time are unknown. In the present study, we investigated the changes over time in muscle atrophy, factors related to muscle differentiation and atrophy, and mitochondrial activity in an adenine-induced CKD rat model.Methods:Eight-week-old male Wistar rats were divided into a control group (n=7) with a normal diet for 4 weeks and a CKD group (n=7) with a diet containing 0.75% adenine for 4 weeks. The paraspinal and tibialis anterior muscles were harvested at 12 and 20 weeks of age. Paraspinal muscles were stained for ATPase and the mean cross-sectional areas of type 1 and type 2 muscle fibers were measured. Succinate dehydrogenase (SDH) staining density was measured and mitochondrial activity was assessed. RNA was extracted from the right tibialis anterior muscle, and the expression of PGC-1?, muscle regulatory factors (MyoD, myogenin), and atrogenes (atrogin-1, MuRF-1) were measured by real-time PCR.Results:Type 1 and type 2 muscle cross-sectional areas were significantly decreased in the 12-week CKD group versus the control group ($p<0.05$), while only type 2 muscle cross-sectional area was significantly decreased in the 20-week CKD group ($p<0.05$). SDH staining levels, which reflect mitochondrial activity, were also significantly lower in the 12-week CKD group vs. the control group ($p<0.05$), but there was no significant difference between the two groups at 20 weeks of age. The expression levels of atrogenes (Atrogin-1, MuRF-1) and myogenin were significantly increased ($p<0.05$) and MyoD was decreased ($p<0.05$) in the 12-week CKD group vs. the control group, but there were no significant differences in the expression of muscle regulatory factors or atrogenes at 20 weeks.Conclusion:In the adenine-induced CKD rat model, type 1 and type 2 muscle cross-sectional areas were decreased early after adenine administration, but type 1 muscle cross-sectional area recovered over time. This phenomenon is believed to involve a decrease in mitochondrial activity and an increase in atrogenes.

Schwann cells and skeletal stem/progenitor cells in periosteum drive fibrosis and congenital pseudarthrosis of the tibia in NF1 *Simon Perrin[1] Sanela Protic[1] Ingrid Laurendeau[2] Oriane Duchamp de Lageneste[1] Nicolas Panara[2] Cécile-Aurore Wotawa[1] Odile Ruckebusch[3] Marine Luka[4] Cécile Masson[5] Théodora Maillard[6] Stéphanie Pannier[7] Philippe Wicart[7] Smail Hadj-Rabia[8] Katarzyna Radomska[1] Mickael Ménager[4] Dominique Vidaud[6] Piotr Topilko[1] Béatrice Parfait[2] Céline Colnot[1] [1]Univ Paris Est Creteil, INSERM, IMRB, Creteil, France, France [2]INSERM UMR S1016, Institut Cochin, Université de Paris, Paris, France, France [3]Univ Paris Est Creteil, INSERM, IMRB, Plateforme de Cytométrie en flux, Creteil, France., France [4]Paris Cité University, Imagine Institute, Laboratory of Inflammatory Responses and Transcriptomic Networks in Diseases, Atip-Avenir Team, INSERM UMR 1163, Paris, France., France [5]Bioinformatics Core Facility, Institut Imagine-Structure Fe?de?rative de Recherche Necker, INSERM U1163 , France [6]Service de Médecine Génomique des Maladies de Système et d'Organe, Hôpital Cochin, DMU BioPhyGen, Assistance Publique-Hôpitaux de Paris, AP-HP, Centre-Université Paris Cité, F-75014 Paris, France, France [7]Department of Pediatric Orthopedic Surgery and Traumatology, Necker-Enfants Malades Hospital, AP-HP, Paris Cité University, Paris, France, France [8]Department of Dermatology, Reference Center for Rare Skin Diseases (MAGEC), Imagine Institute, Necker-Enfants Malades Hospital, AP-HP, Paris Cité University, Paris, France. , France

The periosteum, the outer layer of bones, is a crucial source of skeletal stem/progenitor cells (SSPCs) for bone healing. The role of periosteum in bone repair disorders is poorly understood but suspected in congenital pseudarthrosis of the tibia (CPT). CPT is a severe pathology marked by tibial bowing leading to spontaneous fractures and fibrous non-union. Half of CPT cases are linked to Neurofibromatosis type 1 (NF1), a genetic disorder caused by mutations in the NF1 gene, encoding the RAS negative regulator neurofibromin. NF1 is characterized by a wide range of symptoms, such as tumors (neurofibromas, NFBs), skin hyperpigmentation and skeletal manifestations, including CPT. While NF1 neurodermatological manifestations are known to arise from NF1 biallelic inactivation in Schwann cells and melanocytes, the cellular origin of CPT remains unknown. Recently, analysis of the Prss56-Nf1 KO mice, revealed that boundary-cap cells, a transient population of neural-crest derivatives, is the population responsible for both neurofibromas and skin hyperpigmentation (Radomska et al.). These results raised the question of a possible common cellular origin of NF1 neurodermatological and skeletal symptoms.In this study, we unraveled the cellular origin and pathogenic mechanisms of CPT through analyses of bone samples from 17 CPT patients and Prss56-Nf1 KO mice. We showed that CPT is associated with NF1 biallelic inactivation in human periosteum. SSPCs in pathological periosteum exhibit NF1 biallelic inactivation and a pro-fibrotic phenotype. We identified an increased proportion of pERK+ Schwann cells (SCs) in pathological periosteum. Overall, analyses of CPT patients revealed SSPCs and SCs as affected cell types in CPT. In parallel, we described the pseudarthrosis phenotype of Prss56-Nf1 KO mice, due to Nf1 loss in boundary cap-derived SSPCs and SCs in periosteum. Single nuclei analyses of the periosteum showed that Nf1 KO SSPCs fail to undergo chondrogenic differentiation leading to fibrogenic differentiation. More strikingly, we identify Nf1 KO SCs as the main driver of fibrotic accumulation in CPT as they acquire a pro-fibrotic function and promote fibrotic fate of wild-type SSPCs via TGF?. We demonstrate that TGF? inhibition prevents pseudarthrosis in Prss56-Nf1 KO mice. These results establish the pro-fibrotic role of boundary cap-derived SCs and SSPCs causing CPT in NF1. This study suggests new therapeutic strategies targeting SC-derived pro-fibrotic factors, including TGF?, for CPT.

Impaired Fracture Healing in Mice with Targeted Disruption of the Claudin-11 Gene *Charles Rundle[1] Sheila Pourteymoor[1] Subburaman Mohan[1] [1]Jerry L. Pettis Memorial VA Medical Center, United States

The claudin multigene family encodes tetraspan membrane proteins that provide structural and functional components of tight junctions and play important roles in regulating paracellular permeability. However, recent investigations also support a role for the claudins in non-canonical intracellular signaling in bone and in other tissues. In previous studies, we demonstrated that targeted disruption of the Claudin-11 gene in mice significantly reduced the trabecular bone mass by influencing osteoblast-mediated bone formation.To determine whether Claudin-11 functions also mediate bone repair, we examined fracture healing during the endochondral bone formation phase of healing in Claudin-11 knockout and their corresponding wild-type control littermate mice. A standard closed femur fracture was produced in Claudin-11 knockout (n=7) and control (n=7) mice and fracture tissues were examined following four weeks of healing. Both male and female mice were used.Analysis of the fracture callus at four weeks of healing by microCT revealed no significant differences in fracture callus volume between Claudin-11 knockout and control mice. Histology analyses of fracture callus area in trichrome-stained sections, however, revealed that there was a reduced area of woven bone detected when normalized to callus area in Claudin-11 knockout mice compared to control mice (0.19 +/- 0.03 in knockouts vs 0.28 +/- 0.19 in controls, $P < 0.05$). Furthermore, there was a reduction in the number of osteoclasts detected by TRAP

staining in the total callus woven bone (113 +/- 33 in knockouts vs 176 +/- 69 in controls, $P < 0.05$). These observations are consistent with Claudin-11 regulation of both osteoblast and osteoclast development in callus bone formation at this stage of fracture repair. Further time course studies will address the mechanisms for impaired fracture healing in Claudin-11 knockout mice.

Novel Role of lncRNA H19 in Osteoarthritis Subchondral Bone Remodeling and Treatment *Rongliang WANG[3], Babak Mehrjou[2], Dorsa Dehghan-Baniani[3], Michael Tim yun Ong[3], Hon Fai Chan[3], Gang Li[3], Paul K Chu[4], Wayne Yuk Wai Lee[5]. [3]The Chinese University of Hong Kong, China. [2] City University of Hong Kong, Hong Kong. [3]The Chinese University of Hong Kong, Hong Kong. [4]City University of Hong Kong, Hong Kong. [5]The Chinese University of Hong Kong; CUHK InnoHK Centres, Hong Kong

INTRODUCTION: Emerging evidence suggests that aberrant subchondral bone remodeling upon excessive mechanical loading might play important role in early onset of osteoarthritis (OA). A long non-coding RNA (lncRNA) H19 was reported to be associated with OA progression and regulate mechano-transduction at cellular level, however, its role in OA subchondral bone has not been reported. This study aimed to examine the relationship between H19 and OA subchondral bone remodeling, and to develop a novel strategy for OA treatment via targeting H19. METHODS: Subchondral bone were collected from patients with knee OA undergoing joint replacement surgery. Wild-type C57BL/6 mice and same genetic background transgenic mice with osteocyte-specific deletion of H19 (cKO) mice were used, and OA phenotype was induced by destabilization of the medial meniscus (DMM) surgery. To verify the effect of mechanical stimulation on osteocytes, MLO-Y4 cells were subjected to unidirectional fluid shear stress (FSS) followed by RNA sequencing analysis. We developed a specific gene-delivery system by combining Fe3O4 nanoparticles and metal-organic frameworks (MOFs) to form a magnetic MOFs (MMOFs) for the delivery of anti-H19 antisense oligonucleotides (ASOs) to the target site in the presence of external magnetic field. RESULTS: Human subchondral bones of end-stage OA had higher expression level of H19, which was associated with increased bone mass and more H19 expressing osteocytes. In wild-type mice, DMM surgery led to cartilage damage, subchondral sclerosis, and increased H19 expression in subchondral bone. On the contrary, cKO mice with H19 ablation were much less vulnerable to DMM induced OA phenotypic changes. In MLO-Y4 cells, H19 induced PI3K/AKT/GSK signaling activation and mediated osteocytic mechano-response upon FSS stimulation. Finally, MMOFs were successfully synthesized, and shown as an efficient delivery system with satisfactory distribution to the target site and effectiveness in terms of down-regulating H19 expression, which remarkably alleviated subchondral bone remodeling and OA phenotype. DISCUSSION: Our results provide new evidence that elevated H19 expression in osteocytes could contribute to the aberrant subchondral bone remodeling and subsequently cartilage damage in OA development. H19 appears to be required for osteocytic response to mechanical stimulation, and targeting H19 represents a promising new approach for OA treatment.

Explore the roles of PIEZO1 and YAP in promoting osteogenesis and angiogenesis of 3D-printed vascularized bone organoids under mechanical stimulations *Jia-Fwu Shyu[1], Tzu-Hui Chu[1], Yu-Chih Lo[1], Yi-Ting Lai[1], Yu-Min Tsai[1], Yu-Cheng Kang[1], En-Han Huang[1]. [1]National Defense Medical Center, Taiwan, Province of China

Mechanobiology is an emerging field investigating the translation of physical forces into molecular biological signals. These forces can greatly impact cell behavior, countering or synergizing with other cellular signals from soluble factors. Mechanical forces can stimulate cellular mechanosensors, such as the ion channel PIEZO1 and transcriptional co-activator YAP. These proteins regulate the metabolism of bone cells and remodeling. However, the regulation of PIEZO1 and YAP activity under mechanical stimulation in bone tissue is still unknown. In this proposal, we used compressive and fluidic stimulations to investigate the response of PIEZO1 and YAP in osteoblasts and endothelial cells. Using a 3D bioprinter, polycaprolactone was extruded to simulate the endosteum and trabecular bone. Seeding of osteoprogenitors on PCL was performed to fabricate bone orgaonid. GelMA hydrogels mixed with HUVECs were printed into a hollow tubule vessel structure. The vascularized bone organoid (VBO) was fabricated by insertion of artificial vessel into bone organoid. In the VBO dynamic culture under compression, results from Cell counting kit-8 assay showed viability and proliferation of both osteoblasts and HUVECs for over 28 days. Increased mineralization and bone formation in VBO were observed by Alizarin Red staining and Micro-CT analysis. Western blotting and RT-PCR showed increase expression of PIEZO1 and YAP. Increase immunofluorescence staining for CD31 by confocal microscopy indicated blood vessel formation. In addition, activators (Yoda1) and inhibitors (GsMTx4) of PIEZO1 were used for pharmacological studies of PIEZO1 signaling. It is hoped that these results may provide in-depth insight into mechanotransduction in bone tissue and new methods for treating bone diseases such as osteoporosis and bone fractures.

Neoangiogenesis at chondro-osseous Interfaces in Bone growth and Fracture healing is impaired in absence of Syndecan-1 *Richard Stange[1], Christian Arras[2], Nils Roters[3], Daniel Kronenberg[3], M. Gabriele Bixel[4], Ralf H. Adams[4], Melanie Timmen[3]. [1]University Hospital Muenster, Germany. [2]University Hospital Hamburg, Germany. [3]Institute of Musculoskeletal Medicine (IMM), University Hospital Munster, Germany. [4]Max-Planck-Institute for Molecular Biomedicine , Germany

Background: Neoangiogenesis drives the replacement of mineralized cartilage by trabecular bone during bone growth regulated by molecules like e.g. VEGF, OPG and RANKL. The Heparan sulfate proteoglycan Syndecan-1 (Sdc1) while interacting with VEGF and OPG, plays a role in the communication of osteoclasts and osteoblasts and in the development of blood vessels. To understand the function of Sdc1 in enchondral ossification we analysed bone structure and vessel development in bone growth and fracture healing in mice deficient in Sdc1.Methods: Femora of C57BL/6 WT (n=11) and Sdc1-/- (n=13) mice (male/female) were used for native bone analysis at 4 month age. Female mice (WT n=6-14, Sdc1-/- n=6-8, per time point) underwent midshaft femur fracture stabilized using an intramedullary nail and healed for up to 28 days. Bone structure was analysed using microCT scans with a resolution of 9µm. Fracture callus composition was quantified after Alcian Blue staining as callus area, fibrous tissue, cartilage and trabecular bone in 5µm thick slices. Vascularisation was visualised using an anti-Endomucin antibody in 80µm thick cryosections. Bone marrow isolates (WT/Sdc1-/-) were used to generate endothelial progenitor cells by sequential cultivation on fibronectin. Microvessel development was analysed 4h after plating on matrigel.Results: Bone structure in 4 month old male Sdc1 deficient mice was significantly reduced compare to age matched male WT, whereas female mice of both genotypes did not differ. Sdc1 deficient mice showed a significant less number of vessel buds at the chondro-osseous border at the growth plate at the age of 4 month compared to WT mice in male and female mice. During fracture healing, callus development was delayed with regard to cartilage area at day 7 and trabecular bone area at day 14. A decreased number of vessel buds invading at the borderline of cartilage to bone in the callus were counted in Sdc1 deficient callus tissue. Quantification of microvessel outgrowth of endothelial cells from bone marrow in matrigel revealed a decreased amount of sprouting, but increased length of microvessels of Sdc1-/- cells compared to WT.Conclusion: Syndecan-1 has a significant impact on neoangiogenesis at the chondro-osseous border of the native bone as well as during bone healing in the callus area. This emphasises the importance to further characterise the mechanism, how Syndecan-1 regulates the process of endothelial invasion during enchondral ossification.

Scaffold-based Approach to Regenerating the Cranial Suture Stem Cell Niche through Pore Design *BEN SWANSON[3], Lindsey Douglas[4], Seth Woodbury[4], Maiko Omi[3], Hwa Kyung Nam[4], Peter Ma[4], Nan Hatch[4], YUJI MISHINA[4, 3], . [4]University of Michigan, United States. [3], United States. [4]University of Michigan,

Craniosynostosis is a debilitating disease characterized by premature fusion of cranial bones, caused by depletion of the suture mesenchyme. Previously we reported that scaffold pore size controls differentiation and loss of stemness through YAP/TAZ modulation. Here, we developed a multicompartment scaffold that recapitulates the suture stem cell (SC) niche within engineered bone. We aimed to test the hypothesis that a triphasic scaffold with distinct regions of sufficiently small (S, SC-maintaining) pores sandwiched by large pores (L, favors differentiation), can maintain an SC niche in the bone microenvironment.Nanofibrous, macroporous scaffolds are fabricated from poly (L-lactic acid) by a sugar-sphere method. In a subcutaneous implantation model, CD31 IHC demonstrates the triphasic scaffold's ability to control vascularization, and picrosirus red analysis demonstrates control of ECM composition, regionally. These phenotype differences are more dramatic in center-seeded scaffolds compared to uniformly seeded. In vitro gene expression of primary BMSCs for SC markers indicates that center-seeded triphasic scaffolds have more remarkable maintenance of stemness in the S region versus uniform seeding, suggesting migration from the center to L-pores. We then co-seeded fluorescently labeled naïve and BMP-treated MSCs to either

the center or uniformly and monitored their migration over time to determine that differentiating, but not naïve, MSCs selectively migrate from the S-pores to the L-pores as soon as 48 hours, maintained up to 2 weeks. To further probe this phenomenon and the fate of SCs in the triphasic scaffold, we transplanted primary BMSCs isolated from tamoxifen-induced HoxA11Cre;TdTomato;Col1eGFP mice, seeded to the center region of triphasic scaffolds or monophasic large pore scaffolds, to a parietal bone defect and sacrificed at 2, 4, and 8 weeks. uCT demonstrates the triphasic scaffold's ability to resist bone formation in the center region compared to a large pore scaffold. Confocal microscopy traces the fate of red HoxA11+ SCs and their evolution of Col1eGFP signal. The exact mechanism of migration is still under investigation. Our evidence suggests that a triphasic tissue engineering scaffold can maintain a skeletal SC niche by differential modulation of cell fate. A tissue engineering approach is promising to reestablish the suture SC population to improve the efficacy of surgical craniectomies and re-establish skull growth.

Rapid Bone Regeneration via Mesenchymal Stem Cell Recruiting by Framework DNA Nanodevice *Taoran Tian[1], Xingyu Chen[1], Songhang Li[1], Yunfeng Lin[1]. [1]Sichuan University, China

On-site recruiting of endogenous stem cells is promising for eliminating insufficient sources and ethical/regulatory considerations. However, the scant of cell-recruiting devices with high specificity hampers the development of this strategy. Tetrahedral framework DNA nanostructure (tFNA) has been verified to be a potent tool for biomedical purposed-functionalization. To acquire an MSC-targeted binding, we modified the tFNA structure with mesenchymal stem cell (MSC) targeted aptamer Apt19S. The MSC binding tFNA nanodevice was then loaded onto the hyaluronic acid (HA) hydrogel to achieve on-site stem cell recruiting and rapid bone regeneration in craniofacial bone defects. The tFNA was first fabricated via a one-pot approach by annealing four single-strand DNA (ssDNA). Successful fabrication of the tFNA was verified by cryo-EM, DLS, and gel electrophoresis. One to three Apt19S were loaded onto the apexes of the tFNA (denoted as T1, T2, and T3 according to the number of Apt19S attached) to titrate the nanodevice with the best MSC binding affinity. Flow cytometry and laser confocal microscopy indicated that T3 acquired the maximum cell labeling efficiency. Hence, the T3 structure was selected as the MSC capture nanodevice. Further, the remaining apex of tFNA was modified with a thiol group, which could conjugate with the maleimide group on the modified HA strand. The nanodevice-loaded HA hydrogel was then denoted as HA-T3. Rat-derived MSC was cultured and applied to verify the MSC recruiting ability of the HA-T3 hydrogel by a transwell cell culture. With HA-T3 located at the lower chamber of the transwell dish, MSC in the upper chamber migrated and located more onto the siling of the bottom side. Once the MSC recruiting was established in vitro, we set two craniofacial bone defects to verify the efficiency of HA-T3 regarding bone regeneration. Rat skull defect and rat molar tooth extraction socket were created and filled with HA-T3 hydrogel. Animals were sacrificed after 8 weeks of healing. MSC-specialized BRDU staining verified the potent stem cell recruiting in the HA-T3-filled defects, and the enhanced bone regeneration was revealed via micro-CT evaluations. In conclusion, our research established a promising and novel MSC recruiting-facilitated bone regeneration approach. The tFNA-based nanodevice was proven to be a potent tool for the on-site recruiting of endogenous MSC. Further applications could be extended based on our current procedure.

Title: Mesenchymal cell derived VEGFC promotes lymphangiogenesis and aberrant repair following musculoskeletal injury *Neda Vishlaghi[1], Lei Guo[2], Danielle Griswold-Wheeler[3], Yuxiao Sun[4], Janna Crossley[5], Alec Bancroft[6], Sowmya Ramesh[1], Lin Xu[7], Aaron James[7], Robert Tower[7], Michael Dellinger[7], Benjamin Levi[7]. [1]postdoc, United States. [2]COMPUTATIONAL BIOLOGIST I, United States. [3]research tech I, United States. [4]Research scientist, United States. [5]Research Assistant II, United States. [6]Research Tech II, United States. [7]Professor, United States

Heterotopic ossification (HO) is the abnormal growth of bone that forms in non-skeletal tissues following musculoskeletal trauma. While the role of blood revascularization after a musculoskeletal injury has been well characterized, much less is known about the role of lymphatic vasculature in musculoskeletal tissues during homeostasis and after injury. The lymphatic vasculature is essential in transporting fluids, extravasated leukocytes, and antigen-presenting cells in normal and injured tissues. Here, we combine human HO samples with a mouse model of HO-forming tendon injury to determine the functional role of lymphatic vessels in regulating musculoskeletal injury and repair. Prox1eGFP reporter mice showed expansion of lymphatic vessels in human and mouse tissue following injury, driven by elevated levels of active VEGF-C (Vascular endothelial growth factor C) (4.93+/-0.81 vs. 1.76+/-0.13 in uninjured controls, $p<0.001$). Expansion of lymphatic vessels post-injury was also validated by LYVE1 and PDPN immunostaining. Single-cell transcriptomic analyses identified mesenchymal progenitor cells (MPCs) as one of the major sources of Vegfc, and enzymes known to activate Vegfc post-injury. Lineage-tracing of Vegfc-expressing cells with a novel Vegfcwt/CreERT2;R26wt/mTmG system identified a population of MPCs that underwent a significant expansion after injury and directly contributed to the formation of aberrant HO. Our data confirmed that Vegfc lineage cells were also positive for chondrocyte and osteoblast markers 7- and 21-days post-injury. Conditional ablation of Vegfc within MPCs leads to a significant decrease in lymphatic vessel density (17.89+/-4.76 mm2vs. 7.45+/-2.74 mm2in controls, $p<0.001$) and significantly decreases HO formation (2.06 +/- 0.85 mm3 vs. 3.32 +/- 0.66 mm3 in controls, $p<0.05$). Altogether, these data suggest that soft tissue trauma increases VEGF-C expression, particularly within injured tissue MPCs, contributing to this abnormal cell fate decision of MPCs and lymphatic vessel invasion. VEGF-C signaling inhibition at the time of injury may have therapeutic use in soft tissue trauma as a negative regulator of aberrant MPC differentiation and HO.

Scaffold With High Curvature Pores Promotes Segmental Bone Defect Repair by Regulating Skeletal Stem Cells *Liu Yang[1], Lin Minmin[1], Pan Yonghao[1], Liu Hongzhi[1], Chao Liu[1]. [1]Southern University of Science and Technology, China

Mechanotransduction of skeletal stem cells (SSCs) plays a crucial role in mediating angiogenesis-osteogenesis coupling in bone repair. However, approaches to regulate SSCs' mechanotransduction for the repair of large bone defects have been lacking. Our previous study identified that pores with high curvature could enhance the proliferation, migration, and osteogenic differentiation of osteoprogenitor cells. In this study, we aimed to investigate whether mechanobiological optimization of pore curvature in 3D scaffolds could regulate SSCs and improve bone regeneration in vivo. All animal procedures were approved by the Southern University of Science and Technology Animal Care and Use Committee. Experiments were performed on 16-week-old female C57BL6 mice (N=27) and Prx1-Cre; tdTomato mice (N=9). Two types of scaffold designs were used: octet truss and Kelvin cell. Subcutaneous implantation was performed to test biological compatibility. Scaffolds were implanted into 2 mm unilateral femoral segmental defects with external fixation. Defects without scaffold were used as controls. At 2, 4, and 8 weeks after surgery, femurs were imaged by micro-computed tomography (?-CT), SSCs and angiogenesis-osteogenesis coupling markers were measured by immunofluorescence staining, collagen fibers were imaged with second harmonic generation (SHG). We fabricated mechanobiological optimized scaffolds (Figure 1A). Octet truss had higher crack resistance and mechanical strength (Figure 1B). After 2 weeks of subcutaneous implantation, octet truss scaffold had the highest Osterix (OSX) and type H vessel volume. Octet truss also had a higher number of perivascular osteoblasts (OSX+) in proximity to type H vessels at the corner of the scaffold (Figure 1C). After 2 weeks in a segmental defect, octet truss group had more paired-related homeobox protein 1 (Prrx1) +, leptin Receptor (LepR)+, and Gli1+ cells within the defects (Figure 1D). Furthermore, the orientation of collagen fibers was aligned with the scaffold surface. Together, high pore curvature alone such as those in acute angles could increase the number of SSCs and promote segmental bone defect repair.

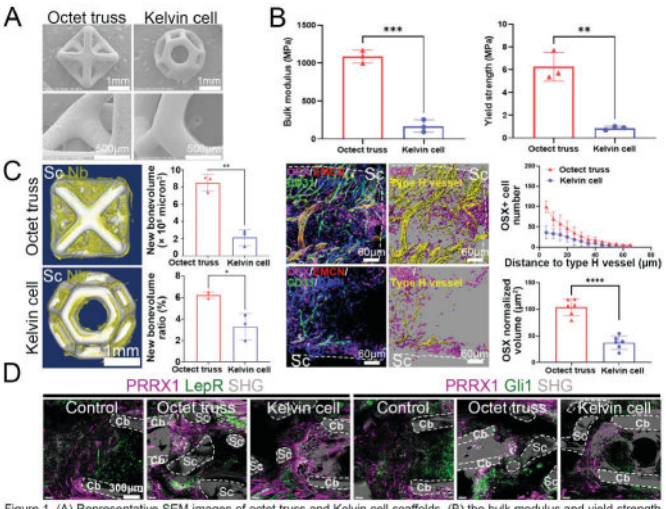

Figure 1. (A) Representative SEM images of octet truss and Kelvin cell scaffolds. (B) the bulk modulus and yield strength of octet truss and Kelvin cell scaffolds. (C) representative images and quantification results of μ-CT 2 weeks after subcutaneous implantation (scale bar = 60 μm), representative maximum intensity projections, 3D surface images and quantification results of OSX, EMCN, CD31 and DAPI immunofluorescence microscopy (scale bar = 60 μm) 2 weeks after subcutaneous implantation. (D) the immunofluorescence images of PRRX1, LepR, Gli1, and SHG in the segmental defects 2 weeks after implantation in femoral segmental defects. n = 3, *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001. Nerve Growth Factor Receptor Limits Inflammation to Promote Remodeling and Repair of Osteoarthritic Joints *Lan Zhao[1], Yumei Lai[1], Jian Huang[1]. [1]Rush University Medical Center, United States

Osteoarthritis (OA) is a painful joint disease affecting more than 500 million people around the world. OA is currently incurable, and management of OA focuses on pain relief. Monoclonal antibodies against nerve growth factor (NGF), which had hold promise as a new class of analgesics to treat OA pain, were discontinued for their clinical development, due to joint safety events like rapid progressive osteoarthritis (RPOA) characterized as accelerated bone destruction in osteoarthritic joints. The mechanisms underlying this observation are elusive, and a possible explanation could be that inhibition of NGF signaling negatively regulates joint remodeling and stabilization during OA. However, it is largely unknown whether NGF signaling has a role in non-neuronal skeletal cells and joint pathophysiology. Here we report that nerve growth factor receptor (NGFR) has significant expressions in skeletal cells including chondrocytes and osteoblasts and plays an essential role in enhancing bony changes to stabilize osteoarthritic joints. Both NGF and NGFR were upregulated in both human and murine joints with OA. We generated NgfrAcan-CreER mice, and surgically induced OA. As skeletal progenitor cells (SPC) express Aggrecan, NGFR deficiency in multi-type joint skeletal cells (also the descendent cells of SPC), was continuously induced through weekly injection of tamoxifen during the course of OA progression. We found that NGFR loss-of-function in SPC and descendent osteochondral cells markedly reduced osteophyte growth by 36% and subchondral sclerosis by 21%, which are thought to be a spontaneous reaction of the diseased joints to repair and stabilize themselves during OA. Moreover, NGFR deficiency downregulated BMP-SMAD1 signaling in cultured skeletal cells and in joint tissues, and enhanced the production of RANKL and thus increased the ratio of RANKL/OPG, which promoted osteoclastogenesis and enhanced bone resorption, in the context of osteoarthritic conditions. Further, we found that NGFR loss-of-function exacerbated NF-?B activation induced by inflammatory cytokines like TNF-?, which may underlie weakened BMP-SMAD1 signaling and upregulated RANKL expression. Importantly, NGFR is also negatively associated with NF-?B activation in human OA cartilage. Together, our data suggested that NGFR plays an essential role in non-neuronal joint cells to restrict NF-?B signaling and thus to promote bony remodeling and stabilization of osteoarthritic joints.

Notch Jagged1 Coating Enhances 3D-Printed Bone Scaffold Vascularization and Callus Formation *Qinqin Xu[1], Solitro Giovanni[1], Shane Barton[1], yufeng dong[2]. [1]LSU Health-Shreveport, United States. [2]Louisana State University,

Rapid angiogenesis and local vascular penetration are essential to deliver cells and growth factors that promote bone callus formation in large bone defect repair surgery. Although multiple cell signaling pathways are involved in regulation of vessel formation, increasing evidence shows that Jagged1 (JAG1)-mediated Notch signaling plays a crucial role in angiogenesis during development. However, it is unknown whether JAG1-mediated Notch activation could be used to enhance vascularization and bone formation during large bone defect repair. Therefore, in this study, 3D-printed biodegradable Polycaprolactone (PCL) scaffolds with similar biomechanical properties to real bone were coated with JAG1 protein or lgG (a control protein) and seeded with angiogenic endothelial stem cells (ESCs). Cell cultures were used to observe the JAG1-induced ESC vessel tube formation. Tetramethylbenzidine (TMB) assay was performed to monitor the controlled release of JAG1 from PCL scaffolds. Finally, a mouse bone defect model was used to test the in vivo repair ability of JAG1 and ESCs loaded scaffolds. Our results demonstrated that ESCs exposed to JAG1 in cultures resulted in a measurable increase of capillary tube formation with thicker tubes and more connections. TMB assay showed the JAG1 protein cross-linked on the surface of PCL scaffold could hold on to and slowly release JAG1 protein over 11 days and possibly even weeks. Histological assessment of transplanted PCL scaffolds showed bone callus formation surrounding the JAG1-coated scaffolds in the bone defect mouse model was significantly increased when compared to lgG- coated scaffolds at 8 weeks after surgery (Figure 1). More importantly, an enhanced expression of angiogenic markers vWF (Brown) and CD31(Green) was observed in the callus adjunct to JAG1-coated scaffolds at 2 weeks after surgery (Figure 1), suggesting that JAG1 induced rapid ESC angiogenic differentiation and local vascularization in these mice. Taken together, our results support the idea that JAG1 protein-coated PCL scaffold could be used as a novel bone substitute for rapid bone defect repair by enhancing ESC angiogenic differentiation/vascularization and subsequent bone callus formation.

The critical role of gender and age in craniofacial bone healing: a microscopic and biochemical study utilizing 129Sv mice *Hagner Andrade[1], Nataira Momesso[2], Gustavo Simionato[2], Mariza Matsumoto[2], Claudia Biguetti[1]. [1]School of Podiatric Medicine, University of Texas Rio Grande Valley, United States. [2]School of Dentistry, São Paulo State University (UNESP), Brazil

Aging may contribute to slower bone healing in craniofacial bones, but there have been insufficient experimental studies that consider this phenomenon in conjunction with biological sex. The objective of this study was to analyze the effect of aging and biological sex on craniofacial bone features in 129Sv mice, as well as their impact on dental socket healing after tooth extraction. A total of 52 129Sv mice were utilized, with 28 being young (3-4 months) and 24 being aged (17-18 months), equally distributed by biological sex. After an upper right incisor extraction, mouse specimens were collected at 7, 14, and 21 days post-surgery for microtomographic (microCT) and comprehensive histological and immunohistochemical analysis. Mandible, skull bones, and maxillae at 21 days were analyzed by microCT, while blood plasma samples were collected to detect key bone turnover markers (P1NP and CTX-1) using enzyme-linked immunosorbent (ELISA) assay. Aged females depicted a significantly decreased fraction of bone mineralized content (BV/TV, %) in alveolar sockets in comparison to young females and aged males at day 7, and aged males at day 14 post tooth extraction. The mandible relative cortical area of aged females was also significantly decreased in comparison with young females. Histological evaluation by hematoxylin and eosin staining and Goldner trichrome revealed that all alveolar sockets healed at 21 days with inflammation resolution and deposition of new bone. In the histomorphometric analysis, B.Ar/T.Ar was significantly lower in aged females in comparison to young females at 14d, and in comparison to aged males at 21 days. Immunohistochemistry for TRAP revealed increased area density for osteoclasts in alveolar sockets of aged females (6.80+/-1.757) when compared to aged males (0.75+/-0.85) or young females (1.56+/-1.96) at 21 days. While a significant increase in CTX-1 levels was detected in the blood plasma of aged females when compared to young females, P1NP levels did not significantly change between young and older females. No significant changes were observed for males. In conclusion, this study demonstrated that age and gender can significantly affect craniofacial bones, especially the maxilla and mandible in females. Considering the altered bone resorption parameters and delayed alveolar bone healing in older female mice, careful deliberation is necessary during the development of pre-clinical models for craniofacial research.

Loss of Prdm16 in LepRCre-expressing cells and their descendants does not alter radiation-induced marrow adiposity *Kiana Gunn[1], Wendi Guo[1], Kassandra Spiller[1], Cahil Potnis[1], Colleen Wu[1]. [1]Department of Duke Orthopaedic Surgery, United States

Radiotherapy is received by over 50% of cancer patients as a curative or combinatorial treatment modality. However, an adverse outcome of radiotherapy is the structural weakening of nearby bone, which can lead to bone-related complications like radiation-induced fractures that negatively impact the quality of life of long-term survivors of disease. Radiotherapy induces dramatic changes within cells residing in the bone microenvironment including depleting osteoblasts and expanding marrow adipocytes. Drugs that target the bone remodeling unit are minimally effective in preventing fracture risk for this patient population; therefore, we seek to investigate the mechanisms driving radiation-induced marrow adipocyte expansion.The molecular mechanisms regulating marrow adiposity are poorly understood. Interestingly, gene expression studies show that marrow adipocytes express brown/beige adipocyte-specific markers such as Prdm16. Notably, Prdm16 is required for not only the development and function of brown/beige adipocytes, but also for the regulation of skeletal stem cell proliferation and differentiation. For these reasons, we sought to elucidate the contribution of Prdm16 within skeletal progenitor cells during radiation-induced marrow adipocyte expansion.For this purpose, we utilized the LepRCre driver, as LepRCre-expressing cells label a population of post-natal skeletal progenitor cells found in the bone marrow stroma. Indeed, consistent with previous studies, confocal analysis of LepRCre;Rosa26tdTomato/+ reporter mice revealed marrow adipocytes labeled by tdTomato. Next, we generated LepRCre(-) control and LepRCre;Prdm16fl/fl mutant mice and exposed both cohorts to 4Gy total body irradiation (TBI). qPCR analysis of bone marrow stromal cells revealed diminished Prdm16 mRNA levels in mutant mice when compared to controls demonstrating efficient Cre-mediated recombination, thus validating our murine model. MicroCT and histological analysis of long bones revealed that loss of Prdm16 in LepRCre-expressing cells and their descendants did not attenuate radiation-induced marrow adiposity. In summary, we have shown that loss of Prdm16 in LepRCre-expressing cells and their descendants does not influence adipose volume post-irradiation. This data expands our knowledge of the underlying cellular and molecular mechanisms of radiation-induced marrow adiposity.

The Role of Clec3b+ Muscle Cells in Fracture Healing and Heterotopic Ossification *JACOB MOORE[1], EZGI AYDIN[2], Ugur Ayturk[2, 1], . [2]Hospital for Special Surgery, United States

Loss of Clec3b expression results in impaired healing of bone, connective tissue and skin injuries. We previously generated a Clec3b.creERT2 knock-in allele and found that Clec3b+ cells are located in muscle, outer periosteum and connective tissues, and are completely absent in the marrow, endosteum or growth plate. Further, Clec3b+ cells are osteogenically inactive during skeletal development and remodeling, but can contribute to the healing of drill hole injury or BMP2-driven heterotopic ossification (HO).Our goal with the current study was to determine the specific cell types Clec3b+ cells can convert to in trauma situations, and whether these changes are physiologically significant. We induced stabilized long bone fractures in Clec3b.creERT2; Ai14.R26.tdTomato; Bglap.eGFP mice. Using scRNA-seq, flow cytometry and fluorescent histology, we confirmed that Clec3b-lineage cells become fibroblasts, chondrocytes, osteoblasts, osteocytes, and bone marrow stromal cells in the fracture callus. To determine whether these Clec3b-lineage cells arise from the muscle or periosteum, we performed periosteum removal and bone graft transplantation experiments. All results indicated that muscle-resident Clec3b+ cells are the predominant contributors to bone healing. To test the significance of these contributions, we ablated Clec3b+ cells in Clec3b.creERT2; R26.DTA mice during fracture healing. MicroCT analysis showed that Clec3b+ cell-depleted fracture calluses had less bone volume (BV) than same-sex, littermate controls ($p < 0.05$).To determine whether Clec3b+ cells also play a significant role in HO, we activated the Acvr1.Q207D mutation in Clec3b+ cells (which results in BMP-gain-of-function) and confirmed muscle mineralization with microCT. To test loss of function, we depleted Clec3b+ cells with the DTA allele after inducing HO by intramuscular BMP2-injection. Surprisingly, Clec3b+ cell depletion (confirmed by histology) did not reduce but instead increase ectopic bone volume (both TV and BV, $p < 0.05$). These data suggest that Clec3b+ cell apoptosis during HO stimulates bone formation by cells that do not undergo Cre-recombination, either due to inefficient Cre-activation or lack of Clec3b-expression.Overall, our data show that Clec3b+ interstitial muscle cells play significant roles in regenerative and pathologic bone formation processes. Studying the mechanisms regulating Clec3b+ cells can lead to new strategies to promote fracture healing and prevent HO.

Identification of LRP1+ human periosteal skeletal stem cells with distinct osteochondrogenic potentials *YOUNGJAE JEONG[1], Lorenzo Deveza[2], LAURA ORTINAU[3], John Dawson[2], Dongsu Park[2, 1], . [2]Baylor College of Medicine, United States. [3]University of Missouri-Columbia,

Human skeletal stem cells (SSCs) are essential for lifelong bone maintenance and repair, and their multipotent differentiation capability to bone, adipocyte, cartilage, and marrow stromal cells makes promising therapeutic options for degenerative bone disorder and bone defects. However, due to heterogeneity and lack of selective markers, it is challenging to identify and isolate rare SSCs. In particularly, the molecular characteristics, function, and regulation of human periosteal SSCs in bone regeneration and repair is not clearly elucidated. Here, using single cell sequencing of human periosteal tissues, we found that the human periosteum contains multiple progenitor clusters and two SSC clusters (PTHRP+ and PTHRP-) expressing known SSC markers, PDPN and CD13. In particular, human periosteal SSCs, but not bone marrow SSCs, have selective expression of a new marker, LRP1 with high expression of Wnt, Notch, and BMP pathway genes. Further, single cell, immunostaining, and FACS analyses of mouse periosteum revealed that Prx1+ mouse P-SSCs also selectively express LRP1. When cultured at single cell level, LRP1+ human P-SSCs are highly clonogenic and long-term repopulating cells with osteochondrogenic but little adipogenic differentiation abilities. Notably, these human P-SSCs reside in perivascular location of human periosteum and repopulate in vivo upon transplantation into immunocompromised mouse calvaria injury. Taken together, our study demonstrates that adult human periosteum contains unique osteochondrogenic stem and progenitor cell subsets and LRP1 is a unique novel marker for endogenous human and mouse P-SSC subsets.

Ctdnep1 deletion in the Cathepsin K-expressing progenitor in the tendons and periosteum causes osteochondroma *Takuto Konno[1], Chisato Sampei[2], YASUHIRO ARASAKI[2], Takashi Nakamura[3], Shigeaki Kato[4], Ryuichi Nishinakamura[5], Yoshinori Asou[6], Yoichi Ezura[7], Tadayoshi Hayata[8]. [1]Tokyo University of Science, Japan. [2], Japan. [3]Department of Biochemistry, Tokyo Dental College, Japan. [4]Iryo Sosei University, Japan. [5]Department of Kidney Development, Institute of Molecular Embryology and Genetics, Kumamoto University, Japan. [6]Tokyo Medical and Dental University, Japan. [7]Tokyo Medical and Dental University, Medical Research Insititute, Japan. [8]Graduate School of Pharmaceutical Sciences and Faculty of Pharmaceutical Science, Tokyo University of Science, Japan

Osteochondroma and fibrodysplasia ossificans progressiva with heterotopic bone and cartilage formation significantly reduce patients' quality of life due to pain and decreased range of motion in the lesion. Recently, cells labeled with Cathepsin K-Cre have been reported to exhibit stemness and ectopic ossification potential in the tendons and periosteum. However, it is not well understood how the ectopic ossification potential of Cathepsin K-Cre-positive cells is suppressed in vivo to maintain tendon and periosteal homeostasis. The CTD nuclear membrane phosphatase Ctdnep1 is a negative regulator of TGF-?/BMP signaling and plays an essential role in endochondral ossification and ovary and kidney homeostasis in mice. Somatic mutations in CTDNEP1 in humans also cause hyperphosphorylation of MYC and genomic instability, leading to medulloblastoma. However, the roles of Ctdnep1 in osteochondroma remain elusive. Here we show that Ctdnep1 suppresses excessive cell proliferation and heterotopic ossification in Cathepsin K-Cre-positive cells in the tendon and periosteum. Deletion of the Ctdnep1 gene in cells positive for Cathepsin K-Cre causes osteochondroma around joints of the ankles and wrists but not those of the knees and elbows. Cathepsin K-Cre; Ctdnep1 (flox/flox) mice showed a marked gait disturbance with a shorter body length and contractures of the wrist and ankle joints. Skeletal preparation showed cartilage masses around the wrist and ankle joints. Micro CT analysis revealed ectopic ossification with low bone mineral density. Histological analysis revealed bone marrow formation in the lesions, suggesting that ectopic endochondral ossification occurred. Gene expression analysis showed that the expression of marker genes for cartilage, tendon, and osteoclasts was significantly elevated in lesions. Furthermore, cell lineage analysis combining fluorescent reporter mice with the CUBIC tissue clearing technique revealed that osteochondromas originated from Cathepsin K-Cre-positive cells, which were positive for phosphorylated Smad2 and Sox9, suggesting that Cathepsin K-Cre-positive progenitor cells transdifferentiated into chondrocytes. Our results demonstrate that Ctdnep1 is a suppressor of transdifferentiation-mediated tumor development in Cathepsin K-Cre-positive progenitor cells in the tendon and periosteum.

Periosteal CD51+ progenitor cells contribute to local healing *YE CAO[1], IVO KALAJZIC[2], Brya Matthews[3, 1], New Zealand, [2]University of Connecticut Health Center, United States, [3]University of Auckland, New Zealand

The periosteum is a major source of cells that contributes to fracture healing. However, complexity of the fracture model includes response of bone marrow derived skeletal stem/progenitor cells (SSPCs). In this study, we evaluated the response of periosteum and defined populations of periosteal injury-responsive SSPCs using a periosteum-specific scratch injury.Following injury, periosteal progenitors expanded by day 3 and formed fibrocartilage by day 7. Fibrocartilage was gradually replaced by new bone formation with marrow infiltration from day 14 to day 21. Bone and periosteum were remodeled, and healing was complete by day 28.We used multicolor spectral flow cytometry combined with ?SMACreER/tdTom/Col2.3GFP, a lineage tracing model of skeletal progenitors (?SMA+) and osteoblasts (Col2.3+). Within total periosteal CD45- cells, enrichment of ?SMA and CD90 cells was detected on day 3 (10.4% and 27.9%) and day 7 (28.0% and 36.0%) after injury compared with uninjured (3.4% and 17.9%). Markers of progenitors Sca1+CD51+, Sca1-CD51+ were expanded by 7 days after injury.Histologically, most periosteal Sca1 cells were located on the outer periosteum layer. They showed minimal expansion with injury. CD51 and CD90 cells were more abundant in the inner layer and expanded immediately with injury. In contrast with flow result, Sca1+CD51+ cells were rare in the periosteum in situ. Some CD51+ cells were Col2.3+ on day 14 following injury, indicating the contribution of CD51+ cells to osteoblasts.Periosteal Sca1+CD51+ cells were multipotent, and Sca1-CD51+ cells were committed osteoprogenitors in vitro. We further examined the in vivo lineage potential of Sca1-CD51+ and, Sca1+CD51+ cells by subcutaneous transplant. In contrast to the in vitro results, Sca1-CD51+ cells exhibited greater engraftment and more osteoblast formation than the other populations tested.Stimulation of Notch signalling enhances bone healing. Using ?SMACreNICD mice, which have increased Notch signalling in ?SMA+ cells, we found the frequency of CD51+ was tripled in NICD+ mice compared to controls, indicating that CD51+ cells may improve healing at early stages.In conclusion, periosteal Sca1-CD51+ and CD90+ cells are multipotent progenitors that respond rapidly to local injury in vivo. Enhanced bone healing is correlated with the rapid expansion of CD51+ osteoprogenitors.

The role of BMP2 in periosteal cell behavior and appositional bone growth *Emily Moore[1], David Maridas[1], Laura Gamer[1], Gavin Chen[1], Ana Garcia Castineiras[1], Kathryn Burton[1], Vicki Rosen[1]. [1]Harvard School of Dental Medicine, United States

The periosteum contains stem/progenitor cells capable of differentiating into cells that contribute to bone growth and repair. Bone morphogenetic protein (BMP) signaling is central to the activation and differentiation of periosteal cells. Mice lacking periosteal BMP2 (Bmp2fl/fl;Prx1Cre) have significantly thinner bones as early as 2 weeks of age and are unable to initiate fracture repair. Here, we investigate the unique phenotype resulting from removal of BMP2 in periosteal lineage cells. Bulk RNAseq analysis of periosteum verified that osteogenesis and BMP signaling were downregulated in Bmp2fl/fl;Prx1Cre mice at birth, consistent with reduced periosteal activity. To further interrogate periosteal BMP signaling in appositional growth, we designed an ex vivo growth model. Briefly, femurs from P7 littermates were exposed to oscillatory fluid flow (FF) using a custom femur holder and platform rocker for 5 consecutive days. Bmp2fl/fl femurs were slightly longer compared to Bmp2fl/fl;Prx1Cre femurs under static conditions and FF did not influence length. Femurs from control mice widened significantly and BMP signaling was upregulated when FF was applied, but this behavior was lost in Bmp2fl/fl;Prx1Cre explants. Histological analysis revealed the cambium layer of the periosteum expanded, bone formation was enhanced, and BMP signaling was upregulated in the mid-diaphysis with FF in controls. The periosteal surface was comparatively inactive in Bmp2fl/fl;Prx1Cre femurs. To further investigate the role of BMP signaling in periosteal cell behavior, we generated a periosteum-derived cell line that expresses established periosteal markers, engages in BMP signaling, and differentiates into chondrocytes and osteoblasts. When treated with BMP2, these cells demonstrate accelerated osteogenic differentiation. We also confirmed these cells are mechanoresponsive using a custom chamber apparatus to apply FF. BMP signaling was not upregulated in response to FF, but Smad1 levels and Bmp2 mRNA expression significantly increased. We speculate that, in response to FF, periosteal cells are priming for BMP signaling to facilitate osteogenic differentiation. This work is the first to suggest a role for BMP signaling in periosteal cell mechanotransduction and we speculate that BMP2 is important for this process. Collectively, we anticipate that our bulk dataset and novel experimental tools will greatly advance our understanding of periosteal activity and subsequent bone formation.

AdipoQ lineage bone marrow progenitors are the major cellular source of M-CSF for bone marrow macrophage development, osteoclastogenesis and bone metabolism *Yongli Qin[1], Kazuki Inoue[1], Yuhan Xia[1], Jie Han[2], Ruoxi Yuan[3], Jun Sun[4], Ren Xu[2], Jean X. Jiang[5], Matthew B. Greenblatt[1], Baohong Zhao[1]. [1]Weill Cornell Medical College and Hospital for special surgery, United States, [2]The first Affiliated Hospital of Xiamen University, China, [3]Hospital for special surgery, United States, [4]Weill Cornell Medical College , United States, [5]University of Texas Health Science Center, United States

M-CSF, encoded by Csf1, is a critical growth factor for myeloid lineage cells, including monocytes, macrophages, and osteoclasts. Tissue-resident macrophages in most organs rely on local M-CSF. However, it is unclear what specific cells in the bone marrow produce M-CSF to maintain myeloid homeostasis. We performed an integrative scRNAseq analysis based on five published bone marrow scRNAseq datasets and human bone marrow scRNA-seq datasets. Although the current paradigm indicates osteoblasts as the main cellular source of M-CSF in bone marrow, we surprisingly found that the osteoblasts do not express Csf1 in vivo. In contrast, we identified that Adipoq-lineage (Adipoq+) bone marrow progenitor cells possess the predominant and highest Csf1 expression level in bone marrow. The Adipoq-lineage progenitors with high CSF1 expression also exist in human bone marrow. We further generated Csf1 conditional knock out (cKO) mice, in which Csf1 is specifically deleted in Adipoq+ cells by crossing Csf1flox/flox mice with Adipoq-cre mice (hereafter referred to as Csf1?Adipoq). Csf1 deficiency in Adipoq+ cells lead to a drastic decrease in bone marrow macrophages and a severe osteopetrotic phenotype in mice with significantly reduced osteoclast numbers and enhanced bone mass. Without exogenous M-CSF, RANKL is able to induce osteoclastogenesis in bone marrow harvested from the control mice, but not from Csf1?Adipoq bone marrow. These results further support an essential role for M-CSF secreted from Adipoq+ bone marrow cells in osteoclastogenesis in vivo. Interestingly, Csf1 is undetectable in other Adipoq highly expressed cells, including peripheral mature adipocytes or mature bone marrow adipocytes. Tissue macrophages in other organs appear normal in Csf1?Adipoq mice. Furthermore, the lack of the Adipoq+ cell-produced M-CSF prevented the estrogen-deficiency induced excessive osteoclast formation and osteoporosis, indicating a potential novel therapeutic strategy for postmenopausal bone loss by targeting M-CSF produced by Adipoq+ cells. Collectively, our data reveal a specifically high Csf1 expression feature of the Adipoq+ bone marrow progenitor cells. These cells constitute approximately only 0.05% of bone marrow cells, but are the major cellular source of M-CSF in bone marrow. These findings challenge the current paradigm and have profound implications for our understanding of bone marrow macrophage development, osteoclastogenesis, bone homeostasis, and pathological bone loss.

SUN-278

EPDR1 Governs Metabolic and Immunologic Re-programming of Human Mesenchymal Stem Cells During Osteoblast Differentiation *Yadav Wagley[2], Tristan Maerz[2], James A. Pippin[3], Matthew C. Pahl[3], Alessandra Chesi[4], Andrew D. Wells[4], Struan Grant[5], Kurt Hankenson[2]. [2]University of Michigan, , [2]University of Michigan, United States, [3]Center for Spatial and Functional Genomics, United States, [4]Department of Pathology and Laboratory Medicine, United States, [5]Children s Hospital of Philadelphia / University of Pennsylvania, United States

EPDR1 is a novel human osteoblast regulatory gene previously identified by intersecting BMD GWAS datasets with promoter-focused Capture-C and ATAC-seq generated in differentiating human osteoblasts. Recently, we showed that the open chromatin region harboring the BMD variants rs1524068, rs6975644 and rs940347 functions as an osteoblast specific EPDR1 enhancer in hFOB1.19 cells. However, the precise molecular processes controlled by EPDR1 is unknown. Herein, we knocked-down EPDR1 expression in three unique bone-marrow derived human mesenchymal stem cell donor lines (hMSC) using small interfering RNA and evaluated the global transcriptomic changes with or without BMP2 stimulation using osteopermissive media. Globally, 3,861 genes were differentially regulated (1,888 upregulated and 1,973 downregulated) by BMP in non-targeted cells, whereas 2,744 genes were differentially regulated (1,528 upregulated and 1,216 downregulated) in EPDR1 silenced cells. As expected, genes associated with osteoblast differentiation, BMP signaling pathway, Notch signaling pathway and tissue morphogenesis were expressed in non-targeted cells; however, none of these biological processes achieved significance in EPDR1 silenced cells, suggesting major pathway perturbations. To understand these changes, we performed a donor-specific comparison with EPDR1-silenced cells. Of the ~2,300 genes differentially regulated, we observed an upregulation of genes related to inflammatory response, cytokine-mediated signaling pathway, and regulation of T cell activity, while genes related to cell division were decreased. Additionally, we observed differentially expressed genes enriched for pathways involved in regulation of fatty acid metabolic process, regulation of bone resorption, arachidonic acid metabolic process, negative regulation of collagen biosynthetic process and positive regulation of tumor necrosis factor, interferon-gamma, and interleukin-8 production upon BMP2 stimulation. The crystal-structure of EPDR1 protein suggests human EPDR1 folds into a dimer using a monomeric subunit consisting of a deep hydrophobic pocket to bind to hydrophobic fatty acids and function as a lipoprotein carrier. Since EPDR1 is a secreted protein, an immune-reactive profile driven by loss of EPDR1 could be metabolically mediated via disturbances in cellular lipoprotein and fatty acid trafficking. We

conclude that EPDR1 could play an important role in pathophysiological bone turnover later in life and therefore warrants further investigation.

SUN-279

In Vivo Tracking of Human Fetal Skeletal Stem Cell Lineage Dynamics at the Single Cell Level *Thomas Ambrosi[1], Rahul Sinha[2], Charles Chan[2]. [1]UC Davis, United States. [2]Stanford University, United States

With the increasing socioeconomic impact of skeletal disorders and the absence of reliable treatments, innovative approaches are required to prevent bone loss and restore skeletal tissues. Skeletal stem cells (SSCs) show great potential as a new therapeutic option; however, progress has been hindered by a lack of understanding regarding the identity and function of these cells in humans. Here, we utilized a combination of prospective flow cytometric isolation and SmartSeq2 single cell RNA-sequencing (scRNAseq) to interrogate the diversity of over 4,000 human SSCs from ten distinct skeletal sites at 20 weeks gestational age. In vivo tracing of lentivirally barcoded fetal human SSCs was combined with scRNA-seq readouts to assess unique clonal dynamics of human growth plate and periosteal SSCs. RNAscope was employed to map SSC subsets in situ. A xenograft model of fetal skeletal elements together with scRNAseq was used to further deconstruct the human SSC lineage tree in fetal long bones. Transcriptomic analysis of single fetal SSCs from distinct skeletal sites revealed diversity of SSCs tied to specialized features correlating with anatomical localization. Intriguingly, gene expression in specific types of SSCs residing in different bone regions was linked to skeletal phenotypes caused by genetic mutations. For example, XYLT1, a gene that if mutated leads to dwarfism, was highly expressed in growth plate SSCs but not cranial, periosteal, pelvic or vertebra SSCs, while SEC24D, a gene associated with craniosynostosis, was highly expressed in suture SSCs. Overall, we identified two major types of SSCs - an osteochondral SSC and a stromal SSC. We also found that growth plate and periosteal SSCs of long bones, representing examples of the two specialized SSC subtypes, presented with distinct clonal dynamics thereby differentially contributing to skeletal development. Functional and bioinformatic approaches highlighted that neither of the two SSC types were dispensable and that they tightly interacted to facilitate proper bone growth and maintenance. Lastly, index-sort analysis of prospectively isolated SSC lineage subsets was able to reconstruct stem cell dynamics and identify additional new subsets of specified, more committed skeletal lineage cell populations. In summary, our research provides novel insights into human skeletal stem cell biology and offers experimental vantage points to study skeletal development and disease at an unprecedented resolution.

Mesenchymal stem cell (MSC) differentiation into osteoblasts is regulated through precise molecular mechanisms that are well positioned to impact bone phenotypes. With aging, both the number of MSCs and their differentiation potential into osteoblasts declines. Concurrently, inflammaging-driven mechanisms increase metabolism of tryptophan into kynurenine (Kyn), which we have previously shown is detrimental to osteoblastic bone formation both in vitro and in vivo. The aryl hydrocarbon receptor (AhR) is best known as a receptor for environmental toxicants, acting as a transcription factor which drives expression of metabolic enzymes such as cytochrome P450 family 1 subfamily A member 1 (CYP1A1). AhR has been reported to be activated by Kyn, but the extent to which other tryptophan metabolites further downstream in the Kyn pathway activate AhR signaling has not yet been tested.We obtained a luciferase reporter vector incorporating the canonical AhR response element (5'-GCGTG-3') and investigated activation of canonical AhR signaling by various tryptophan metabolites in the Kyn pathway. Of the nine compounds tested, only tryptophan, Kyn, and 3-hydroxy-Kyn (3HK) dose-dependently activated AhR transcriptional activity in C2C12 and ST2 mesenchymal cells, with 3HK being the most potent activator. Results were verified by qPCR for CYP1A1, and a time-course study revealed that CYP1A1 expression peaked after 3 hours of Kyn treatment. The metabolism of tryptophan to Kyn, and Kyn to 3HK was inhibited using pharmacological inhibitors of Indoleamine 2,3-dioxygenase (IDO) and Kyn-3-monooxygenase enzymes (KMO) enzymes. These experiments suggested that metabolites downstream of Kyn could mediate negative effects on MSCs. In fact, MTT and TUNEL assays demonstrated significant cell death following treatment of MSCs with 3HK and 3-Hydroxyanthranilic acid (3HAA). Interestingly, cell death was rescued upon scavenging reactive oxygen species with N-acetyl cysteine, suggesting that the mechanism of cell death was attributable to increased oxidative stress. With regards to bone formation activity, the differentiation of MSCs into matrix-producing osteoblasts was blunted upon the introduction of Kyn, 3HK and 3HAA into the osteogenic differentiation media. Together, these results suggest that several intermediate metabolites in the tryptophan-Kyn pathway impede the differentiation of MSCs into osteoblasts through inducing reactive oxygen species leading to apoptosis.

SUN-281

Effect of Abaloparatide and Teriparatide on Ctsk+ Periosteal Stem Cells and Cortical Responses *Dhairya Raval[1], Ruiying Chen[1], Dorothy Hu[1], Shawn Berry[1], Lama Alabdulaaly[1], Beate Lanske[2], Roland Baron[3], Francesca Gori[1]. [1]Harvard School of Dental Medicine, United States. [2]Radius Health, Inc., United States. [3]Harvard Medical School and School of Dental Medicine, United States

The periosteum contains a niche of stem cells and progenitors, which contributes to cortical expansion during growth, homeostasis and repair in adults, and responds to anabolic drugs. PTH(1-34) (Teriparatide, TPTD) and the PTHrP analog (Abaloparatide, ABL) are FDA-approved anabolic therapies for osteoporosis. Pre-clinical and clinical studies suggest however, that their influence on the periosteal surface somehow differ, with ABL exerting stronger effects than TPTD. Here we investigated whether ABL and TPTD regulate differentially the periosteal stem cell niche, focusing in particular on periosteal Ctsk+ cells, which include stem cells (PSCs) and non-stem progenitors (PP1 and PP2) and play an important role in periosteal biology. To this aim, 6 weeks old CtskCre;mTmG female mice, in which Ctsk+ cells are GFP+, were treated with vehicle, TPTD or ABL (40ug/kg/day, 5d/week) for 4 weeks. Ctsk+ PSCs, PP1 and PP2 cells were isolated and analyzed by flow cytometry. ABL increased significantly the % of the Ctsk+ PSC population (p=0.015), while TPTD did not significantly affect this stem cell population. While PP1 and PP2 cells were not significantly affected by either treatment, both treatments significantly favor their differentiation into osteo-chondro lineage cells (Lin-THY1.2+6C3-GFP+CD105+) (p=0.01). These data suggest that ABL leads to an accumulation of Ctsk+ PSCs and favor their differentiation, while TPTD favors Ctsk+ periosteal cell differentiation into the osteo-chondro-lineage, w/o affecting the PSC population. Dynamic histomorphometry analysis of cortical bone indicates that both treatments lead to a significant increase in periosteal MS/BS and periosteal BFR/BS. Confirming an increase in periosteal bone apposition, cortical TV and BV/TV, measured by mCT analysis, were significantly increased by both treatments, while cortical thickness was significantly increased only by ABL. Our data raise the possibility that Ctsk+ periosteal cells respond to both TPTD and ABL and that, at the dose of 40 ug/kg/day, ABL, but not TPTD treatment significantly increase the % of Ctsk+ periosteal stem cells. Further understanding of the effects of anabolic agents on periosteal stem cells may have clinical implications for fracture repair and the treatment of diseases associated with bone fragility.

Mitochondrial Metabolism Determines Mesenchymal Stem Cell Fate *CHEN YU[3], RUBENS SAUTCHUK JR[2], Roman Eliseev[3]. [3]University of Rochester, , [2], , [3]University of Rochester, United States

Aging-related changes in bone marrow stromal (a.k.a. mesenchymal stem) cells (BMSCs) shift cell fate away from osteogenesis and towards adipogenesis. The mechanism(s) underlying such changes are not completely understood. Mitochondria are important cell organelles that not only produce energy but also determine cell behavior by regulating metabolism, signaling, calcium homeostasis, apoptosis, and other cellular processes. We have previously shown that mitochondrial activation is important during osteogenesis of BMSCs. In aged bone tissue, we observed pathological opening of the mitochondrial permeability transition pore (mPTP) which leads to mitochondrial dysfunction, oxidative phosphorylation uncoupling, and cell death. Cyclophilin D (CypD) is a mitochondrial protein that facilitates opening of the mPTP. We found that CypD is downregulated during osteogenesis of BMSCs leading to lower mPTP activity and, thus, protecting mitochondria from dysfunction. On the other hand, we observed that during adipogenesis, BMSC alternative fate, cells significantly upregulate glycolysis and increase CypD expression and mPTP activity. Confocal imaging shows that mitochondrial morphology remains rounded and fragmented during this process (Figure). CypD gene, Ppif, promoter analysis reveals multiple binding sites for adipogenic C/EBP and inflammatory NF-?B transcription factors. Luciferase assay and ChIP-PCR analysis confirm C/EBP? as a transcriptional activator of CypD. NF-?B p65 translocates to the nucleus during adipogenesis and shows synergistic effect with C/EBP? in inducing Ppif expression, suggesting a potential link between 'inflammaging' and altered BMSC fate. In vitro CypD overexpression enhances, whereas CypD knockdown impairs adipogenesis.

Pharmacological inhibition of CypD by NIM811 also impairs adipogenesis in vitro. Prx-1Cre-mediated deletion of CypD in Ppiff/f mice decreases bone marrow fat in 13-month-old mice. Currently we are pursuing the effect of Prx1Cre-mediated CypD overexpression in mice. In summary, BMSCs maintain or upregulate CypD expression during adipogenesis leading to increased mPTP activity, activated glycolysis and low mitochondrial function, thus establishing a metabolic profile that appears to be favorable for adipogenic lineage. The overall goal of this study is to define the potential role of CypD/mPTP during BMSC adipogenesis, facilitating the understanding of stem cell fate determination and molecular mechanism of age-related bone loss.

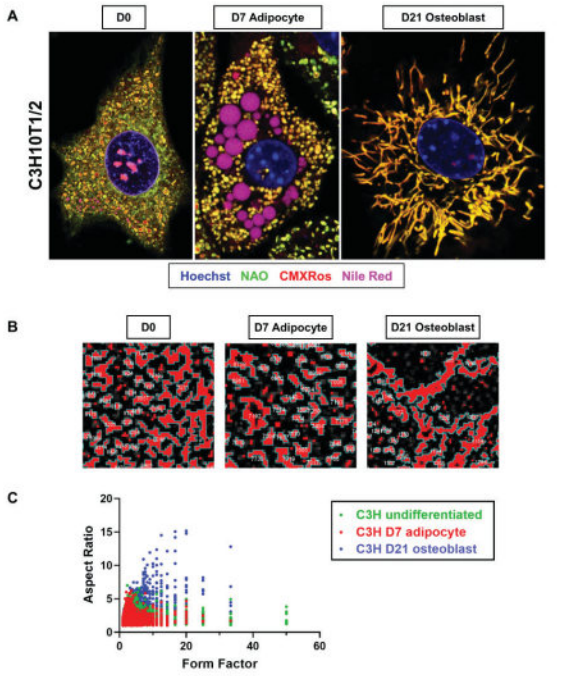

Figure. Mitochondrial network during osteogenesis and adipogenesis in C3H10T1/2.
A) Representative images of mitochondrial morphology in C3H/10T1/2 cells. Cells were cultured in adipogenic media for 7 days or osteogenic media for 21 days. After staining, images were taken by confocal microscopy at 63x magnification. B) Representative images of mitochondrial morphology analysis in C3H10T1/2. Analysis was performed with CMXRos staining using ImageJ. C) Quantification of mitochondrial morphology. For each group, three cells were randomly selected for analysis.

Effect of vitamin D on biochemical markers of bone turnover in people with prediabetes *Lisa Ceglia[1], Saul Malozowski[2], Richard Pratley[3], Irwin Brodsky[4], Erin Leblanc[5], Edith Angellotti[6], Jason Nelson[6], Ellen Vickery[6], Anastassios Pittas[6]. [1]Tufts Medical Center Tufts University, United States. [2]NIH, United States. [3]Advent Health, United States. [4]Maine Health, United States. [5]Kaiser Permanente, United States. [6]Tufts Medical Center, United States

Background: People with glucose intolerance have altered bone turnover, including diminished postprandial suppression of bone resorption. Whether vitamin D can impact bone turnover markers in people with prediabetes has not been studied.Objectives: To determine the effects of vitamin D3 4000 IU/d on 12-month changes in fasting and post-oral glucose tolerance test (OGTT) serum C-telopeptide (CTX) levels, fasting serum procollagen 1 intact N-terminal propeptide (P1NP) and osteocalcin (OC) levels, and fasting serum intact parathyroid hormone (PTH) levels in adults with prediabetes.Research design and methods: This is a post-hoc analysis in a subset of the vitamin D (n=274) and placebo (n=287) groups of the vitamin D and type 2 diabetes (D2d) study - a trial conducted to evaluate whether vitamin D3 lowers risk of diabetes in people with prediabetes. Participants were included in the analysis if they had a baseline and 12-month 75-gram OGTT begun before 9am (to avoid diurnal variation effects on bone turnover) and did not have either a fracture or exposure to osteoporosis drug therapy. Serum was collected at 0', 30', and 120' after the glucose load. Results: At baseline, 41% were women, mean+/-SD age was 59+/-9 y, hemoglobin A1c was 5.9+/-0.2%, and serum 25-hydroxyvitamin D (25OHD) was 28.0+/-9.5 ng/mL. Baseline characteristics of the two groups did not differ. Serum 25OHD increased by a mean 24.3 ng/mL [95%CI 23.1,25.5] with vitamin D vs. 0.2 ng/mL [-1.0,1.4] with placebo at 12 months. PTH levels decreased in response to vitamin D (-3.9 pg/mL [-5.4,-2.5] with vitamin D vs. 0.7 pg/mL [-0.7,2.1] with placebo). CTX rose over 12 mo in both groups, but with >90% power to detect a 15% group difference, we found no statistically significant differences in % change in fasting CTX (6.3% [0.2,12.3] with vitamin D vs. 6.6% [0.6,12.6] with placebo) or in the area under the CTX curve post-OGTT (CTXAUC) (24.2% [-13.6,61.9] with vitamin D vs. 31.2% [-6.4,68.7] with placebo), with or without adjustment for age, gender, race, and baseline calcium intake, 25OHD, and CTX. A subgroup analysis of those aged >=60 y also showed no significant differences between groups. Twelve-month changes in serum P1NP and OC did not differ significantly by group.Conclusion: In a relatively healthy population of people with prediabetes, 4,000 IU/d of vitamin D3 raised 25OHD and lowered PTH levels but had no significant effect on circulating bone turnover markers.

Protein Intake by Source and Longitudinal Measures of Bone Strength at the Distal Radius and Tibia *Lisa Langsetmo[1], Sameneh Farsijani[2], Nicole M Sekel[2], Aarohee P Fulay[2], Jane A. Cauley[3], Kristine Ensrud[4], John Schousboe[5], Andrew Burghardt[6], James M Shikany[7]. [1]Minneapolis VA Medical Center, United States. [2]University of Pittsburgh, United States. [3]UNIVERSITY OF PITTSBURGH, United States. [4]University of Minnesota and Minneapolis VA Health Care System, United States. [5]Park Nicollet Clinic HealthPartners Institute University of Minnesota, . [6]University of California, San Francisco, United States. [7]University of Alabama at Birmingham, United States

We have shown in cross-sectional analysis that dietary protein intake (by source) among older men is associated with high resolution peripheral quantitative computed tomography (HR-pQCT) parameters. It is unclear whether these associations persist over time. Our aim was to assess whether the dietary intake of protein (by source) is related to both baseline and follow-up measures of estimated failure load, as assessed by HR-pQCT, among Osteoporotic Fractures in Men (MrOS) study participants. Men were included who had food frequency questionnaire total energy intake (TEI) between 500 and 5000 kcal/d at visit 4 (2014 -16) and repeat distal radius or tibia HR-pQCT scans at visit 4 and visit 5 an average of 5.9 years later (2019 -22). Two-dimensional registration was used to ensure common region of interest. We used mixed effect regression models to determine the association between protein intake (expressed as % of TEI) and failure load at baseline and follow-up, with both exposure and outcome modeled as continuous variables. Models were adjusted for age, race/ethnicity, visit, center, TEI, education, limb length, smoking, alcohol intake, physical activity level, corticosteroid use, supplement use (calcium and vitamin D), and osteoporosis medications. The study sample included 166 eligible men with mean (SD) age 83.2 (3.2) y, mean TEI of 1505 kcal/d (16.3% protein), and mean (SD) failure load of 6690 (1809) kN at visit 4. In fully adjusted models, non-dairy animal protein and plant protein were not associated with failure load of the distal radius or tibia. There was a consistent positive association between dairy protein and longitudinal HR-pQCT measures of failure load, which was statistically significant for both skeletal sites. While there was no statistically significant association of dietary protein by source with longitudinal change in failure load, there was also no evidence of attenuation of the cross-sectional association over time. In conclusion, higher dairy protein intake was associated with failure load consistent with previous findings and this association persisted among survivors almost 6 years after initial assessment of protein intake.

	Failure Load (kN)	
	Distal Radius	Distal Tibia
Dairy Protein	591 (135, 1047)	997 (25, 1968)
Non-Dairy Animal Protein	83 (-226, 392)	-112 (-758, 535)
Plant Protein	-8 (-526, 511)	122 (-988, 1232)

Adjusted for age, race/ethnicity, center, visit, education, limb length, smoking, alcohol intake, physical activity level, corticosteroid use, supplement use (calcium and vitamin D), and osteoporosis medications.

Beta-coefficient is increase in failure load per SD=3.0% of total protein intake.

Increased conversion of 25(OH)D to 1,25(OH)2D: A critical requirement for the maintenance of optimal status of active vitamin D metabolite in the context of vitamin D deficiency *Sudhaker Rao[1], Shijing Qiu[1]. [1]Henry Ford Hospital, United States

The active vitamin D metabolite, 1?,25-dihydroxyvitamin D (1,25(OH)2D), is converted from its substrate, 25-hydroxyvitamin D (25(OH)D). This process implicates a positive correlation existing between 25(OH)D and 1,25(OH)2D levels. However, it has been found that many healthy individuals suffering from 25(OH)D deficiency have optimal 1,25(OH)2D levels. The underlying mechanism(s) is not clearly understood.In the current study we examined serum levels of 25-(OH)D, 1,25-(OH)2D, serum corrected calcium (CCa), Creatinine (Cr), and parathyroid hormone (PTH) in 46 heathy women aged 21-73 years. The conversion rate of 25(OH)D to 1,25-(OH)2D was calculated by the ratio of the two metabolites (1,25(OH)2D/25(OH)D). To reveal the percent conversion rate (%), we transformed the unit of measurement for 1,25(OH)2D from pg to ng. The differences in 25(OH)D, 1,25-(OH)2D and 1,25(OH)2D/25(OH)D were compared between subjects with and without vitamin D deficiency (25(OH)D <20 ng/mL) using student t test. In addition, the relationships of CCa, Cr and PTH with 25(OH)D, 1,25-(OH)2D and 1,25(OH)2D/25(OH)D were analyzed using Spearman's correlation coefficient.Among the 46 white women, 28 (61%) with 25(OH)D deficiency (<30 ng/mL). The distribution of dot plots in figure 1 indicated that 1,25(OH)2D/25(OH)D decreased with increasing 25(OH)D levels. Table 1 showed that BMI, 1,25(OH)2D/25(OH)D and PTH were significantly higher in subjects

with 25(OH)D deficiency than in those with 25(OH)D sufficiency. However, there were no significant differences in 1,25(OH)2D, CCa and Cr between the 2 groups. Both BMI and PTH were significantly negatively associated with 25(OH)D levels but positively associated with 1,25(OH)2D/25(OH)D ratio.The results indicated that 1,25(OH)2D level was not significantly decreased in healthy subjects with vitamin D (25(OH)D) deficiency. However, the conversion rate of 25(OH)D to 1,25(OH)2D is likely to increase with decreasing 25(OH) D levels. The potential mechanism is that the lower 25(OH)D levels stimulate PTH secretion, which promotes the conversion of 25(OH)D to 1,25(OH)2D. Since 1,25(OH)2D is the hormonally active vitamin D metabolite, its optimal levels may play a crucial role in the maintenance of mineral homeostasis and skeletal health, even in the context of vitamin D deficiency. Alternatively, the product inhibition of conversion may promote higher conversion rate in the presence of vitamin D deficiency.

Tabble 1. Comparison of age, BMI and biochemical variables between white women with deficient and optimal vitamin D levels

Group	25(OH)D (<30 ng) (n = 28)	25(OH)D (≥30 ng) (n = 18)	p
Age (years)	54.9 (14.1)	54.8 (14.1)	0.787
BMI	27.9 (5.73)	24.7 (3.71)	0.022
$1,25(OH)_2D$ (pg/mL)	34.0 (12.8)	31.4 (8.88	0.424
$1,25(OH)_2D/25(OH)D$ (%)	0.164 (0.072)	0.091 (0.030)	<0.001
Corrected Calcium (mg/dL)	9.44 (0.434)	9.36 (0.524)	0.549
Creatitine (mg/dL)	1.07 (0.186)	1.08 (0.165)	0.822
PTH (pg/mL)	34.8 (10.1)	27.6 (5.90)	0.004

Effect of GIP and GLP-1 infusion on bone resorption in adults with glucose intolerant, pancreatic insufficient cystic fibrosis *Wang Shin Lei[1], XianYan Chen[1], Lingyu Zhao[1], Bradley Phillips[1], Michael Rickels[2], Andrea Kelly[3], Joseph Kindler[4]. [1]University of Georgia, United States. [2]University of Pennsylvania Perelman School of Medicine, United States. [3]The Children's Hospital of Philadelphia, United States. [4]The University of Georgia, United States

Diabetes and bone disease are common complications of cystic fibrosis (CF) in which they primarily occur alongside exocrine pancreatic insufficiency (PI). Gut-derived "incretin" hormones, gastric inhibitory polypeptide (GIP) and glucagon-like peptide 1 (GLP-1), augment postprandial insulin secretion. In CF, PI dampens incretin response and loss of the insulinotropic effect of GIP was recently identified. Since GIP decreases bone resorption, we aimed to determine if GIP-mediated suppression of bone resorption is preserved in individuals with PI-CF. We performed a secondary analysis of specimens from a double-blinded randomized placebo-controlled crossover trial in adults ages 18-40 years (n=22) with PI-CF that determined effects of intravenous infusion of incretins on pancreatic ?-cell response. Subjects were assigned to receive either GIP (4 pmol/kg/min) or GLP-1 (1.5 pmol/kg/min) infusion, along with a placebo infusion completed on a separate day. Three healthy adults without CF also completed testing during GIP and placebo infusions. Serum C-terminal telopeptide (CTX), a biomarker of bone resorption, was assessed before (mins -5 to 0) and during (mins 30 to 80) infusion. CTX incremental area under the curve (iAUC) during infusions was calculated. Effects of incretin infusion on CTX were tested using two-way repeated measures ANOVA with random effects for subject and subject by treatment interaction. CTX decreased significantly under the GIP vs saline condition in PI-CF (time by treatment interaction p<0.01; Fig. 1A). Although the time by treatment interaction was not significant in the three healthy adults (p=0.23), CTX decreased significantly during GIP infusion (p=0.03) but not saline infusion (p=0.50). In PI-CF, CTX-iAUC during GIP infusion was significantly negatively correlated with BMI (r=-0.69, p<0.05) and forced vital capacity (r=-0.64, p<0.05), and marginally negatively correlated with age (r=0.48, p=0.16) and forced expiratory volume (r=-0.58, p=0.08). GLP-1 did not affect CTX (Fig. 1B). These results suggest that the bone anti-resorptive effect of GIP is preserved in PI-CF. We were not powered to test differences between adults with PI-CF and controls, but our results indicate that the effect of GIP infusion on bone resorption might be moderated by nutrition status, pulmonary function, and age. Since the incretin response is perturbed in PI-CF, involvement of the "gut-bone axis" in CF-related bone disease requires further attention.

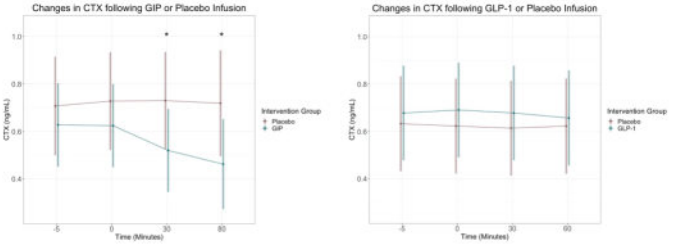

Fig. 1. CTX response to GIP (left) and GLP-1 (right) infusion in adults with PI-CF. Blue circles/bars represent the GIP/GLP-1 infusion and red circles/bars represent placebo (saline) infusion. Data are presented as means and 95% confidence intervals. *Corresponding timepoint during GIP/GLP-1 infusion differs significantly from min -5. CTX, carboxy-terminal collagen crosslinks; GIP, glucose-dependent insulinotropic polypeptide; GLP-1, glucagon-like peptide 1.

Daily Prune Intake, Bone Turnover Markers, and Bone Balance Are Associated with Changes in Bone Mineral Density in Postmenopausal Women: The Prune Study *Ana Carla C Salamunes[1], Janhavi Damani[1], Nancy I Williams[1], Connie M Weaver[2], Connie J Rogers[3], Cindy H Nakatsu[4], Mary Jane De Souza[1]. [1]Pennsylvania State University, United States. [2]San Diego State University, United States. [3]University of Georgia, United States. [4]Purdue University, United States

Background: The Prune Study (NCT02822378) is a 12-month randomized controlled trial (RCT) that investigated the effects of daily prune intake on bone health outcomes in postmenopausal women. We have previously reported that the daily intake of 50g of prunes preserved hip bone mineral density (BMD) (AJCN, 2022). In this analysis of the Prune Study, we aimed to determine (1) if changes in BMD were associated with changes in bone turnover markers (BTM), and (2) if bone balance (BB), calculated using algorithms (Bieglmayer et al., EJCI, 2009), was predictive of changes in BMD. Methods: Postmenopausal women were randomized into three study groups (SG): control group (n=78), 50g/day prune intake (n=79), and 100g/day prune intake (n=78). Dual-Energy X-Ray Absorptiometry scans assessed total body, total hip, femoral neck, and lumbar spine BMD. Fasted blood samples were obtained to assess serum levels of procollagen-1 intact N-terminal propeptide (P1NP) and C-terminal telopeptide (CTX). Changes in BMD and BTM are expressed as percent change from baseline to 12 months (%chg) in completers only (control group n=70, 50g n=67, 100g n=46). Median serum P1NP and CTX from healthy postmenopausal women (BMD T-scores >-1.0 at baseline) were used as the healthy reference values for the estimation of multiple of medians of bone formation (MOMf) and resorption (MOMr), calculated individually. BB was calculated as the ratio MOMf/MOMr at baseline and after 12 months. Subjects whose ratio was >=1 were categorized as in positive BB, <1 categorized as in negative BB. General linear models were fitted to predict %chg BMD, with SG and BB category as fixed factors, and P1NP and CTX as covariates. Results: %chg total hip BMD was higher (p=0.027) in the 50g group compared to the control group. %chg total body BMD was higher (p=0.040), in the positive BB group at 12 months, compared to the negative BB group with no SG effects. SG (p=0.018), BB category at 12 months (p=0.002), and %chg P1NP (p=0.009) were significant predictors of %chg in hip BMD (R2=0.12), with negative effects of control group and negative BB. %chg CTX was a significant predictor of %chg in lumbar spine BMD (p=0.038), but no SG or BB category effects were observed. No effects of intervention group, BB category, or BTM were observed for %chg in femoral neck BMD. Conclusion: BB and %chg P1NP, along with prune intake, have significant effects on %chg hip BMD. BB is a useful indicator of 12-month %chg in hip BMD.

Centers for Medicare & Medicaid Services of USA issues reminders to use 25-OH Testing Wisely. *Ravinder Singh[1]. [1]Professor, United States

We will use 25-OH vitamin D Testing as a case example and educate the attendees about the impact of the changes in reimbursement on practice. The clinical use of the ordering of Vitamin D testing has become very controversial. It has been used as a general screening tool to use this test in only very serious diseases. CMS now restricts its use for only rare disease situations; The measurement of 25(OH) Vitamin D levels will only be considered medically reasonable and necessary for patients with any of the following conditions: Chronic kidney disease stage III or greater. Hypercalcemia, Hypocalcemia, Hyperparathyroidism, Hypoparathyroidism, Osteomalacia, Osteoporosis, Osteopenia, Rickets, Vitamin D deficiency to monitor the efficacy of replacement therapy, Malabsorption states, Cirrhosis (biliary, hepatic), Tuberculosis, Histoplasmosis, Coccidioidomycosis, Berylliosis, Follicular lymphoma, Immunodeficiency with predominantly antibody defects, Sarcoidosis, Hyperalimentation, Cystic fibrosis, Inflammatory Bowel Disease (Crohn's, Ulcerative Colitis), Radiation enteritis, Liver cirrhosis, Psoriasis, Systemic Lupus Erythematosus, Myositis , Obesity, Bariatric surgery, Long-term use of medications known to lower vitamin D levels. To receive payment documentation of this diagnosis is an essential requirement. 1,25 dihydroxy vitamin D has also been misordered and will not be anymore reimbursed by the CMS.

Vitamin D Metabolites are Associated with Overuse Musculoskeletal and Bone Stress Injury in Young Adults *Alexander Carswell[1], Thomas O'Leary[2], Paul Swinton[3], Sarah Jackson[2], Jonathan Tang[1], Samuel Oliver[4], Rachel Izard[5], Neil Walsh[6], William Fraser[1], Julie Greeves[2]. [1]University of East Anglia, United Kingdom. [2]Army Health and Performance Research, United Kingdom. [3]Robert Gordon University, United Kingdom. [4]Bangor University, United Kingdom. [5]Defence Science and Technology, United Kingdom. [6]Liverpool John Moores University, United Kingdom

The relationship between vitamin D metabolites and overuse injury is unclear. In a prospective cohort study, we investigated the association between vitamin D metabolites and incidence of lower body (pelvis and lower limb) overuse musculoskeletal and bone stress injury in young adults undergoing 12 weeks of initial military training during all seasons. In 1637 male and 530 female recruits (age, 22.6 +/- 7.5 years; BMI, 24.0 +/- 2.6 kg·m-2; 94.3% white ethnicity), we measured serum 25-hydroxyvitamin D (25(OH)D) and 24,25-dihydroxyvitamin D (24,25(OH)2D) by high-performance liquid chromatography tandem mass spectrometry, and 1,25-dihydroxyvitamin D (1,25(OH)2D) by immunoassay during week 1 of training. We used logistic regression to examine whether vitamin D metabolites were associated with overuse injury, including analysis of whether the relationship between 25(OH)D and 1,25(OH)2D:24,25(OH)2D ratio (with participants categorised into clusters) was associated with overuse injury. During training, 21.0% sustained >=1 overuse musculoskeletal injury, and 5.6% sustained >=1 bone stress injury. After controlling for sex, BMI, 2.4 km run time, smoking, bone injury history, and Army training course (Officer, standard, or Infantry), lower body overuse musculoskeletal injury incidence was higher for participants within the second lowest versus highest quartile of 24,25(OH)2D (OR: 1.62 [95%CI 1.13-2.32; P = 0.009]; 3.2-5.1 versus 7.7-29.6 nmol·L-1) and lowest versus highest cluster of 25(OH)D and 1,25(OH)2D:24,25(OH)2D (OR: 6.30 [95%CI 1.89-21.2; P = 0.003]; 6.9-38.5 nmol·L-1 and 125-307 versus 107.2-222.5 nmol·L-1 and 6-32). Lower body bone stress injury incidence was higher for participants within the lowest versus highest quartile of 24,25(OH)2D (OR: 4.02 [95%CI 1.82-8.87; P < 0.001]; 0.4-3.1 versus 7.7-29.6 nmol·L-1) and lowest versus highest cluster of 25(OH)D and 1,25(OH)2D:24,25(OH)2D (OR: 22.08 [95%CI 3.26-149.4; P = 0.001]), after controlling for the same covariates. Greater conversion of 25(OH)D to 24,25(OH)2D, relative to 1,25(OH)2D (i.e., low 1,25(OH)2D:24,25(OH)2D), and higher serum 24,25(OH)2D were associated with a lower incidence of lower body overuse musculoskeletal and bone stress injury. Serum 24,25(OH)2D may have a role in preventing overuse injury in young adults undertaking arduous physical training. Whether supplementation with vitamin D or its metabolites can decrease 1,25(OH)2D:24,25(OH)2D, and reduce the incidence of overuse injury is unknown.

Virtual Spatial Representation of scRNAseq Data Obtained from Human Articular Cartilage *David Rowe[1], Heather Swahn[2], Martin Lotz[3], Dong-Gulk Shin[4]. [1]University of Connecticut Health, United States. [2]Scripps Research, United States. [3]Scripps Institute, United States. [4]University of Connecticut, United States

Imaging the proliferation and maturation of different cell lineages within skeletal models of tissue formation and regeneration play an important role in understanding the cell and molecular mechanisms that control these biological processes. EdU and histone-marking strategies have provided valuable insights, but these technologies have limitations for in vivo marking and lineage tracing. The AurkbCreER mouse was originally developed by the D. Li laboratory (PMID: 32929201) for soft tissue imaging. We obtained this tamoxifen-activated mitosis reporter of the aurora kinase B (Aurkb) gene to evaluate its utility for models important to the skeletal biologist. Three different applications were evaluated. (1) Growth plate: Weaning mice were injected with tamoxifen a at 3-4 weeks of age and followed from 1 to 24 days while receiving a injection of calcein 1 day prior to sacrifice. This protocol labeled very few cells in the resting zone but did label occasion cells in the proliferative zone and many cells in the metaphyseal zone. No activity was observed in the articular cartilage nor in osteocytes under these labeling conditions. Concurrent stains for TRAP and AP distinguished the labeled cells as osteoclasts or osteoblasts. (2) Transplantation: BMSC progenitor cells were implanted in a calvarial defect model, and the recipient mice injected with tamoxifen 1 day after implantation. The implants were harvested at 7, 14 and 21 days post implant while receiving an injection of calcein 1 day prior to sacrifice. Imaging the implanted bone nodule that developed within the defect space clearly distinguished host and donor osteoblastic cells. (3) Cell culture: Mature transgenic mice were injected with tamoxifen 1 day prior to harvesting the bone marrow for osteoblast nodule and osteoclast culture. Time lapse video were recorded to capture the early formation of each cell type, while the transgene expression in a terminal osteoclast culture augmented the clarity of the cell border of the mature osteoclast. Although further characterization of this imaging model will be required, we envision that the reporter line will be valuable when combined with spatial techniques (CODEX and MERFISH) for identifying the precise cell identity of the cell expressing the progeny cell of a in both tissue section and primary cell culture systems.

Rare Coding Variant in SERT is Associated with Improved Bone Mass in Mice and Humans *Emily Larson[1], Hillary Larson[1], Eric Orwoll[2], Robert Klein[1]. [1]Veterans Affairs Portland Health Care System, United States. [2]Oregon Health & Science University, United States

Common susceptibility loci thus far identified by genome-wide association studies (GWAS) account for a small proportion of the estimated genetic heritability of bone mineral density (BMD). One explanation for the missing heritability is the existence of less common variants with larger biological effects that are poorly detected by GWAS. We hypothesized that genes contributing to biological pathways that regulate BMD could be identified by studying subjects at the phenotypic extremes for BMD. Subjects from the Osteoporotic Fractures in Men Study (MrOS) with the lowest total hip BMD (N =?98) and highest BMD (N =?110) were selected for exome sequencing. We observed an amino-terminal-localized Gly56Ala substitution (rs6355) in the serotonin transporter (SERT or SLC6A4) with a minor allele frequency 4-fold higher in the high BMD pool (4.1%) compared to the low BMD pool (1%). In the entire MrOS European-American population (n=5,008) associations between rs6355 and total hip BMD (maf 1.8%; ? = 0.31; p = 5x10-5) and femoral neck BMD (maf 1.8%, ?= 0.29; p = 1x10-4) were again confirmed. Inspection of the GEFOS Femoral Neck BMD 2012 Data Release provided concordant support for this variant (maf 2.4%; ? = 0.06; p = 0.014). To further explore this novel association, we examined SERT Ala56 mouse knock-in mice (provided by R. Blakely, Florida Atlantic University). Compared to wild-type Gly56Gly littermates, male SERT Ala56Ala knock-in mice demonstrated increased whole body (3.3%; p < 0.01) and femoral (3.3%; p < 0.01) BMD and greater resistance to 3-point bending (12%; p < 0.001). In contrast, no genotype-dependent effect on any skeletal parameter was observed in female SERT Ala56Ala knock-in mice. The rs6355 variant has been demonstrated to exhibit tonic elevation of serotonin (5-HT) transport activity in transfected cells and human lymphoblasts in vitro and when examined in a SERT Ala56 knock-in mouse model leads to an increased 5-HT clearance rate in vivo, along with altered sensitivity to SERT regulatory signaling pathways. The mechanisms whereby this variant results in the acquisition and/or maintenance of increased bone mass are unclear, but our results in both

mice and humans suggest that serotonin signaling is involved in skeletal physiology and manipulating this pathway is a potential target for the treatment of osteoporosis.

A comprehensive single cell transcriptomic atlas of adult human bone marrow *Michael Duffy[3], Shovik Bandyopadhyay[2], Kyung Jin Ahn[2], Kai Tan[2], Ling Qin[3]. [3]University of Pennsylvania, . [2]Children's Hospital of Philadelphia, United States. [3]University of Pennsylvania, United States

Bone marrow (BM) is primarily made of mesenchymal and hematopoietic lineage cells to provide mechanical support and produce blood. While mouse BM has been characterized at the single cell level, the rareness of mesenchymal cells in human BM aspirate has led to a lack of heterogeneity in scRNA-seq datasets and hindered human studies. Here, we developed a robust protocol to enzymatically isolate cells from fresh femoral head BM acquired after total hip arthroplasty. We separately enriched non-hematopoietic (CD45 depletion) and hematopoietic progenitor (CD34 selection) cells and then mixed them with RBC-depleted BM cells at 10:3:3 ratio for scRNA-seq using 10x genomics. From 12 samples (age 52-74, median 65+/-8), we profiled 53,417 hematopoietic and 29,325 non-hematopoietic cells at 3117 genes/cell and identified 35 cell clusters (Fig 1) of hematopoietic (25), mesenchymal (7), endothelial (2), and smooth muscle cells (1). Further analyzing 6 groups of mesenchymal cells, Fibro-mesenchymal stromal cells (MSCs), Osteofibro-MSCs, Osteo-MSCs, Osteoblasts, Adipo-MSCs, and THY1+ MSCs, with distinct markers, only Fibro-MSCs, marked by HAS1, DPT, and PDPN, expressed canonical mesenchymal stem markers and were identified as the most primitive population by CytoTRACE. Contributing a variable proportion of mesenchymal cells (52% +/- 31%, mean +/- SD), THY1+ and Adipo-MSCs highly expressed adipogenic markers. However, THY1+ MSCs had a unique expression profile including THY1 and LBP, and a high CytoTRACE score. We designed a flow panel to sort Fibro-, Thy1+-, Osteo-, and Adipo-MSCs. Fibro-MSCs showed the highest CFU-F forming ability and maintained the highest proliferative status over the long term culture, followed by THY1-MSCs, while Osteo- and Adipo-MSCs grew poorly. Fibro-MSCs also differentiated into osteogenic and adiopogenic cells efficiently in culture, confirming their stem and progenitor properties. CellChat analysis revealed that Adipo- and Thy1+-MSCs produce the highest amount of CXCL12 and KITL to regulate HSPCs and specifically express IL7 to regluate lymphopoiesis. Csf1, a major melopoiesis cytokine, was expressed in Adipo-MSCs, and Notch ligands, which are also important for lymphopoiesis, were mainly produced by arteriol endothelial cells. Together, our work presents a first comphrehensive cellular atlas of adult human bone marrow, identifies a new primitive MSC population, and reveals the importance of adipoprecursors in supporting hematopoeitic function.

Genetic Variants Associated with Lower Sclerostin Expression are Strongly Associated with Bone Physiology but not with Cardiovascular Events *James Staley[3], Gill Holdsworth[3], Jen Timoshanko[3], Alison Wolfreys[3], Cesar Libanati[3], Martin Armstrong[3]. [3]UCB Pharma, United Kingdom. [3]UCB Pharma, United States. [3]UCB Pharma, Belgium

Inhibition of sclerostin has been shown to increase bone formation and decrease bone resorption. Romosozumab (Romo), a sclerostin inhibitor, significantly increased bone mineral density and reduced fractures in postmenopausal osteoporosis (FRAME1 & ARCH2 trials). An increase in cardiovascular (CV) serious adverse events has been observed in Romo-treated patients compared to alendronate (ARCH).Genetic approaches such as phenome wide association studies and Mendelian Randomisation allow naturally occurring common genetic variation within a population to be used as a surrogate for the action of a drug, providing supporting data to predict both efficacy and on-target safety profiles. To explore the observations relating to Romo use, researchers have investigated genetic variants associated with lifelong reduced sclerostin expression and their associations with phenotypes, including those related to bone physiology and CV events and risk factors, in large-scale population datasets.In all analyses across research groups, genetically predicted lower sclerostin expression had strong positive effects on bone physiology, including lower lifetime risk of fractures and osteoporosis. There were, however, discrepancies in the results relating to CV events and risk factors between research groups. In our analyses3, we confirmed that variants associated with lower sclerostin expression were associated with phenotypes related to bone physiology but found no association with any phenotypes relating to CV events and risk factors. Other researchers have, however, published evidence linking genetically lower sclerostin expression with increased risk for some CV events, utilising similar data and statistical approaches.We reviewed the evidence and found that inappropriate adjustment for correlation between variants in some analyses (this issue was also raised by Holm et al.4) has led to inflated results of increased CV risk that have been overinterpreted. We also updated our genetic analyses using the latest data, including recently released sclerostin expression and CV event datasets, and the results broadly align with those we found previously. On balance, as a body of work, these investigations provide compelling evidence that genetically lower sclerostin expression is strongly associated with bone physiology, but not CV events.1Cosman NEJM 2016;375:1532-1543; 2Saag NEJM 2017;377:1417-1427; 3Holdsworth JBMR 2021;36:1326-1339; 4Hólm Sci Transl Med 2021;13:eabe8497

SUN-298

Large-Scale Integration of Human Bone Proteomics, Circulating Proteomics and Genetics to Discover Molecular Pathways and Risk Factors of Osteoporotic Fractures *Yi-Hsiang Hsu[1], Sjur Reppe[2], Fangtang Yu[3], Xue Zeng[4], Ming-Ju Tsai[3], Ronald Kwon[5], Kaare Gautvik[2]. [1]HSL Institute for Aging Research, Harvard Medical School, United States. [2]Oslo Univ. Hosp., Oslo, Norway, Norway. [3]HSL Marcus Institute for Aging Research , United States. [4]Amgen, United States. [5]University of Washington, United States

Despite significant progress being made in mapping the basic blueprints (DNA variants) of human diseases, we have yet to comprehensively decipher the myriad end products (proteins) contributing towards these diseases. Thus, proteomics is an emerging tool and a deeper view of proteome alterations in bone tissues from fractures will advance our understanding of molecular pathways and enhance new drug target discovery. In addition, identifying circulating protein biomarkers allows us to identify high risk subjects of fractures. Two proteomics studies were conducted. (1) Bone proteomics was measured by mass spectrometry on human hip bone biopsies from 180 hospitalized adults due to hip replacement surgeries. The whole genome seq was done and DXA FNBMD was measured at non-fracture hip. (2) Serum (circulating) proteomics was measured by OLINK immunoassays in 48,000 UK Biobank subjects. Incident osteoporotic fractures were assessed via eHR. Among them, 237 had osteoporotic fractures and 5,217 had DXA BMD. In both studies, differential protein expression analyses were performed w/wo adjusting for BMD to identify proteins contributing to fractures independently from BMD. Mendelian randomization (MR) analyses were performed to inference causally relations. We observed 6,154 proteins from hip bone biopsies. 198 (88 higher and 110 lower expressed) proteins significantly differentially expressed ($p < 1.7x10-5$) in fracture subjects comparing to controls. These proteins are enriched in terpenoids biosynthesis, ECM-receptors, cytokine-ligand-receptor interactions and TGF-beta, NFKB, PPAR signaling pathways. For example, SOST, VKDPs and EFEMP1 are associated with increased fracture risks. COL6A1, osteoadherin and osteopontin are associated with decreased risks. MR analyses adjusted for BMD identified proteins (e.g. CA2, EIF3I, EFEMP1) associated with fractures independently from BMD. For circulating proteomics, 2,941 proteins were measured. 81 (69 higher and 12 lower expressed) proteins significantly associated with incident osteoporotic fracture (e.g. SOST, GDF15, IL6). In conclusion, we identified novel proteins causally associated with osteoporotic fracture from hip bone biopsies. Not all the fracture-associated proteins observed in bone biopsies could be observed in circulating (plasma); thus, our finding provided tissue-specific molecular insights underlying osteoporotic fractures. We also identified novel circulating proteins predicating risks of incident fractures.

Exploration of Deep Learning for Automated Segmentation of the Trabecular Compartment of the Mouse Vertebral Body in Micro-Computed Tomography Images *Michael David[1], Veronica Butler[2], Douglas Adams[2]. [1]University of CO Anschutz, United States. [2]University of Colorado, United States

Automated micro-computed tomography (microCT) image segmentation of the trabecular compartment within the rodent vertebral body has been difficult to achieve. Despite a relatively high degree of success in automating this segmentation in long bones, the complexity in spinal anatomy and variation across rodent strains and between vertebral levels has slowed similar approaches for the spine. In this study, we developed a deep learning (DL) model with a U-Net framework to explore the utility of DL-based automation of this segmentation task. To maximize variation in vertebral anatomy for the DL model training

and eventual utility, we used 4th lumbar vertebra microCT images acquired from Diversity Outbred (DO) mice and the 8 founder inbred strains comprising the DO, as well as a subset of these mice following PTH treatment (N = 36, male & female). Following routine microCT scanning (70 kVp, 200 µA, 2000 projections,10 µm discretization), the transverse plane's desired trabecular compartment mask was selected via manual contouring. Each paired serial 2D mask and raw image (~170/vertebra) was imported into Python for DL model development. We used standard protocols for model development, including data scaling (min-max), 22/6/8 train/validate/test splitting, data augmentation (rotation and Gaussian blur), and evaluation metrics (dice score; 0 is poor segmentation, and 1 is perfect). Bone volume fraction and slice-by-slice Tb.Th and Tb.Ar were quantified using BoneJ (ImageJ). On the test set, our DL model accurately segmented the trabecular mask (dice score = 0.92), with resulting bone morphometry metrics being highly correlated (r >= 0.8) between DL and manual segmentation (Fig. 1A). Evaluating the model's performance slice-by-slice highlights the DL model's consistent ability to produce accurate segmentation (dice scores = ~0.88 - 0.95), while also revealing segmentation errors that may occur across a spectrum of anatomical variation (Fig. 1B and 1C). Qualitatively, the errors arise in regions with sparse trabecular architecture and within the posterior region when it resembles vertebral body anatomy (Fig. 1C), which might be eliminated by omitting this anatomical region from the DL model. DL model accuracy may also be improved by developing strain-specific models and increasing the training sample size. Ultimately, our DL model is a first step towards implementing automated high-throughput segmentation of the trabecular compartment of any mouse vertebral body.

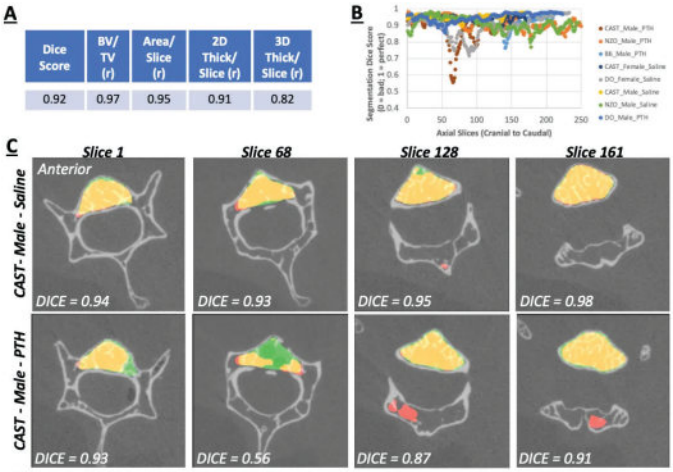

Figure 1. (A) DL model performs well on the test set (dice score ~1) with a high correlation coefficient (r) for bone morphometry between DL and manual segmentation. (B) Volume distribution of dice scores. (C) Slice-by-slice visualization from cranial (leftmost) to caudal (rightmost) of the averaged best (top row) and worst (bottom row) segmented vertebra; manual = green; DL = red; and union = yellow.

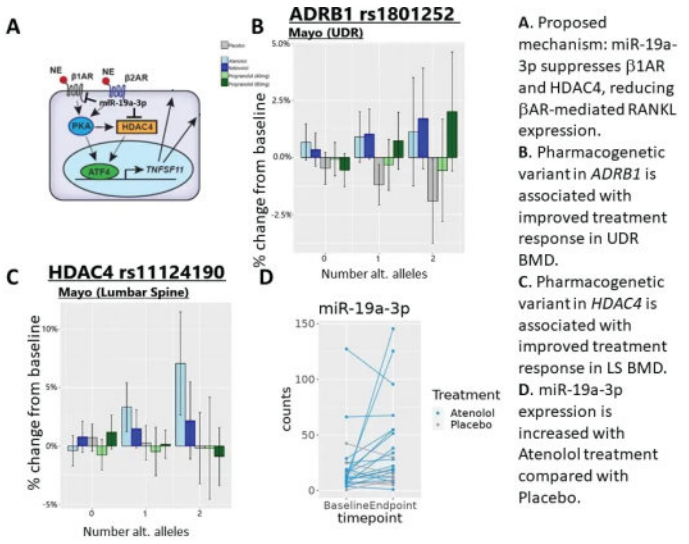
Pharmacogenetic and microRNA mechanisms of beta blocker treatment response in bone *Christine Lary[2], Griffin Scott[2], Hongyu Chen[2], Archana Nagarajan[3], Elizabeth Atkinson[4], David Monroe[5], Aaron Brown[6], Katherine Motyl[7], Sundeep Khosla[8], [2]Northeastern University, , [2]Northeastern University, United States, [3]Tufts University School of Biomedical Sciences, , [4]Mayo Clinic, United States, [5]Mayo Foundation, United States, [6]MaineHealth Institute for Research, United States, [7]MaineHealth, United States, [8]Mayo Clinic College of Medicine, United States

Atenolol, a beta-1 selective beta blocker (BB), is being evaluated to prevent postmenopausal bone loss in the randomized clinical trial, "Atenolol for the Prevention of Osteoporosis". Atenolol inhibits norepinephrine binding of the beta-1 and beta-2 adrenergic receptors (b1-AR and b2-AR) on osteoblasts and osteoclasts (Figure A). Previous pharmacogenetic effects have been found in b1-AR (ADRB1) and in HDAC4, a histone deacetylase that stabilizes ATF4-mediated upregulation of TNFSF11 (RANK Ligand) in osteoblasts. We have also shown that miR-19a-3p, which is associated with BB treatment response for hypertension, and which targets both b1-AR and HDAC4, is positively associated with BB use, bone mineral density (BMD), and reduced fracture risk. However, these associations have not been studied longitudinally with BB treatment. We analyzed pharmacogenetic data using variants from ADRB1, ADRB2, and HDAC4 in a pilot clinical trial performed at the Mayo Clinic in 155 postmenopausal women randomized to placebo, propranolol (40 mg or 80 mg), atenolol (50 mg), or nebivolol (5 mg) daily for 20 weeks. We also collected miRNA-seq data at baseline and endpoint from 24 participants, 9 each from the atenolol group with high response (HR) or low response (LR) based on changes in C-terminal telopeptide (CTX), and 6 from the placebo group. We modeled the change in BMD at the femoral neck (FN), lumbar spine (LS), or ultradistal radius (UDR) or in serum CTX as a function of baseline values, SNP dosage, treatment group, and their interaction. Longitudinal miRNA-seq data was analyzed using negative binomial regression with generalized linear mixed models. An increase in UDR BMD for the propranolol 80 mg group was found compared to placebo for each additional copy of the ADRB1 rs1801252 G allele (Figure B), and an increase in LS BMD and decrease in CTX was found for the atenolol group for each additional copy of the HDAC4 rs11124190 G allele (LS BMD in Figure C). miR-19a-3p was associated with a significant increase in the low responder group over time compared with placebo (OR = 2.8, p= 0.028) and with a trend towards significance in the combined atenolol groups (OR = 2.2, p=0.06, Figure D). Taken together these results are consistent with a mechanism in which genetic variation or miR-19a-3p-induced suppression of b1-AR and HDAC4 is associated with improved treatment response. These results will be validated in an ongoing ancillary study for the APO clinical trial.



A. Proposed mechanism: miR-19a-3p suppresses β1AR and HDAC4, reducing βAR-mediated RANKL expression.
B. Pharmacogenetic variant in *ADRB1* is associated with improved treatment response in UDR BMD.
C. Pharmacogenetic variant in *HDAC4* is associated with improved treatment response in LS BMD.
D. miR-19a-3p expression is increased with Atenolol treatment compared with Placebo.

Novel Genes and Transcription Factors Related to Skeletal Abnormalities in Down Syndrome *JARED THOMAS[1], Randall Roper[2], [1], [2]Indiana University-Purdue University Indianapolis, United States

Triplication of human chromosome 21 (Hsa21) results in Down syndrome (DS) and dysregulates neurological, cardiovascular, and skeletal development. Increased gene dosage may alter expression of both two- and three-copy genes leading to DS phenotypes. All individuals with DS present with low BMD and have an increased risk for early-onset osteoporosis and fragility fractures. Genetic determinants related to skeletal abnormalities in DS remain poorly understood. Ts65Dn DS model mice are trisomic for ~100 Hsa21 orthologous genes on mouse chromosome 16 (Mmu16) and ~35 Mmu17 non-Hsa21 orthologous genes, and recapitulate skeletal deficiencies observed in humans with DS. At six weeks both male and female Ts65Dn mice showed significantly reduced BMD and impaired trabecular and cortical architecture. Osteocytes regulate bone homeostasis and may contribute to skeletal abnormalities seen in DS. We hypothesized that trisomy alters gene expression genome wide in Ts65Dn mice in the developing skeleton affecting osteoblasts and osteocytes. To test this hypothesis, we performed RNA-Seq on femoral diaphyseal bone from six-week male and female euploid and Ts65Dn mice. Female trisomic compared to euploid mice had 1598 differentially expressed genes (DEGs) (upregulated = 672; downregulated = 926); male trisomic compared to euploid mice had 95 DEGs (upregulated = 93 and downregulated = 2). Female mice showed genome-wide altered expression, in contrast to male mice with the majority of DEGs located on Mmu16 (61%) and Mmu17 (17%). Female trisomic DEGs were identified in pathways related to cell cycle control, mismatch repair and cell cycle checkpoint control. Male trisomic DEGs included those in interferon and PI3K/Akt signaling; both play critical roles in skeletal development and bone formation. Both male and female mice had increased expression of Madcam1 (unknown bone function) and Stfa1 (role in osteogenic differentiation) that may be novel genes related to DS skeletal abnormalities. DEGs found in Ts65Dn mice may derail bone remodeling by impacting bone formation resulting in decreased BMD and weaker bones. Female as compared to male Ts65Dn mice at six-weeks of age display less severe skeletal deficits possibly due to upregulated DEGs that positively affect bone formation. This work identified new candidate genes and pathways involved in altered skeletal development that may provide new potential therapeutic targets for sex-specific treatments for individuals with DS.

Augmentation of BMP signaling leads to ectopic cartilages through changes in chromatin structures *YUJI MISHINA[1,] Hiroki Ueharu[1.] [1]University of Michigan,

Dysregulation of proliferation, migration, and differentiation of cranial neural crest cells (NCCs) develop craniofacial anomalies. We have reported that enhanced BMP signaling in NCCs (caAcvr1; P0-Cre mice, mutant mice hereafter) developed ectopic cartilages in the midfacial region at embryonic day 14.5 (E14.5). Pharmacologic rescue experiments using an inhibitor for BMP signaling revealed that a time window for suppression of ectopic cartilage formation is at E11.5, which is a stage before the initiation of the ectopic cartilage formation. We hypothesize that augmentation of BMP signaling directs the multipotency of cranial NCCs towards chondrogenesis. This study aims to reveal the mechanism for cell fate specification of cranial NCCs by BMP signaling. We compared gene expression profiles in cranial NCCs between control and mutant mice at E10.5 by single cell RNA sequence. In the mutant embryos, cranial NCCs formed the ectopic cartilages, but trunk NCCs did not, thus we speculated that genes changed only in cranial NCCs of mutant mice but not in trunk NCCs involve in the formation of ectopic cartilage. Through these 2 way comparisons, we identified 11 genes of which expressions are specifically changed in mutant cranial NCCs. Among these genes, we found that Xist, a main player for X chromosome inactivation, is significantly increased in cranial NCCs of mutant mice. We further observed that cranial NCCs in mutant female embryos have ectopic X chromosome inactivation: one cell has two inactive X chromosomes that are entirely coated with Xist RNA. Surprisingly, ectopic X chromosome inactivation was also found in cranial NCCs of mutant male mice, which should not have X chromosome inactivation. This finding may explain the fact that both male and female mutant mice develop ectopic cartilage in a comparable manner. We demonstrated that silencing of Xist in cranial NCCs decreases chondrogenic differentiation capacity in vitro, and genetic reduction of Xist in mutant mice by deletion of Kdm5C, a known factor positively regulates Xist expression, significantly reduced formation of ectopic cartilages. These results suggested that enhanced BMP signaling develops the ectopic cartilages through induction of ectopic X chromosome inactivation. This is for the first time to demonstrate BMP-Xist axis contributes cell fate specification of cranial NCCs in both sexes.

Does Slc20a2 Deficiency Alter Osteogenic Pathways? *Philip Walczak[1,] Marta Scatena[2,] Cecilia Giachelli[2.] [1]Department of Oral Health Sciences, University of Washington, United States[.] [2]Department of Bioengineering, University of Washington, United States

Background: Slc20a2 encodes the sodium dependent phosphate transporter PiT-2, one of two predominant phosphate transporters in hard tissues. Our lab previously showed that loss of Slc20a2 leads to impaired osteogenesis with shortened bones and decreased bone mineral density concomitant with decreased osteoblast numbers and function. Purpose: We hypothesize that decreased osteoblast numbers and impaired osteogenesis in Slc20a2 -/- mice results from downregulation of key osteogenic signaling pathways. Herein we demonstrate the application of spatial transcriptomic analysis to investigate gene expression in mouse tibias, and its potential alteration by loss of Slc20a2. Methods: C57Bl/6NTac-Slc20a2/Ieg (Slc20a2) mice were used to generate Slc20a2 WT and KO littermates under University of Washington IACUC #201600170. P24 left tibias were collected, formalin fixed, and demineralized. µCT scans of right calcified tibias were obtained to confirm phenotype. Demineralized samples were paraffin embedded and sectioned at 5?m. These slides were used for spatial transcriptomic analysis utilizing the NanoString GeoMX Digital Spatial Profiler (NanoString, Seattle, WA). Regions of interest (ROIs) were selected based on morphology, nuclear staining, and validated using marker genes, specifically proliferative zone, hypertrophic zone, primary spongiosa, and mature cortical bone. Results: µCT scans confirmed decreased bone density, decreased trabecular thickness, and decreased bone volume in P24 Slc20a2 KO compared to WT mice, consistent with previous findings in 10-week-old mice. Spatial transcriptomics allowed interrogation of morphologically distinct ROIs to validate predominant cell types. Genes with consistent differential expression in validated tissues were further investigated. Prickle1, a negative regulator of the canonical Wnt/?-Catenin pathway, was downregulated in Slc20a2 KO compared to WT. Conclusions: P24 Slc20a2 KO mice exhibit impaired osteogenesis compared to their littermates. Spatial transcriptomics enabled in situ whole-transcriptome analysis of Slc20a2 mutant mice to investigate the role of Slc20a2 in osteogenic pathways. Loss of Prickle1 has previously been shown by other groups to lead to shortened appendages and delayed osteoblast differentiation and migration, phenotypic findings observed in Slc20a2 KO mice. These results suggests that Slc20a2 may play a role in Wnt/?-catenin signaling, with deficiencies impairing osteogenesis.

Osteoporosis-Associated Genes Identified from Transcriptional Profile Reconstruction in Human Peripheral Blood Bulk RNA Sequencing *YUN GONG[2,] XIAO ZHANG[2,] CHUAN QIU[3,] Kuan-Jui Su[2,] Zhe Luo[2,] Qing Tian[2,] Hui Shen[2,] Hong-Wen Deng[2.] [2]Tulane University, United States[,] [2]Tulane University, [,] [3], United States

Bulk RNA sequencing (seq) provides an average gene expression profile for a population of cells. Despite of the cell isolation method has been used (positive or negative), a major limitation of bulk RNA-seq is it fails to identify and characterize cell composition and mask potential cellular heterogeneity in the cell population due to individual complexity of each cell. Therefore, it is essential to determine cell-type specific RNA-seq after cell-type adjustment in bulk RNA-seq data. Here, we performed a comparative analysis between adjusted versus unadjusted cell-type (i.e., classical monocytes) specific bulk RNA-seq data derived from peripheral blood monocytes obtained from 944 independent subjects and investigate their significant gene differences on osteoporosis risk in men. We used Bayesian cell proportion reconstruction inferred using statistical marginalization (BayesPrism) to uncover the cell composition in our bulk RNA-seq data and reconstruct the monocyte-specific transcriptional profile. Next, we will perform the Weighted Gene Co-expression Network Analysis (WGCNA) to identify highly co-expressed clusters of genes associated with bone mineral density (BMD) using unadjusted and adjusted RNA-seq data. Through this comparative analysis, we expect to identify significant and novel BMD-associated genes and networks which could not be identified in the unadjusted bulk RNA-seq.

Identification of genetic risk factors for hip osteoarthritis acting through altered hip shape: findings from a genome-wide association meta-analysis of 43,485 individuals *Benjamin Faber[1,] Monika Frysz[1,] Jiayi Zheng[2,] Huandong Lin[3,] Raja Ebsim[7,] Fiona Saunders[5,] Jenny Gregory[5,] Richard Aspden[5,] Nicholas Harvey[6,] Claudia Lindner[7,] Tim Cootes[7,] Sijia Wang[8,] John Kemp[9,] Jonathan Tobias[1.] [1]University of Bristol, United Kingdom[.] [2]3) CAS Key Laboratory of Computational Biology, Shanghai Institute of Nutrition and Health, University of Chinese Academy of Sciences, Chinese Academy of Sciences, Shanghai, China, China[.] [3]Department of Endocrinology and Metabolism, Zhongshan Hospital, Fudan University, Shanghai, China., China[.] [7]Division of Informatics, Imaging and Data Science, University of Manchester, UK, China[.] [5]Centre for Arthritis and Musculoskeletal Health, University of Aberdeen, UK, United Kingdom[.] [6]University of Southampton, [.] [7]Division of Informatics, Imaging and Data Science, University of Manchester, UK, United Kingdom[.] [8]3) CAS Key Laboratory of Computational Biology, Shanghai Institute of Nutrition and Health, University of Chinese Academy of Sciences, Chinese Academy of Sciences, Shanghai, China., China[.] [9]The University of Queensland, Australia

PurposeHip shape is an important risk factor for hip osteoarthritis (HOA) that is heritable. In this study we aimed to identify new genetic determinants of hip shape, and assess their relationship with HOA.MethodsStatistical hip shape modelling was used to derive 10 orthogonal hip shape modes (HSMs) from DXA images in two cohorts. These include 38,175 UK-Biobank Study participants, as well as 5,310 participants from the Shanghai Changfeng Study. Genome-wide association studies (GWAS) were conducted on the HSMs and resulting summary statistics were meta-analysed using an inverse variance weighted fixed effects method. Statistically independent HSM-associated single nucleotide polymorphisms (SNPs) were identified using GCTA-COJO. HSM-associated SNPs were looked up in a recent GWAS of HOA and pleiotropy was assessed using a Bonferroni corrected p-value threshold of P<1.6x10-4. Statistical fine mapping was used to highlight genes that may be functionally related to hip shape.ResultsAnalysis of the first 10 HSMs identified 308 statistically independent association signals in total (P<5x10-8). These included SNPs that mapped to 8 known HSM-associated loci, as well as a further 261 that mapped to novel loci. SNPs in 17 loci were also associated with HOA. Fine mapping implicated SMAD3 and PLEC as candidate genes that may be involved in the development of hip shape as well as HOA. Rs12901499 intersected SMAD3 and was associated with increased medial femoral head displacement (HSM4: ?=0.05, P=1.7x10-13, Figure 1) and a lower risk of HOA (?=-0.07, P=2.8x10-15). It also colocalized with SMAD3 mRNA expression in cartilage [posterior probability (PP) 98%]. Moreover, rs12541377 intersected PLEC and it was associated with a narrower femoral neck (HSM7: ?=0.05, P=2.55x10-11, Figure 1), and lower HOA risk (?=-0.04, P=2.6x10-6). It also colocalized with PLEC mRNA expression in synovial tissue (PP 96%).ConclusionsWe report the largest hip shape GWAS meta-analysis to date that identifies hundreds of novel loci, many of which are also associated with HOA. Fine mapping highlighted SMAD and PLEC in the development of hip shape and HOA. Both genes warrant further investigation as they could represent potential therapeutic targets for HOA.Figure 1 Legend. SUN-306

Differential transcriptional responses to intracellular infection by S. aureus in osteoclasts and their precursors. *Luke O'Connor[1], Deborah Veis[2,1], [2]Washington University in St. Louis School of Medicine, United States

S. aureus is an opportunistic pathogen that causes 30-50% of all osteomyelitis (OM) cases. During OM, S. aureus survive in colonies, as well as within osteocytes, osteoblasts, and osteoclasts (OCs). We have recently shown that OCs, unlike their bone marrow macrophage (BMM) precursors, allow bacteria to replicate intracellularly and the magnitude of growth increases with OC differentiation . We hypothesized that OC differentiation alters host-pathogen interactions by changing nutrient availability and host defense pathways to favor intracellular S. aureus growth. To test this, we conducted dual RNA-seq to analyze host and S. aureus gene expression at 4 critical infection timepoints: prior to infection, after bacterial internalization (2h), during bacterial metabolic transition (6h), and after bacterial expansion in OCs or killing in BMMs (21h). Bone marrow was cultured from 6-7 week-old male B6/alb mice, and BMMs (MCSF only) or OCs (3 days RANKL) generated prior to infection with USA300 MRSA strain TI3. To ensure data robustness we sequenced 3 batches of pooled samples per cell type, with each pool representing 3 mice and 3 separate infections (total: 18 mice, 10 infections). S. aureus transcripts were aligned to S. aureus USA300_FPR3757 and DESeq2 used to analyze genes differentially expressed by cell type (BMM vs OC) over the time course. In parallel, we used PyModulon to analyze modules of co-regulated genes in bacteria. These analyses show that bacteria in OCs have lower expression of Fur regulated iron scavenging genes as well as genes related to CodY, PerR, PurR, and CymR, which regulate amino acid metabolism. Thus, S. aureus in OCs may be less stressed for iron and amino acids than bacteria in BMMs. Murine host transcripts were aligned to Mm39 and analyzed in DESeq2, followed by supplemental analysis with Gene Ontology (GO) enrichment and using weighted coregulated gene network analysis (WGCNA). GO analysis highlights that OC and BMM responses largely differ in host defense and bacterial response pathways. WGCA of all differentially expressed genes and a subset of genes from the top 10 GO identify Pi3kr1, Id2, and ZO-2 as genes highly interconnected with differential host response and indicate a potential roles for PI3K, TGF-?, and Hippo signaling pathways. Collectively these results suggest OCs have an altered response to infection and provide greater access to nutrients than their BMM precursors, allowing S. aureus expansion in OCs but not BMMs.

Subchondral bone migration into trabecular bone in response to direct bone-on-bone contact wear in patients with severe knee osteoarthritis *Meret Keiser[1], Stefan Preiss[2], Stephen J Ferguson[3], Vincent A. Stadelmann[1]. [1]Department of Research and Development, Schulthess Klinik, Switzerland. [2]Department of Knee Surgery, Schulthess Klinik, Switzerland. [3]Institute for Biomechanics, ETHZ, Switzerland

INTRODUCTION: Although it is well established that osteoarthritis (OA) is accompanied by changes in subchondral bone microstructure, such as cortical thickening, little is known about microstructural adaptations at and around full-thickness cartilage defects in severe knee OA. This high-resolution microCT study therefore aimed to describe and quantify subchondral bone changes due to wear under direct bone-on-bone contact in patients with severe OA.METHODS: Ten tibial plateaus showing full-thickness cartilage defects were retrieved from total knee arthroplasty patients. All patients provided signed informed consent. Six 5x5 mm specimens were cut with a diamond saw from the defect, defect-edge, and cartilage region and two from the contralateral side. These were microCT-scanned at a resolution of 3.3 µm. Bone volume fraction (BV/TV) and Tissue Mineral Density (TMD) were analysed layer-by-layer to compute the specimens' density profiles and identify cortical and trabecular bone regions. Bone formation around cortical porosity was derived from the gradient of mineral density around the pores.RESULTS: The subchondral bone plate below full-thickness cartilage defects appears to migrate into trabecular bone through direct thickening and through pockets of bone formation within the trabecular structures. In cases with deep wear grooves, trabecular pores occasionally connect with the joint space before they are completely filled with new bone. The spatial expansion of these effects shows a sharp boundary at the defect-edge, almost immediately disappearing under regions covered with even a minimal layer of cartilage (Fig. 1). Quantitatively, cortical bone was 4-fold thicker below defects than below cartilage. BV/TV and TMD profiles significantly differed between defect, edge, and cartilage specimens, up to 5mm deep. Below defects, cortical porosity and trabecular BV/TV were 85% and 14% higher and TMD 6% lower compared to cartilage specimens. The TMD gradient around pores was greatest in the edge specimens. DISCUSSION & CONCLUSIONS: This is the first study to bring new insights into bone microstructural adaptations below full-thickness cartilage defects in severe knee OA. We observed subchondral plate migration below cartilage defects via trabecular osteogenesis. Our data shows an increased bone formation in defect and edge regions, reflecting the wear of native cortical bone and trabecular corticalisation, causing the cortical layer to migrate down into the trabecular bone.

SUN-308

State-level impact of arthritis pain on patients using a patient-oriented outcomes survey *SIERRA STREET[1], Jonathan Lowery[2,1], [2]Marian University, United States

Arthritis is a group of over 100 joint conditions and diseases that affects more than 54 million adults in the US and places an enormous burden on the US. healthcare system. Despite this, there is a poor understanding of the real-life experiences and daily challenges faced by patients with arthritis. Hence, in collaboration with the Arthritis Foundation, we took a patient-oriented outcomes approach to determine the impact of arthritis on patients through an electronic survey developed with input from patients, healthcare providers, and measurement experts and includes measures from validated questionnaires to allow allowing for comparison to established benchmarks of the general population. Nationwide, the survey has received over 40,000 responses. However, aggregate nature does not allow for examining region-specific differences, which potentially limits the project's ability to influence advocacy efforts at the local, state, healthcare system and/or regional levels. Thus, we initiated a state-focused project to better understand the impact of arthritis on Indiana residents. Among the 515 responses from Indiana, most respondents have osteoarthritis (43%) along with a variety of other forms of arthritis including Rheumatoid Arthritis (32%). Most respondents from Indiana, hereafter referred to as "Hoosiers," are female (79%) and identify as "white" (82. 100% of respondents reported pain in the week prior to taking the survey with an average pain score of 4.92. 29.2% of survey participants indicated a high or moderate pain score, while 58.3% of participants indicated a low pain score.. 62% of Hoosier patients with a higher pain score - i.e., 7 or higher out of 10 -report difficulty with doing all of their regular leisure activities with others compared to 7% of patients with a low pain score of 4 or below. 66% of Hoosier patients report difficulty of all activities with friends that they would like to do compared to 13% of patients with a low pain score. 85% of Hoosier patients with a high pain score report their pain interferes with their day-to-day activities compared to 6.5% of patients with a low pain score. In addition, 75% of Hoosier patients with a high pain score report their pain interferes with their ability to participate in social activities compared to 6% of patients with a low pain score. 50% of patients with a high pain scale reported they felt their choices were respected compared to 82% of patients with a low pain scale. 45% of patients with a high pain scale reported they were able to speak with a professional to get their questions answered compared to the 75% of patients with low pain. Our results indicate that debilitating pain is a major challenge for patients and it is associated with negative impacts on lifestyle and emotional/social health. Future work seek to increase the representation of additional race or ethnics groups, men, and patients with additional forms of arthritis.

The Effect of Antiresorptive Agents on Periprosthetic Bone Mineral Density After Non-Cemented Hip Arthroplasty: A Literature Review and Meta-Analysis of Randomized Controlled Trials. *José Francisco Torres-Naranjo[1], Roberto E López Cervantes[2], Roberto Gabriel Gonzalez Mendoza[3], Hugo Gutierrez Hermosillo[4], Darío Esaú Garin Zertuche[5], Luis A Padilla Rojas[6], Pedro Alberto García Hernandéz[7]. [1]Centro de Investigación Ósea, CIO; Asociación Mexicana de Metabolismo Óseo y Mineral , AMMOM, Mexico. [2]CFO, Federación Mexicana de Colegios de Ortopedia y Traumatología, FEMECOT , Mexico. [3]Instituto de Ciencias Aplicadas a la Actividad Física y el Deporte, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara., Guadalajara, Mexico, Mexico. [4]Asociación Mexicana de Metabolismo Óseo y Mineral, AMMOM, Mexico. [5]Federación Mexicana de Colegios de Ortopedia y Traumatología FEMECOT, Mexico. [6]Federación Mexicana de Colegios de Ortopedia y Traumatología, FEMECOT, Mexico. [7]Facultad de Medicina, UANL, Monterrey, Mexico

Arthroplasty is a common surgical procedure for patients with joint diseases, and its frequency continues to increase. However, its impact on peri-prosthetic bone mass and clinical outcomes is poorly understood. Additionally, the efficacy of osteoporosis medications in managing peri-prosthetic bone loss is uncertain.PurposeThis study aimed to evaluate the effect of antiresorptive agents on periprosthetic bone mineral density after non-cemented hip arthroplasty.MethodsWe conducted a comprehensive search of databases such as "PubMed," "Scopus," "Web of Science," and "ScienceDirect" in August 2022. An additional search was conducted to detect possible related studies not found in the classic search using review and meta-analysis. We included studies that had at least two periprosthetic bone mineral density measurements. When authors did not report numeric bone mineral density, data were iterated from graphs. The primary outcome of interest was the periprosthetic bone mineral density change over time. Given the lack of control or description of various factors in most studies, a random-effects meta-analysis was performed using the "DerSimonian and Laird" approach.ResultsWe conducted a random-effects meta-analysis of 29 studies comprising 1182 adult patients. Six hundred fourteen of whom underwent elective total non-cemented hip arthroplasty surgery and received antiresorptive treatment after the procedure, and 568 controls. Our meta-analysis showed that after hip arthroplasty, there is a significant decrease in bone mineral density (BMD) in the periprosthetic bone. Antiresorptive treatments consistently preserve periprosthetic bone mineral density in Gruen Zone 1 during the 24 months after surgery. In Zone 7, we observed a similar effect only during the first 18 months after surgery. Although not the study's primary objective, we also observed this effect is maintained for up to 60 months.During the literature review, we noted significant variations in the techniques used to acquire and analyze periprosthetic DXA scans.ConclusionsOur findings suggest that after non-cemented hip arthroplasty, there is a significant decrease in BMD in the periprosthetic bone during the first 24 months after surgery. However, the use of antiresorptive agents appears to attenuate this loss. It is important to note that several studies lack adequate information about baseline BMD or other critical factors, highlighting the need for further research to fully understand the effects of surgery on bone health.

SENP6 mediated desumoylation regulates osteoarthritis development *Tao Yang[1]. [1]Van Andel Institute, United States

SUMOylation is a reversible posttranslational modification that broadly controls protein-protein interaction, stability, and activity, and plays essential roles in regulating genomic stability, epigenetic states, and stress responses. A genome-wide association study (GWAS) published by the arcOGEN Consortium showed a strong association between human osteoarthritis (OA) and the single nucleotide polymorphisms (SNPs) of the small ubiquitin-like modifier (SUMO) specific peptidase 6 (SENP6), which removes SUMO modifications from specific protein targets. A follow-up study further demonstrated that SENP6 expression decreases in OA hip cartilage relative to non-OA controls. These implicate that SENP6-mediated de-SUMOylation is critical for OA development and that altered SENP6 function could be a target of intervention for treatment of human OA. Here, we found that chondrocyte-specific loss of SENP6 promotes articular chondrocyte (AC) senescence and inflammation and accelerates the onset and progression of post-traumatic OA (PTOA) and age-related OA. Furthermore, loss of SENP6 increases AC senescence and contributes to an abnormal stress response, and an altered epigenetic landscape. Finally, mice with chondrocyte-specific gain of SENP6 expression showed delayed onset and progression of PTOA. Our work overall demonstrated that SENP6-mediated de-SUMOylation contributes to articular cartilage homeostasis, and that increasing the expression level or activity of SENP6 may be used therapeutically to slow down/prevent joint degeneration.

Risk Factors for Skeletal Complications Following Spine Fusion Surgery in Postmenopausal Women *Alexander Dash[1], Emma Billings[2], Han Jo Kim[3], Matthew Cunningham[3], Darren Lebl[3], Francis Lovecchio[3], John Carrino[3], Joseph Raphael[3], Katelyn Vlasartis[4], Donald McMahon[5], Emily Stein[3]. [1]Icahn School of Medicine at Mount Sinai, . [2]Hospital for Special Surgery , . [3]Hospital for Special Surgery, United States. [4]Case Western Reserve University, United States. [5]Columbia University College of Physicians and Surgeons,

Spine fusion surgery is one of the most common orthopedic procedures, with close to 500,000 performed annually in the Unites States alone. Early stability of surgical hardware in bone and de novo bone formation are critical for fusion success. Complications occur in up to one-third of cases, and are more common in patients with underlying skeletal deficits. The FUsion and Skeletal Evaluation in patients unDergoing SPINE surgery (FUSED SPINE) ongoing prospective cohort study of adult men and women investigates the relationship between pre-operative bone quality and post-operative outcomes. Here we present data on a sub-group of postmenopausal women, a group that may be at particular risk for skeletal complications due to the effects of aging and estrogen deficiency. We hypothesized that women with abnormalities in volumetric BMD (vBMD) and microarchitecture would have higher rates of post-operative complications. Pre-operative assessments included areal BMD (aBMD) of the spine, hip, and forearm by DXA, cortical and trabecular vBMD and microarchitecture at the radius and tibia by high resolution peripheral quantitative CT (HRpQCT; Xtreme CT2). Cox Proportional Hazard Models that included clinical characteristics (age, BMI, smoking, alcohol, number of vertebrae included in surgery) and HRpQCT measures were utilized to identify the best predictors of post-operative skeletal complications. Among 50 women enrolled (mean age 65), pre-operative aBMD at the spine was normal; fewer than one-third had DXA measurements in the osteoporotic range at any site. Number of vertebrae included in surgery ranged from 2 to 17; 52% of cases included >=6 levels. Median post-operative follow-up was 15 months. Skeletal complications occurred in 46% of women. In Cox models, earlier time to complication was related to greater number of surgical levels (HR 1.19 95% CI 1.06-1.34), lower tibia total area (HR 0.60 95% CI 0.41-0.86) and lower tibial cortical thickness (HR 0.74 95% CI 0.57-0.95; model p <0.01, Figure). In summary, postmenopausal women with smaller bones, thinner cortices and those having procedures involving a greater number of vertebrae were at highest risk for post-operative complications. Our results highlight the risk of skeletal complications among postmenopausal women who undergo complex multi-level procedures, despite normal appearing DXA. They further illustrate the influence of bone size and cortical integrity on post-operative outcomes in this population.

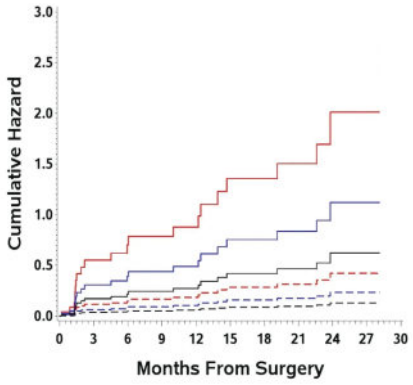

Figure: Lower cortical thickness and greater number of fusion levels associated with increased hazard of post-operative complications. Cumulative hazard shown by tertiles of tibial cortical thickness. Green lines represent lowest tertile (0.6 to <1.2 mm), blue lines represent middle tertile (1.2 to <1.7 mm), red lines represent highest tertile (>=1.7 mm). Dashed lines < 6 surgical levels and solid lines ≥ 6 surgical levels.

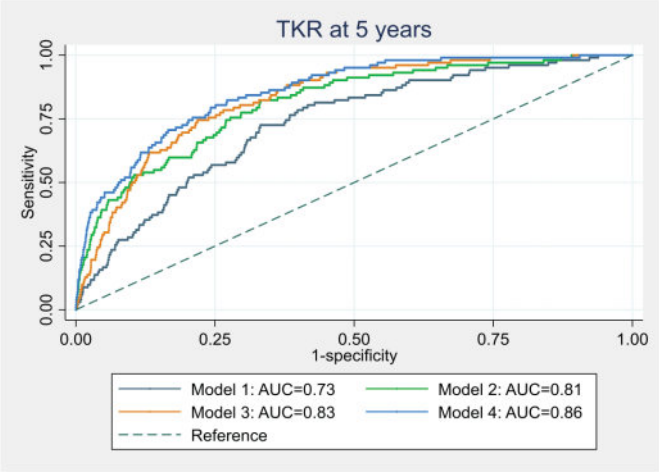
DXA-derived knee shape may provide a useful imaging biomarker for predicting total knee replacement: findings from UK Biobank *Rhona Beynon[1], Fiona Saunders[2], Raja Ebsim[3], Monika Frysz[1], Ben Faber[1], Jenny Gregory[2], Claudia Lindner[3], Richard Aspden[2], Nicholas Harvey[4], Tim Cootes[3], Jon Tobias[1]. [1]University of Bristol, United Kingdom. [2]University of Aberdeen, United Kingdom. [3]University of Manchester, United Kingdom. [4]University of Southampton, United Kingdom

Purpose: Advanced knee osteoarthritis (kOA) is commonly treated with total knee replacement (TKR). We aimed to develop an imaging biomarker for predicting TKR, using knee dual-energy X-ray absorptiometry (DXA) scans obtained from the UK Biobank study. Methods: We used statistical shape modelling (SSM) to generate orthogonal knee shape modes (kSMs) from DXA images of the left knee, excluding osteophytes. A B-score was generated for each individual (n=37,844) by projecting the kSMs along a vector representing the difference between the mean knee joint shape of healthy individuals and those who had undergone TKR. A custom script automatically measured the minimum joint space width (mJSW), which was then binarised for analysis based on whether the medial compartment mJSW fell within the first quartile. For a subset of individuals, osteophytes were manually

graded on a 0-3 scale and an aggregate grade was generated for each knee. Cox proportional hazards models were used to evaluate the relationship between DXA-derived measures and TKR incidence in this sub-sample. We evaluated the predictive ability of DXA-derived variables both independently and in combination with demographic characteristics (age, sex, height, and weight) using Harrell's concordance index (C-index). To assess the accuracy of predicting TKR incidence at five years, we computed the area under the receiver operating characteristic curve (AUC).Results: Full data were available for 6,719 individuals (mean age: 63 years [SD 7.5]; 49% males). B-score, mJSW and osteophyte grade were independently associated with TKR, with hazard ratios (HRs) of 2.63 (2.22,3.11; p<0.001), 2.97 (CI=2.04,4.33; p<0.001), and 8.40 (5.44,12.96; p<0.001), respectively. Corresponding C-statistics were 0.75, 0.63 and 0.75. The model comprising B-score, composite osteophyte grade and demographic variables yielded the best fit and discrimination (C-statistic=0.86). This model showed good discrimination in predicting TKR at 5-years, with an AUC of 0.86, compared to a model with only demographic variables, which had an AUC of 0.73 (Figure 1).Conclusions: An imaging biomarker combining B score (reflecting knee shape) and osteophytes substantially improved prediction of TKR compared with demographic factors alone. These results suggest that DXA-derived imaging biomarkers could prove useful in identifying those at high risk of kOA progression, in whom the focus should be on interventions to slow this process.

Figure 1: Receiver Operating Characteristic (ROC) Curve for Prediction of Knee Replacement at 5 Years (n=6,719).



Model 1: age, sex, height, and weight; Model 2: age, sex, height, weight, B-score; Model 3: age, sex, height, weight, composite osteophyte grade; Model 4: age, sex, height, weight, B-score, composite osteophyte grade.

Single-cell RNA Sequencing of Human Bone Marrow Mesenchymal Stem Cells Reveals the Cellular Interactions in Osteonecrosis of the Femoral Head *Tian-Ying Li[1], Jia-Qi Wang[1], Xiao-Hua Li[2], Junxiao Yang[3], YUN GONG[5], XIAO ZHANG[5], Hui Shen[5], Li-Jun Tan[2], Hong-Wen Deng[5], Hong-Mei Xiao[1]. [1]Central South University, China. [2]Hunan Normal University, China. [3]Xiangya Hospital, China. [5]Tulane University, United States. [5]Tulane University,

Osteonecrosis of the femoral head (ONFH) and osteoarthritis (OA) are both degenerative chronic diseases that commonly occur on the femoral head of the hip joint. It is known that ONFH and OA have multiple interconnections and can transform into each other, despite their differences in the etiology, symptoms, and pathogenesis. One of the pathogenic factors considered for both diseases is the disrupted osteogenesis process caused by the dysfunction of bone marrow mesenchymal stem cells (BMMSCs), however, the underlying molecular mechanisms still lack consensus. In this study, we collected and enriched BMMSCs with CD271+ magnetic activated cell sorting (MACS) from human bone marrow sampled from patients with ONFH and OA, respectively. The single-cell RNA sequencing (scRNA-seq) was used to generate the transcriptome landscape of cells in bone marrow environments (BMMSCs, macrophages, neutrophils, and endothelial cells, etc.) under both conditions. Next, we further compared these two conditions and analyzed expression differences and cell-cell signaling communication to reveal the participation of different cell types in the pathogenesis of ONFH. Through this study, we expected to provide a new perspective for understanding the pathological changes of degenerative bone diseases and help for the subsequent diagnosis and treatment development.

A Comparison between Osteogenic Capacities of In-Vitro Cell Cultures and Characteristics of Ex-Vivo Bone Fragments Isolated from Human Acetabular Reamings *Christodoulos Constantinou[1], Michael Kain[2], David Freccero[2], Louis Gerstenfeld[3], Paola Divieti Pajevic[4]. [1]Boston University, United States. [2]Boston Medical Center, United States. [3]Boston University School of Medicine, United States. [4]Goldman School of Dental Medicine, Boston University, United States

Osteoporosis (OP) is a bone disease characterized by a decrease in bone mineral density and changes in bone microarchitecture. In the US, OP affects approximately 10 million people, and subsequently increases their risk of bone fracture. Ongoing research targets the prevention and treatment of OP, primarily through clinical trials. Basic science research is utilized less, in part due to costs, as well as the inaccessibility of human specimen procurement. Therefore, devising an accessible and valid model to investigate bone pathologies at the molecular level will enhance the understanding of the connection between cellular pathology and morbidity, and potentially offer insights into osteoporotic risk factors and prevention. In this study, we isolated bone fragments and mesenchymal stem cells (MSCs) from acetabular reamings procured from human elective total hip arthroplasties. We first extracted RNA from the bone fragments and analyzed gene expression using RT-qPCR. We differentiated the isolated MSCs into osteoblasts, and characterized them for their osteogenic properties through biochemical assays and RT-qPCR. We finally compared data between osteoblasts and bone fragments, and further matched them with the respective patients' demographic and clinical information. Initial analysis using data from 6 patients demonstrated that: a) bone fragments expressed osteogenic gene markers significantly more than the corresponding differentiated MSCs, b) cultured osteoblasts produced alkaline phosphatase and hydroxyproline differentially among patients, but at consistent rates within patients, c) biochemical data from osteoblasts followed trends in osteogenic-marker gene expression of respective bone fragments, and d) osteoblasts potentially follow trends in osteogenic capacities to certain demographics and comorbidities, of which race and BMI are of particular interest. The sample size did not allow for correlational analyses in gene expression to validate primary MSCs' ability to maintain a diseased phenotype outside of their in-vivo environment, and further as a model to study molecular factors of osteoporosis. However, our data suggests that determining osteogenic capacities of cultured and differentiated MSCs may offer critical insight into properties of primary cells isolated from patients. Moreover, these cells can potentially be used as a model to investigate molecular-level pathologies of osteoporosis.

Wnt10b is required for the bone anabolic effect of a natural antibody that blocks oxidized phospholipids. *Michela Palmieri[1], Intawat Nookaev[2], Maria Jose Almeida[3], Ha-Neui Kim[4], Teenamol E Joseph[1], Stavros Manolagas[3], Charles O'Brien[5], Elena Ambrogini[3]. [1]Division of Endocrinology and Metabolism, Center for Musculoskeletal Disease Research, University of Arkansas for Medical Sciences and the Central Arkansas Veterans Healthcare System, United States. [2]2Department of Biomedical Informatics, University of Arkansas for Medical Sciences, United States. [3]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, United States. [4]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States. [5]Univ of Arkansas for Medical Sciences, United States

Oxidized phospholipids containing phosphatidylcholine (PC-OxPLs), present on oxidized low-density lipoproteins (OxLDL) and apoptotic cells, are pathogenic in many diseases, including osteoporosis, atherosclerosis, and non-alcoholic steatohepatitis. OxPLs decrease Wnt and BMP2 signaling, induce ferroptosis and stimulate pro-inflammatory cytokine production. The natural antibody IgM E06 binds PC-OxPLs and blocks their deleterious effects. Transgenic expression of the antigen-binding domain of E06 (E06-scFv) increases bone mass in 6-month-old mice and attenuates high fat diet- and age-induced bone loss by increasing osteoblast number and function. It was shown earlier that E06-scFv upregulates the expression of Wnt10b and Wnt signaling in vivo, but not other Wnt ligands. We investigated the mechanism(s) mediating the anabolic effect of E06-scFv. Single cell RNA-sequencing (scRNA-seq) of mesenchymal cells, isolated from long bones of 7-month-old female mice, revealed a 3-fold increase in Wnt10b expression (adj-P=3.04E-11) in pre-osteoblasts and osteoblasts obtained from E06-scFv transgenic mice compared to cells from WT mice. Wnt target genes were also upregulated. An integrated analysis of 9 published scRNA-seq datasets from bone resident mesenchymal and hematopoietic cell types revealed that the bulk of Wnt10b in the bone microenvironment originates from cells of the osteoblast lineage. Consistent with this evidence, OxLDL decreased Wnt10b and Wnt target genes in calvaria- and bone marrow-derived osteoblastic cell cultures but had no impact on ferroptosis of osteoblastic cells. Moreover, gene expression markers of ferroptosis, as well as BMP2 signaling pathways, were similar in the mesenchymal cells from E06-scFv and WT mice as determined by scRNA-seq. Expression of inflammatory cytokine genes was also similar in vertebral bone by bulk-RNA-seq, and in myeloid cells by scRNA-seq, of WT and E06-scFv mice. To examine the requirement of Wnt10b in the anabolic activity of E06-scFv, we next determined the effect of Wnt10b deletion on the bone phenotype in WT vs E06-scFv transgenic male mice at 6 months of age. We found that both the increase in BMD by DXA and BV/TV of vertebral and femoral cancellous bone by micro-CT were prevented in E06-scFv

transgenic mice lacking Wnt10b. Collectively, these findings indicate that the bone anabolic effect of E06-scFv is due to increased Wnt10b expression that results from removal of the suppressive effects of PC-OxPL.

SUN-317

Inactivation of the Polycomb Repressive Complex 2 in Osteoblasts Increases Trabecular Bone Mass and Results in Mechanically Stronger Bones *Amel Dudakovic[1], Sofia Jerez[1], Christopher Paradise[1], M. Lizeth Galvan[1], Oksana Pichurin[1], Padmini Deosthale[2], Roman Thaler[1], Lilian Plotkin[2], Andre van Wijnen[3]. [1]Mayo Clinic, United States, [2]Indiana University School of Medicine, United States, [3]University of Vermont, United States

Epigenetics, including post-translational modifications of histones, control osteoblast activity and bone formation. The Polycomb Repressive Complex 2 (PRC2) methylates H3 at lysine 27 (H3K27me3), a heterochromatin mark that suppresses gene expression. PRC2 is made of two main structural proteins, Eed and Suz12, and one of two methyltransferases, Ezh1 or Ezh2. We and others showed that Ezh2 inhibition stimulates osteoblast differentiation in vitro and bone formation in vivo. However, Ezh2 loss in osteoblasts (Osx-Cre) is not bone stimulatory in vivo. Thus, the mechanistic understanding of the divergency between Ezh2 inhibition and Ezh2 loss on bone formation remains elusive. These studies build on our findings that Ezh2 is expressed in progenitors while Ezh1 is expressed in committed osteoblasts. We reasoned that loss of the entire PRC2 function will stimulate bone formation. We generated mice in which Ezh1 is depleted globally and Ezh2 is lost in osteoblasts (control = Osx-Cre; Ezh1 KO = Ezh1-/-: Osx-Cre; Ezh2 cKO = Ezh2f/f: Osx-Cre; dKO = Ezh1-/-: Ezh2f/f: Osx-Cre). Ezh1 and Ezh2 dKOs male and female mice exhibited significantly increased trabecular bone (µCT) and bone strength (3-point bending) when compared to controls, Ezh1 KOs, and Ezh2 cKOs (8 weeks). While doxycycline (Cre suppression) prevented this phenotype in dKOs (8 weeks), its removal (8 weeks) to inactivate Ezh2 in osteoblasts (on a Ezh1 null background) lead to a significantly higher trabecular bone mass (14 weeks). We next assessed the effects of targeting PRC2 scaffolding proteins. Eed inhibitors A395 and EED226 enhanced osteogenic differentiation of MC3T3 pre-osteoblasts as assessed by RNA expression (e.g., Bglap and Ibsp) and alizarin red staining (mineral deposition). Similarly, siRNA mediated Eed or Suz12 loss stimulated MC3T3 differentiation. Because Eed can be targeted by small molecules, our initial in vivo studies focused on Eed over Suz12. µCT analysis revealed a significant enhancement of trabecular bone and bio-mechanical bone properties in male and female Eed cKOs (8 weeks). Together, these studies reveal that loss of PRC2 functionality in osteoblasts, through dual Ezh1 and Ezh2 or Eed inactivation, results in high bone mass and mechanically stronger bones. Our findings may enhance the development of novel therapeutic strategies focused on the inactivation of PRC2 to stimulate short-term or sustained bone formation.

Direct Cell Reprogramming to Create Personalized Bone Cell Therapies *Asghar Fallah[1], Peter Kannu[1], Carrie-lynn Soltys[1], Connor Oborn[1], Alex Beke[2], Parker Wengryn[1]. [1]Department of Medical Genetics, University of Alberta, Canada, [2]Department of Medicine, University of Alberta, Canada

Intro: 5-10% of all fractures do not heal causing pain and poor mobility. Currently, there are no treatments for these non-union fractures. Although stem cells are promising, their acquisition is highly invasive. A minimally-invasive alternative utilizes new technology to reprogram patient fibroblasts into a source of therapeutic bone-forming cells-osteoblasts. Therein, we aim to directly reprogram (DR) human fibroblasts into osteoblasts using self-replicating mRNA (srmRNA) for personalized medicine. We hope this will be an effective and safe method to treat fracture non-union clinically.Methods: First, we transduce fibroblasts with an osteoblast-specific reporter system with GFP, enabling the monitoring of differentiation (Fig step1). Next, fibroblast induction into an osteoblastic-state arises through transfection with a custom srmRNA containing OCT4 L-MYC to potentiate multipotency, and RUNX2 and OSX directing cells to an osteoblast fate (Fig step2,3). Adding an interferon blocker (B18R) to media prevents srmRNA degradation and enhances reprogramming. In sum, srmRNA transfection into reporter-integrated fibroblasts, causing reprogramming into osteoblasts; GFP only coexpresses with osteogenic genes, indicating reprogramming. Results: Commercial osteoblasts were transfected with the osteo-specific reporter system, to demonstrate efficacy; GFP expression established significant promoter activity in osteoblasts. RNA gel electrophoresis indicated the successful isolation of srmRNA, based on predicted lengths. Transfection efficiency in fibroblasts was also assessed using various amounts of B18R (200 ng/mL). After 14 days, GFP was expressed in osteo-reporter-transduced cells. After 21 days, alizarin red staining indicated matrix mineralization in reprogrammed fibroblasts (RF), informing osteoblast-like formation. Immunofluorescence analysis of RF showed increased expression of osteoblastic factors, RUNX2 and Osteocalcin. A qPCR analysis of osteoblast marker genes in RF is the next step.Conclusions and future directions: Fibroblasts transfected with osteo-specific srmRNA demonstrated GFP expression and cell matrix mineralization. Suggesting that fibroblasts were successfully reprogrammed to an osteoblast state. We plan to further optimize the process through microRNAs. Single-cell RNA sequencing will also be used for further optimization. We hope that this research lays the groundwork for treatment for non-union fracture.

C-Jun N-terminal Kinase (JNK) Isoform 2 Augments Human Osteoblast Differentiation by Integrating Bone Morphogenetic Protein Signaling and Canonical Notch Signaling *Yadav Wagley[1], Benjamin Graham[2], Kurt Hankenson[2, 1], [2]University of Michigan, United States

The c-Jun N-terminal kinases (JNK) are evolutionary conserved regulators of proliferation, differentiation, and cell death responses. In vivo studies have shown that Jnk1-/- and Jnk2-/- mice display varying degrees of osteopenia due to impaired bone formation. However, JNK1 and JNK2 isoform specific contribution to human osteoblast differentiation is lesser known. Here, we used small interfering RNA-mediated knockdown of JNK1 and JNK2 in bone-marrow derived human mesenchymal stem cells (hMSC) to evaluate their role in BMP-mediated osteoblast differentiation. Histochemical staining for alkaline phosphatase (ALP) expression and extracellular matrix mineralization using Alizarin red S showed that JNK2 activity is essential for hMSC osteoblastic differentiation, whereas JNK1 activity was dispensable. Gene expression analysis revealed a minimal effect on BMP-dependent RUNX2 and SP7 expression after JNK2 knock-down, but their levels were enhanced in JNK1 silenced cells. Since, BMP signaling requires canonical Notch signaling to promote human osteoblastogenesis, we evaluated JNK-isoform specific effects on Notch signaling components. The expression of Notch ligand JAG1 and downstream Notch target genes HES1 and NOTCH3 was reduced in response to BMP stimulation of JNK2 silenced cells, while the effects were modest after JNK1 knock-down. Consequently, the absolute requirement of JAG1 for BMP-mediated hMSC osteoblastogenesis was established as JAG1 silenced hMSC failed to enhance ALP expression and extracellular matrix mineralization. Finally, we generated JNK2-deficient immortalized hMSC using CRISPR-Cas9 genome editing and subjected these cells to BMP2 stimulation. Corresponding to the results with siRNA, JNK2 knock-out cells failed to produce extracellular matrix mineralization in response to BMP2. Collectively, these results establish a regulatory role of JNK2 in human osteoblast differentiation and suggest that it functions by integrating canonical BMP/SMAD signaling and Notch signaling in human cells.

SUN-321

Low, but not High Fluid Shear Stress Affects Matrix Extracellular Phosphoglycoprotein Expression Mainly via Integrin ? Subunits in Preosteoblasts *Jianfeng Jin[1], Hadi Seddiqi[1], Jenneke Klein Nulend[2]. [1]Department of Oral Cell Biology, Academic Centre for Dentistry Amsterdam (ACTA), University of Amsterdam and Vrije Universiteit Amsterdam, Amsterdam Movement Sciences, Netherlands, [2]ACTA-University of Amsterdam and Vrije Universiteit Amsterdam, Netherlands

Introduction: Matrix extracellular phosphoglycoprotein (Mepe) is a member of the extracellular matrix short integrin-binding ligand interacting glycoprotein family of proteins. It plays important multifunctional roles in cell signaling, bone mineralization, and phosphate homeostasis. Mepe expression in bone cells changes in response to pulsating fluid shear stress (PFSS), which is transmitted into cells through integrin-based adhesion sites, i.e., ? and ? subunits. Whether PFSS magnitude controls Mepe expression via modulation of integrin ? and/or ? subunits expression in preosteoblasts is unknown. Therefore, we aimed to test whether low and/or high PFSS affects Mepe expression via modulation of integrin ? and/or ? subunit expression.Methods: MC3T3-E1 preosteoblasts were treated +/- 1h PFSS (0.4 Pa (low-PFSS) or 0.7 Pa (high-PFSS); 1 Hz). Before and after PFSS, cell morphology was observed by light microscopy. Integrin structure was visualized by laser scanning confocal microscopy, and integrin number, area, and fluorescence intensity were quantified by ImageJ. Expression of osteogenic and integrin ? and ? subunit-related genes was assessed by RT-PCR.Results: Preosteoblast morphology, and Runx2, Ki67, Bmp2, Fgf2, Cox2, Dmp1, and Sost gene expression were not affected by low or high-PFSS. Interestingly Mepe gene expression was decreased (0.3-fold) by low, but not high-PFSS. Integrin fluorescence intensity increased (1.1-fold), but integrin area decreased (0.7-0.8-fold) by low and high-PFSS (Fig. 1). Expression of integrin ? subunits 3 and 5-1 was not affected, but integrin ? subunit 5-2 was increased by low (8.0-fold) and high-PFSS (7.3-fold). Expression of integrin ? subunit 1 was increased (2.8-fold) by low-PFSS only, as was expression of integrin ? subunit 1 (2.1-fold) and subunit 3 (5.2-fold). Expression of integrin ? subunit 5 was increased (3.4-

fold) by low/high-PFSS, subunit 5-13 by low (10.8-fold) and high-PFSS (5.2-fold), and subunit 5-123 by low (4.6-fold) and high-PFSS (5.3-fold). Integrin ? subunit 5-12 expression was undetectable.Conclusions: Mepe expression in preosteoblasts was strongly modulated by low, but not high-PFSS. Integrin ? subunit structure and expression were altered by low and high-PFSS, while integrin ? subunit structure and expression were more altered by low-PFSS. This suggests that Mepe-induced changes in preosteoblast mechanosensitivity may drive signaling pathways of bone cell function mainly via integrin ? subunits.

SUN-322

ClC-3 and ClC-5 are essential to drive normal bone mineralization. *Quitterie Larrouture[2], Irina Tourkova[2], Deborah Nelson[3], Paul Schlesinger[4], Harry Blair[2]. [2]University of Pittsburgh, , [2]University of Pittsburgh, United States, [3]University of Chicago, United States, [4]Washington University , United States

Osteoblasts form an epithelial-like layer that separates the extracellular fluid (ECF) that contains the essential components to bone formation from the bone matrix. The production of hydroxyapatite in bone matrix produces a massive number of protons and their removal is essential to avoid stopping the mineralization process. Previously we established that Na/H exchangers 1 and 6 are highly expressed at secretory osteoblast basolateral surfaces and neutralize massive acid loads. We hypothesized that high-capacity proton transport from matrix into osteoblast cytosol must exist to support acid transcytosis for mineral deposition. Gene screening of cultured mineralizing osteoblasts showed dramatic expression of chloride-proton antiporters ClC3 and ClC5. Localization of ClC3 and ClC5 proteins at the apical secretory surface facing the bone matrix was confirmed by antibody labeling, at the EM level, of plasma membrane ClC3, and ClC5, in ClC3 knockout mice (Figure). To study the importance of ClC3 and ClC5 in bone mineralization in vivo and in vitro we used ClC-5 KO mice as well as ClC-3 KO mice. The whole exome sequencing confirmed the deletion of the whole exon 7 in ClC-3 KO mice and the deletion of part of the exon 6 in ClC-5 KO mice. No additional deletions were detected. The ClC-3 KO mice sowed a mildly disordered mineralization (microCT) and serum level of ALP and TRAP compared to WT. Surprisingly, at 3-5 months, body weights of ClC-5 KO females were significantly higher than control mice and 3D morphometry of the lumbar vertebrae showed a significant increase in bone surface/volume ratio in CLC-5 KO mice compared to control. Mass spectrometry-based proteomics confirmed that both KO mice have the presence of modified dysfunctional protein not seen in WT mice). In CLC-3 KO mice the normal CLC-5 protein was increased confirming what we showed previously that cultured ClC-3 KO osteoblasts have an increase in ClC-5 protein expression. After isolation from the bone marrow, CLC-3 KO and CLC-5 KO stromal stem cells were differentiated on PET membrane showing a lower alkaline phosphatase activity, a weak staining with Von Kossa as well as a decrease in collagen production, suggesting a decreased bone turnover. We conclude that regulated acid export, mediated by chloride-proton exchange, is essential to drive normal bone mineralization, and that CLC transporters also regulate fine patterning of bone.Figure: Transmission electron microscopy of mouse vertebrae showing the presence of CLC-5 (immunogold labeling, 12nm) at the apical secretory surface (red arrows) of an osteoblast facing the bone matrix (blue stars).

Muramyl dipeptide enhances bone formation in ovariectomized mice through WNT signaling *Ok-Jin Park[1], Yeongkag Kwon[1], Jiseon Kim[1], Chaeyeon Park[1], Cheol-Heui Yun[1], Seung Hyun Han[1]. [1]Seoul National University, Republic of Korea

Wnt and Nod2 signaling pathways positively regulate bone formation. Here, we investigated whether muramyl dipeptide (MDP), a representative Nod2 ligand, could alleviate post-menopausal osteoporosis through Wnt signaling regulation with an ovariectomy (OVX)-induced mouse osteoporosis model. MDP-administered OVX mice exhibited higher bone volume and mineral density than the control. MDP increased P1NP in the serum and the expression of pGSK3? and ?-catenin in the bone of MDP-administered OVX mice. MDP increased the expression and transcriptional activity of ?-catenin but inhibited the proteasomal degradation of ?-catenin via down-regulating its ubiquitination by GSK3? inactivation in osteoblasts. The induction of pAKT, pGSK3?, and ?-catenin by MDP was not observed in Wnt signaling inhibitor-pretreated osteoblasts or Nod2-deficient osteoblasts. MDP-administered OVX mice exhibited fewer osteoclasts than OVX mice with a decrease in the RANKL/OPG ratio. Conclusively, MDP alleviates estrogen deficiency-induced osteoporosis through canonical Wnt signaling and could be an effective therapeutic against postmenopausal bone loss.

Non-thermal atmospheric plasma induces osteogenic activity in osteoblasts through WNT signaling Pathway *Ashish Ranjan Sharma[1], Supriya Jagga[2], Yeon-Hee Lee[3], Sang-Soo Lee[4]. [1]Hallym University, Republic of Korea, [2]Harvard University, United States, [3]Hallym university , Republic of Korea, [4]Hallym university, Republic of Korea

Non-thermal plasma (NTP: an ionized gas) is being employed for the biological and medical treatment of living tissues. Plasma is composed of free charges (electrons, ions), and free radicals, generating a transient electric field. Reactive oxygen and nitrogen species (ROS and RNS) produced by NTP are thought to be the primary factors that interact with the proteins to exert their biological effects. NTP has been reported as a potent stimulator for various biological activities, like anticancer, sterilization, promoting wound healing, etc. Recent studies have shown a positive effect of NTP on osteogenic induction in stem cells and bone regeneration. However, a clear insight into the mechanism of action of NTP on the osteoblasts is still warranted. Two types of (dielectric barrier discharge (DBD) or Jet) NTPs were treated to serum-free cell culture media with various time intervals (5, 10, 20 min) to generate various plasma-media interfaces for ion exchange. Ionized media showed no mitogenic or cytotoxic effects on murine preosteoblast cells, MC3T3 E-1. Among various NTP ionized mediums, Jet NTP medium (JNTPM, 10 min) showed induction of ALP activity of preosteoblasts after 48 h of treatment. A dose-dependent (% of JNTPM to complete medium) treatment of JNTPM to MC3T3 E-1 cells demonstrated an increased ALP activity from 25%

to 100% of media treatment. Since 25% of JNTPM was enough to induce maximum ALP activity in preosteoblasts, 25% of JNTPM was used for further experiments. Apart from ALP activity, JNTPM enhanced the mRNA expressions of osteogenic markers of osteoblasts like Osterix, Runx-2, bone sialoprotein, Collagen 1, and osteopontin. Moreover, the 7 d JNTPM-treated MC3T3 E-1 cells showed increased collagen synthesis and mineralization. Treatment of JNTPM to MC3T3 E-1 cells transfected with Axin-2 reporter construct showed time-dependent increased reporter activity, implying activation of the Wnt signaling pathway. The increased stabilization of ?-catenin and phosphorylation of GSK3-? further corroborated the activation of Wnt signaling. An N-acetyl-l-cysteine (NAC) treatment suppressed the Axin-2 reporter activity and stabilization of ?-catenin in JNTPM-treated MC3T3 E-1 cells, suggesting a role of ROS in the induction of Wnt signaling and thus osteogenic activity in preosteoblasts. Thus, further studies are required to delineate the cross-talk between ROS and Wnt signaling to understand the osteogenic stimulatory properties of JNTP.

Mitochondrial dysfunction and integrated stress response in G610C mouse osteoblasts *Elena Makareeva[1], Megan Sousa[1], Laura Gorrell[1], Shakib Omari[1], Satoru Otsuru[2], Sergey Leikin[1]. [1]National Institutes of Health, United States, [2]University of Maryland, United States

Osteoblast cell stress caused by the misfolding of procollagen has been shown to be an important factor in bone pathology resulting from Gly substitutions in osteogenesis imperfecta (OI). Our previously published studies of G610C mice with a Gly610Cys substitution in the triple helical region of the ?2(I) chain of type I collagen revealed increased EIF2? phosphorylation and ensuing integrated stress response (ISR) in osteoblasts without upstream unfolded protein response (UPR). Instead, upregulated expression of Hspa9 and Atf5 encoding mitochondrial paralogues of BIP and ATF4 suggested mitochondrial involvement in the ISR activation, probably via disruption of ER-mitochondria contacts. In the present study, we tested this hypothesis in primary osteoblast cultures by investigating which of the four EIF2? kinases activate the ISR and by imaging mitochondrial dynamics, ATP, and reactive oxygen species (ROS). We observed altered mitochondrial fission, increased ROS production in differentiating osteoblasts, reduced ATP synthesis in mature cells, and EIF2? phosphorylation by GCN2 rather than PERK in response to the G610C mutation. Taken together with our published studies of G610C procollagen trafficking in osteoblasts, these observations suggest the following ISR activation mechanism. Like all secretory proteins, the procollagen precursor of collagen is folded in the ER and exported through ER exit sites (ERESs). Its triple helix misfolding, however, is detected at ERESs rather than in the ER lumen. Blockage and depletion of functional ERESs due to the retention of misfolded procollagen by ERESs disrupts the exit of all secretory proteins and causes their accumulation in the ER. The resulting ER dilation disrupts ER-mitochondria contacts, leading to mitochondrial dysfunction and activation of the mitochondrial, not ER, arm of the ISR, in which EIF2? is phosphorylated by GCN2 rather than PERK. This novel pathway of ISR activation by secretory protein misfolding in the ER may present new opportunities for therapeutic targeting of osteoblast malfunction in classical OI.

SUN-327

Orphan GPCR, Gprc5a, is a novel parathyroid hormone-inducible gene and negatively regulates osteoblast proliferation and differentiation in osteoblast-like MC3T3-E1 cells. *Chisato Sampei[1], Kosuke Kato[1], YASUHIRO ARASAKI[2], Yuta Kimura[1], Takuto Konno[1], Kanon Otsuka[1], Masaki Noda[3], Yoichi Ezura[4], Yukihiro Kohara[1], Tadayoshi Hayata[5]. [1]Tokyo University of Science, Japan, [2], Japan, [3]Tokyo Medical and Dental University, Japan, [4]Tokyo Medical and Dental University, Medical Research Insititute, Japan, [5]Graduate School of Pharmaceutical Sciences and Faculty of Pharmaceutical Science, Tokyo University of Science, Japan

Teriparatide is a peptide derived from a parathyroid hormone (PTH) and is an osteoporosis therapeutic drug with potent bone formation-promoting activity. However, its pharmacological actions are not fully understood. To better understand the mechanism of action of teriparatide and identify novel druggable genes that act downstream of PTH signaling, we conducted a screening of teriparatide target genes in mouse osteoblast-like MC3T3-E1 cells. Here we show that Gprc5a, an orphan G protein-coupled receptor is a novel teriparatide-inducible gene and negatively regulates osteoblast proliferation and differentiation. Gprc5a expression was induced by teriparatide in MC3T3-E1 cells, rat osteosarcoma ROS17/2.8 cells, and rat femur. Induction of Gprc5a expression by teriparatide occurred in the absence of protein synthesis and was mediated via the cAMP pathway, suggesting that Gprc5a is a direct target of PTH signaling. Interestingly, Gprc5a expression was induced synergistically by co-treatment with teriparatide and 1?, 25-Dihydroxyvitamin D3 (calcitriol), or retinoic acid in MC3T3-E1. Reporter analysis of a 1 kb fragment of human GPRC5A promoter revealed that the promoter fragment showed responsiveness to teriparatide via the cAMP response element, suggesting that GPRC5A is also a PTH-inducible gene in humans. Gprc5a knockdown promoted cell viability and proliferation, as demonstrated by MTT and BrdU assays. Gprc5a expression was reduced during osteoblast differentiation. Lentivirus-mediated overexpression of Gprc5a suppressed osteoblast differentiation, as indicated by gene expression analysis and mineralization assay. Mechanistic studies showed that Gprc5a interacted with BMPR1A and suppressed BMP signaling induced by BMP-2 and constitutively active BMP receptors, ALK2 (ACVR1) Q207D and ALK3 (BMPR1A) Q233D. Thus, our results suggest that Gprc5a is a novel gene induced by teriparatide that acts in an inhibitory manner on both cell proliferation and osteoblast differentiation and is a candidate for drug targets for osteoporosis.

Role of the N-glycosylation Sites for Enzymatic Activity of Tissue-Nonspecific Alkaline Phosphatase and Presence of Bone-Specific Isoforms *Diana Atanasova[1], Lavanya Moparthi[2], Stefan Koch[2], Marwa Abdul Hamid[1], Eva Landberg[1], Sonoko Narisawa[3], José Luis Millán[3], Per Magnusson[1]. [1]Department of Clinical Chemistry, and Department of Biomedical and Clinical Sciences, Linköping University, Sweden, [2]Wallenberg Centre for Molecular Medicine, and Department of Biomedical and Clinical Sciences, Linköping University, Sweden, [3]Sanford Children's Health Research Center, Sanford Burnham Prebys Medical Discovery Institute, United States

Tissue-nonspecific alkaline phosphatase (TNALP) expressed by osteoblasts is known as bone-specific alkaline phosphatase (BALP). BALP is a membrane-bound glycoprotein that facilitates bone mineralization by hydrolysis of the mineralization inhibitor pyrophosphate and of ATP to provide inorganic phosphate, thus controlling the PPi/Pi ratio to enable hydroxyapatite formation. To date, four BALP isoforms can be quantified in serum by HPLC based on different N-linked glycosylation properties. Commercial immunoassays are currently available for the measurement of BALP which reflects bone formation. However, these assays cannot distinguish the individual BALP isoforms. A novel approach to detect the individual BALP isoforms could be to target specific glycoprotein motifs. We have previously demonstrated that all five sites of BALP located at N140, N230, N271, N303 and N430 are glycosylated. In this study, we aimed to study how the five N-glycosylation sites affect the BALP isoform profile with Western blot, enzymatic activity and HPLC after site-directed mutagenesis. The five asparagine (N)-glycan sites were substituted with glutamine (Q) or aspartic acid (D) in the following mutations: N140Q, N230Q, N271Q, N303Q and N430D. Both single and multiple mutations were generated in a human TNALP-expressing plasmid and expressed in Alpl-/- mouse calvarial osteoblasts. Herein, we found that mutating a single N-glycan site did not influence the expression, activity or isoform profile of the expressed BALP in comparison with WT. However, the double substitution of N230Q/N271Q led to decreased protein expression and 9% residual enzymatic activity of WT. N271Q/N303Q and N303Q/N430Q had 57% and 79% residual activity, respectively. N140Q/N230Q, N230Q/N430D and N271Q/N430D slightly changed the activity. The BALP isoform analysis by HPLC of both single and double mutations showed similar BALP isoform patterns as WT. However, a shift in retention time was observed in the double mutations. In conclusion, the presence of BALP isoforms is not dependent on a single N-glycan site. The N-glycan sites N230 and N271 are pivotal for normal activity of BALP. Low BALP protein amounts were found when three N-glycan sites were mutated, which suggests that these N-glycan sites are needed for stable protein expression. Additional studies are needed to understand the structural and functional differences of N-linked glycosylation among the BALP isoforms.

Targeted Expression of Claudin (Cldn)-11 in Osteoblasts Increases Trabecular Bone Mass by Stimulating Bone Formation and Reducing Marrow Adiposity in Mice *Weirong Xing[1], Sheila Pourteymoor[2], William Tambunan[2], Subburaman Mohan[3]. [1]Musculoskeletal Disease Center, Jerry L. Pettis Memorial Veteran s Admin., United States, [2]VA Loma Linda Healthcare System, United States, [3]Jerry L. Pettis Memorial VA Medical Center, United States

The claudin (CLDN) family comprises 24 members of 20-34 kDa tetraspan transmembrane proteins of tight junctions. In addition to their established canonical role as barriers controlling the flow of molecules in the intercellular space between cells, a distinct non-canonical role for CLDNs is now emerging in which they serve as mediators of cell signaling. In previous studies, we showed that mice with global deletion of Cldn-11 gene exhibited reduced trabecular bone mass. However, the impact of Cldn11 expression osteoblast lineage cells in vivo remains undefined. Here, we generated osteoblast-specific transgenic lines expressing Cldn11 transgene driven by the ColCAT2.3 promoter and characterized their skeletal phenotype. Micro-CT analysis of distal femoral metaphysis showed that trabecular bone mass was increased by 50% and 38% (both $P<0.01$, n=8-10 per gender), respectively, in the transgenic male and female mice compared to littermate control mice that was caused by a significant increase in trabecular number and reduction in trabecular separation. Trabecular bone mass was also increased by 43% ($P<0.01$) in the proximal tibial metaphysis of transgenic mice of both genders. Histology and serum biomarker studies revealed that increased bone formation, and not reduced bone resorption, is the cause for increased trabecular bone mass in the Cldn11 Tg mice. Accordingly, expression levels of bone formation (Alp, Bsp) but not bone resorption (Ctsk) markers were increased in the bones of Cldn11 transgenic mice. Since bone marrow stromal cells are common precursors for osteoblasts

and adipocytes and marrow adipose tissue (MAT) is known to correlate with trabecular bone mass inversely, we measured MAT by micro-CT of osmium tetroxide labeled bones. MAT was reduced by 86% (P<0.05) in the proximal tibia of transgenic male mice compared to control mice. Accordingly, the expression levels of the adipogenic markers (adiponectin and Asc1) and regulators of MAT (adipsin and leptin), were significantly reduced by 45-53% (P<0.05) in the bones of transgenic male mice. Our data are consistent with the possibility that CLDN11 exerts anabolic effects in osteoblasts by promoting the differentiation of mesenchymal stem cells towards osteoblasts at the expense of adipocytes.

Functional Validation of Dock9 as a Potential Regulator of Bone Mass with In Vitro and In Vivo Models *Gregory Ottenberg[1], Megan Kraus[1], Dana Godfrey[1], Larry Messner[2], Charles Farber[2], Cheryl Ackert-Bicknell[1]. [1]University of Colorado, United States. [2]University of Virginia, United States

We previously identified osteoblast gene expression gene network modules enriched for genes identified by human genome wide association studies (GWASs) as being associated with bone mineral density (BMD). One module core gene was Dock9, a cell signaling gene that acts on G proteins. Data from International Mouse Phenotyping Consortium suggested that loss of this gene impacted BMD, but this result required validation. We used CRISPR-Cas9 to generate Dock9-/- mutant mice and body composition was measured via DXA in 12-week-old mice. In Dock9 -/- mice, there was an increase in BMD in both males (Dock9-/- = 79.7?3.3 mg/cm2 vs Dock9+/+ = 69.7?3.8 mg/cm2, p = 0.08) and females (Dock9-/-=77.4?2.8 mg/cm2 vs Dock9+/+= 59.4?2.1 mg/cm2, p<0.001), with no increase in bone area (female p = 0.32, male p = 0.95). Female, but not male mice showed an increase in lean mass (Female Dock9-/- = 17.5?0.6g vs Dock9+/+ = 14.8?1.4g, p = 0.011, Male p=0.44), but no difference in fat mass (not shown). Calvarial derived osteoblasts were isolated from neonates and mineralization was monitored in a time course manner using the calcium binding IRDye 800CW BoneTag (Licor). We saw delayed mineralization in Dock9-/- osteoblasts vs Dock9+/+ cells but no change in the rate of mineralization. This resulted in an overall reduction in mineralization (Fig 1 A). To confirm this effect, murine MC3T3-E1 pre-osteoblast cells were treated with siRNAs targeted to Dock9. Western Blots confirmed that DOCK9 was knocked down by Dock9 siRNAs compared to scrambled siRNA controls (Fig 1B). We again observed delayed mineralization, but no change in the rate (Fig 1 C&D.) This resulted in less mineralization in the Dock9 deficient cells as validated by Alizarin Red at the end of the experiment. Quantitative PCR revealed a transient effect on Dock9, Sp7, and Runx2 expression in the siRNA treated cells. Available RNAseq data shows that Dock9 is not expressed in osteoclasts but is expressed highly in osteoblasts and osteocytes. Collectively, our data cannot explain the increased BMD in the absence of Dock9, but do show a primary impact on osteoblast function. This confirms why Dock9 featured prominently in our network analysis and substantiates this gene is a candidate for the BMD GWAS locus. Future studies will investigate if there is in an increase in osteoblast number in vivo increasing overall mineralization, or a suppression of resorption via crosstalk that could explain this increase in BMD.

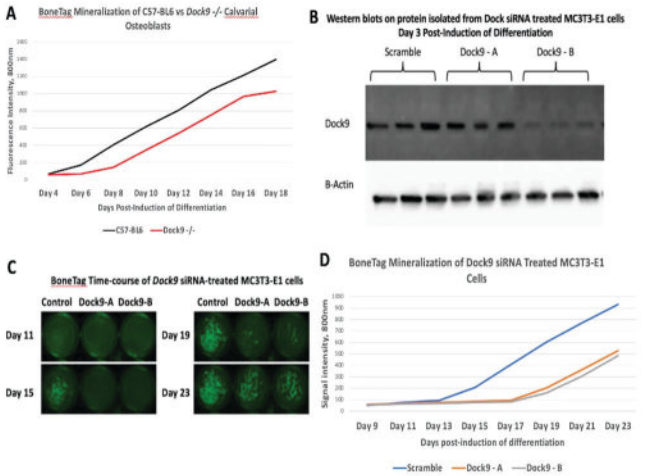

Figure 1: A) Mineralization assay showing delay of onset of mineralization in *Dock9-/-* calverial osteoblasts. B) Western Blot results showing decrease of *Dock9* expression after siRNA treatment. C) BoneTag images of MC3T3-E1 cells after *Dock9* siRNA treatment. D) Mineralization assay showing delay of onset of mineralization in MC3T3-E1 cells after *Dock9* siRNA treatment.

Azilsartan Inhibits Inflammation-Triggered Bone Resorption and Osteoclastogenesis in vivo via Suppression of TNF-? Expression in Macrophages *ZIQIU FAN[1], Hideki Kitaura[4], Jiayi REN[3], Fumitoshi Ohori[1], Takahiro Noguchi[1], Aseel Marahleh[4], Jinghan Ma[4], Kayoko Kanou[1], Mariko Miura[1], KOHEI NARITA[1], Itaru Mizoguchi[1]. [1]Tohoku University Graduate School of Dentistry, Japan. [4]Tohoku University, Japan. [3]Graduate School of Dentistry, Tohoku University, . [4]Tohoku University,

Introduction: Hypertension is a major risk factor for cardiovascular disease (CVD) and is associated with increased bone loss due to excessive activity of the local renin-angiotensin system (RAS). Angiotensinogen/Angiotensin (ANG) II/Angiotensin II type 1 receptor (AT1R) axis is considered as the core axis regulating RAS activity. Azilsartan is an FDA-approved selective AT1R antagonist that is used to treat hypertension. This study aimed to determine whether azilsartan affects formation of osteoclast, resorption of bone, and the expression of cytokines linked with osteoclastogenesis during lipopolysaccharide (LPS)-triggered inflammation in vivo. Methods: Following a 5-day supracalvarial injection of LPS with or without azilsartan, the proportion of bone resorption and number of osteoclasts were counted. In vitro, the effect of azilsartan on RANKL-or TNF-?-triggered osteoclastogenesis was investigated. Also, whether azilsartan restrains LPS-triggered TNF-? mRNA expression in macrophages and RANKL mRNA expression in osteoblasts were assessed. Results: Azilsartan-treated calvariae exhibited significantly lower bone resorption and osteoclastogenesis than those treated with LPS alone. In vivo, LPS with azilsartan administration resulted in lower levels of receptor activator of NF-?B ligand (RANKL) and tumor necrosis factor-alpha (TNF-?) mRNA expression than LPS administration alone. Nevertheless, azilsartan did not show inhibitory effect on RANKL- and TNF-?-triggered osteoclastogenesis in vitro. Compared to macrophages treated with LPS, TNF-? mRNA levels were lower in macrophages treated by LPS with azilsartan. In contrast, RANKL mRNA expression levels in osteoblasts were the same in cells co-treated with azilsartan and LPS and those exposed to LPS only. Conclusion: These findings imply that azilsartan prevents LPS-triggered TNF-? production in macrophages, which in turn prevents LPS-triggered osteoclast formation and bone resorption in vivo.

Identification of glutamine metabolism as a metabolic vulnerability in osteoclasts *GUOLI HU[1], Yilin Yu[3], Robert Tower[3], Guo-fang Zhang[4], Courtney Karner[3]. [1]UT Southwestern Medical Center, . [3]University of Texas Southwestern Medical Center, United States. [3]University of Texas Southwestern Medical Center, . [4]Duke University, United States

Osteoclasts are bone resorbing cells that are essential to maintain skeletal integrity and function. Excessive osteoclast activity causes both age-related and pathological bone loss associated with several diseases including osteoporosis. While many of the growth factors and molecular signals that govern osteoclastogenesis are well studied, a large gap in our knowledge exists about the role and regulation of cellular metabolism during osteoclastogenesis. Advances in our understanding of differentiation associated metabolic changes will aid in identifying metabolic vulnerabilities that can be exploited therapeutically to reduce bone resorption and pathological bone loss. Here, we used a multifaceted approach to define the metabolomic signature of osteoclasts. When compared to bone marrow monocyte and macrophage cultures, mature osteoclasts (mOC) have significantly increased abundance of amino acids and purine and pyrimidine nucleotides. Osteoclasts must increase the consumption and metabolism of glutamine which provides carbon and nitrogen for amino acid and nucleotide biosynthesis. Importantly, inhibiting glutamine metabolism in mOC resulted in a complete loss of the metabolomic signature and prevented osteoclast differentiation in vitro. Deletion of a floxed Gls allele (Glsfl) in myeloid progenitor cells using LysmCre resulted in significantly higher bone mass at 4- and 6-months of age in male and female mice. The LysmCre;Glsfl/fl bone phenotypes were attributed to a reduction in osteoclast numbers and bone resorption with no change osteoblast parameters. Conversely, expressing a doxycycline inducible Gls allele (tetoGls) using LysmCre (LysmCre;R26rtTA;tetoGls) increased osteoclastogenesis, enhanced bone resorption and rapidly reduced bone mass. Highlighting the therapeutic implications of these findings, genetically inhibiting glutamine metabolism prevented ovariectomy induced bone loss in mice. Collectively, our data provide genetic evidence that glutamine metabolism is essential to regulate osteoclast metabolism, osteoclastogenesis and bone resorption in mice. Moreover, our study demonstrates osteoclasts are reliant on glutamine metabolism like cancer cells. Targeting glutamine dependency using Telaglenastat is being developed as a potential cancer treatment. Our findings indicate it may be possible to repurpose this strategy to prevent excessive bone resorption.

IGFBP regulates osteoclast differentiation. *Yusaku Hamada[1], Takashi Izawa[2], Yuri Yoshikawa[1], Gohji Kozaki[1], Hiroshi Kamioka[3]. [1]Department of Orthodontics, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Japan. [2]Okayama University Grad Sch, Japan. [3]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sc, Japan

Global deletion of the Igfbp gene results in the suppression of bone turnover. To investigate the role of insulin-like growth factor binding protein (IGFBP) in regulating osteoclast differentiation, we cultured Igfbp?/? bone marrow macrophages (BMMs) and found a reduction in the number of osteoclasts and impaired resorption. To determine the molecular domains of IGFBP that were required for this effect to be manifest, Igfbp?/? BMMs were transfected with constructs which the IGF-binding domains or the thyroglobulin type-1 domain of IGFBP were deleted. We found that both domains were necessary for osteoclastogenesis because expression of the deletion forms of either domain failed to support the formation of functionally mature osteoclasts. Next, to examine whether IGFBP overexpression enhances RANKL-induced osteoclastogenesis, we retrovirally transduced IGFBP into WT BMMs and stimulated with RANKL. Upon RANKL treatment, BMMs transduced with IGFBP-WT vector underwent osteoclastic differentiation more readily and increased bone resorption activity when compared with the BMMs transduced with empty vector. Furthermore, recombinant IGFBP enhance the RANKL-induced osteoclastogenesis in a dose dependent manner. Finally, to discern the mechanism by which IGFBP regulates osteoclast formation, phosphorylation of Akt respond to IGF-I were analyzed. We concluded that IGFBP is an important regulator of osteoclastogenesis and both the IGF-binding domain and the thyroglobulin type-1 domain of IGFBP are essential for the formation of fully differentiated and functional osteoclasts.

A Novel Fluorogenic Probe for Intravital Microscopic Imaging of Enzymatically Active Cathepsin K in Functional Osteoclasts *Eun Jung Lee[1], Seyoung Koo[2], Da Hyeon Yoon[1], Jong Seung Kim[2], SERK IN PARK[1]. [1]Korea University College of Medicine, Republic of Korea. [2]Department of Chemistry, Korea University, Republic of Korea

Cathepsin K (CTSK) is a lysosomal cysteine protease that is essential to the osteolytic activity of functional osteoclasts. Several fluorescence-based probes for CTSK have been developed for preclinical studies on osteoclast inhibitors but the sensitivity and signal intensity are insufficient for real-time live imaging in mice. To overcome this limitation, we synthesized a novel fluorescence resonance energy transfer (FRET)-based fluorogenic CTSK probe and tested its efficacy in vitro using a confocal microscope and in vivo using an intravital microscope. A peptide substrate specific to CTSK was conjugated with a TAMRA fluorophore and a BHQ-2 quencher. Upon addition of a nano-molar range of recombinant CTSK, the TAMRA fluorophore was cleaved from the quencher, resulting in a strong fluorescence signal, which was fully suppressed by odanacatib, a CTSK inhibitor. Notably, our probe exhibited over 60-fold higher sensitivity than previously reported probes. For in vitro imaging, osteoclasts were formed by treating murine bone marrow monocytes with RANKL and M-CSF on collagen-coated plates or dentin discs, followed by fixation, permeabilization and staining with the probe, phalloidin and DAPI. Confocal microscopy demonstrated the subcellular localization of CTSK in osteoclasts (Figure Panel A). A strong fluorescence signal was localized in the ruffled border, indicating that the probe is sensitive and specific to functional CTSK in bone-resorbing osteoclasts. For intravital imaging, we used three different mouse models: an ovariectomy-induced osteoporosis model, a RANKL injection bone loss model, and a bone metastasis model using intra-tibial injection of breast tumor cells. The CTSK probe was administered by tail-vein injection (50?mol), and live real-time images were captured in the proximal tibia with a small skin incision under anesthesia. No significant toxicities were noted in multiple injection groups of mice. Two-photon intravital microscopy showed clear real-time images of osteoclasts on the endosteal surface or trabecular bone of live animals (Figure Panel B). The fluorescence signal was not detectable in negative control mice, and the signal was significantly reduced in mice treated with zoledronic acid or odanacatib. In conclusion, we developed a novel probe for sensitive and specific visualization of functional CTSK in real-time live mice that can be useful in bone biology research and in the development of therapeutics for CTSK or osteoclasts.

SUN-340

Even in the absence of RANKL and serum, human bone resorbing osteoclasts in vitro are more active when female donors are 60 to 80 years compared to 25-30 years of age *Neha Sharma[1], Jacob B. Olesen[2], Pernille Hermann[3], Julie Therese Skaugen[4], Line Strand Andersen[4], Torben Barington[4], Megan Weivoda[5], Kent Soee[1]. [1]Clinical Cell Biology, Dept. of Pathology, OUH/SDU; Dept. of Clinical Research, SDU; Dept. of Molecular Medicine, SDU, Denmark. [2]Clinical Cell Biology, Dept. of Pathology, OUH/SDU, Denmark. [3]Dept. of Endocrinology, OUH, Odense, DK, Denmark. [4]Dept. of Immunology, OUH, Denmark. [5]Dept. of Hematology, Mayo Clinic, United States

Previously, we reported that the bone resorptive activity of human osteoclasts (OCs) increases with age of the donor, especially caused by OCs making trenches. We are interested in investigating whether the age of the donor has such a strong impact on bone resorbing OCs in vitro that it would still be observed in the absence of fetal bovine serum (FBS) and RANKL.12 female donors were recruited, CD14+ monocytes from their blood were differentiated into OCs using 25 ng/ml M-CSF & RANKL and 10% FBS over 9 days in vitro. OCs were detached, split in two and reseeded at a density of 50,000 cells per bovine bone slice and cultured either 1) with 25 ng/ml M-CSF & RANKL and 10% FBS or 2) with only 25 ng/ml M-CSF. After 72h, conditioned media was collected for TRAcP-activity measurement. Bone resorption was visualized using toluidine blue and bone erosion was quantified using a light microscope, a 100-point grid, and were categorized into pits and trenches. Bone resorption was analyzed in a blinded manner.Group 1 (G1, 25-35 years) and Group 2 (G2, 60-80 years). Osteoclastic bone resorption conducted in the presence of FBS and RANKL clearly showed that OCs from G2 (n=7) were more active than those from G1 (n=5) - and especially made more trenches: 1) eroded surface(ES)/bone surface(BS), G1 3.7% vs G2 6.4%, p=0.005; 2) trench surface(TS)/BS, G1 1.1% vs G2 3.2%, p=0.001); 3) pit surface(PS)/BS, G1 1.5% vs G2 3.0%, p=ns; 4) TS/ES, G1 38.1% vs G2 58.1%, p=0.001. TRAcP activity was 6.4 times higher in G2 compared to G1 (p=0.0002). Osteoclastic bone resorption conducted in the absence of FBS and RANKL gave very similar results showing that OCs from G2 (n=7) were more active than from G1 (n=4): 1) ES/BS, G1 0.7% vs G2 2.2%, p=0.005; 2) TS/BS, G1 0.3% vs G2 0.8%, p=0.005; 3) PS/BS, G1 0.3% vs G2 1.2%, p=0.005; 4) TS/ES, G1 44.2% vs G2 57.8%, p=ns). TRAcP activity was 6.5 times higher in G2 compared to G1 (p=0.03).In conclusion, we replicate our previous findings that increasing age results in more aggressive bone resorbing OCs in vitro and that this is primarily mediated through trench making OCs, in the presence of RANKL and FBS. In their absence, bone resorption is highest in G2, but this seems to be caused both by OCs making pits and trenches. This is an ongoing study and more donors need to be recruited in order to make firm conclusions, but it is clear that increasing age of donor enhances osteoclastic bone resorption in vitro, even in the absence of RANKL and FBS.

Pim1 contributes to maintenance of bone homeostasis via regulation of osteoclast function *Soo Young Lee[1], Ryeojin Ko[1], Jeongin Seo[1]. [1]Ewha Womans University, Republic of Korea

ObjectiveThe proviral integration site for Moloney murine leukemia virus 1 (Pim1) protein is a highly conserved serine/threonine kinase that is involved in a variety of cellular processes including cell survival, proliferation, and apoptosis. In addition, Pim1 has been shown to regulate the differentiation of osteoclasts. Mature osteoclasts absorb bone matrix by forming an actin ring between themselves and the bone surface. However, the role of Pim1 in the bone-resorbing function of osteoclasts is largely unknown.MethodsIn this study, we generated Pim1-/- mice to investigate the role of Pim1 in the regulation of bone metabolism. We conducted immunofluorescence staining of actin and acetylated tubulin in osteoclast on dentin slices and coverslips in wild-type and Pim1-/- mice. To identify whether Pim1 deletion affects bone growth in vivo, we examined the microstructure of the distal femur from 8 weeks old male mice wild-type and Pim1-/- mice using micro-computed tomography (micro-CT) analysis.ResultsWe demonstrated that Pim1 deletion does not affect the differentiation of osteoclasts. However, a significant reduction in resorption area was observed in Pim1-/- mice. In addition, Pim1-deficient osteoclasts were unable to form normal actin rings, and the acetylation pattern of microtubules was abnormal. Furthermore, an increase in distal femoral bone mass was observed in Pim1-/- mice compared to wild-type mice.Conclusions-These results indicate that Pim1 plays an important role in the bone-resorbing function of osteoclasts. Therefore, the control of osteoclast activity via targeting Pim-1 will provide a novel therapeutic option for the treatment of bone diseases.

SUN-343

Orthosilicic Acid Inhibits Human Osteoclast Differentiation and Bone Resorption *Catarina Magnusson[1], Maria Ranjö[2]. [1]Institute of Odontology, Sahlgrenska Academy, University of Gothenburg, Sweden. [2]Institute of Odontology, Sahlgrenska Academy, University of Gothenburg / Department of Odontology, Umeå University, Sweden

Silicon (Si) is a mineral found in our diet and is also present in some bone substitute materials used in the treatment of craniofacial and dentoalveolar bone defects. The bioavailable form of Si and hence, the form with biological relevance, is orthosilicic acid [Si(OH)4]. In vitro studies investigating the effect of Si on osteoblast-like cells have shown osteogenic properties with increased differentiation and function. We have demonstrated that Si inhibits osteoclast differentiation in mouse cells either co-culture from bone marrow (Mladenovic Z et al., Acta Biomater. 2014) or in a monocyte/macrophage cell line (Magnusson C et al., J Biomed Mater Res A. 2021). The present study aimed to further investigate the direct effects of Si on osteoclast differentiation, gene expressions, and bone resorption in human osteoclast precursors.Human CD14+ monocytes were isolated from buffy coat and cultured with M-CSF (25 ng/ml) and RANKL (2 or 25 ng/ml) in medium without or with Si (50 ?g/ml; constituting 75% OSA). The effects of Si on osteoclast differentiation were evaluated by TRAP-staining and the expression of DC-STAMP, cathepsin K, TRAP, and calcitonin receptor by RT-qPCR. The effect of Si on the gene expression of aquaporin9, a potential Si transporter, was also analysed. Bone resorption was determined by the number of resorption pits formed when the cells were cultured on bone slices, and the amount of type I collagen fragments released in the cell culture medium.Silicon inhibited the number of TRAP+ multinucleated cells and significantly inhibited the expression of osteoclast related genes, but increased the expression of aquaporin9. Furthermore, Si significantly inhibited the number of resorption pits and the amount of collagen fragments in the culture medium when cells were cultured on bone slices.In conclusion, our results indicates that orthosilicic acid inhibits osteoclast differentiation and bone resorption in RANKL-stimulated primary human monocytes and that aquaporin9 may facilitate the transmembrane transport of Si.

Transcriptional Reprograming during Human Osteoclastogenesis Identifies Targets for Predicting and Modulating Osteoclast Differentiation and Activity *Morten S. Hansen[1], Kaja Madsen[2], Maria Price[3], Kent Søe[1], Caroline M. Gorvin[3], Morten Frost[1], Alexander Rauch[2]. [1]Odense University Hospital, Denmark. [2]University of Southern Denmark, Denmark. [3]University of Birmingham, United Kingdom

Background: Increased osteoclastogenesis and osteoclast activity are important causes of postmenopausal osteoporosis. Understanding the transcriptional reprogramming during osteoclastogenesis has the power to identify targets for novel anti-osteoporotic drugs.Purpose: Define gene expression dynamics during human osteoclast differentiation for the alignment with bone mineral density related expression and GWAS data, the construction of transcriptional networks and the identification of G-protein-coupled receptors and surface molecules that allow interference with osteoclast activity and the prediction of subject-specific resorptive potential.Methods: Human osteoclasts were differentiated (t=10 days) in vitro from CD14+-monocytes from eight female donors aged 18-49 years. RNA-sequencing was performed at four time points (day 0 prior to and 2-, 5-, and 9-days post-differentiation). GPCRs were targeted with agonist and/or antagonists and FACS based surface molecule expression was determined in relation to bone resorbing activity.Results: We identified 8446 differentially expressed genes with high reproducibility across donors that were grouped into eight temporal patterns which based on network analysis are linked by mutual and temporal dependencies. These patterns were enriched for distinct molecular functions, metabolic pathways, and genes that are flanked by bone mineral density associated SNPs. Compared to normal, osteoporotic bones exemplified gene signatures of mature osteoclasts and absence of precursor related genes. Using pharmacological interference with differentially expressed GPCRs, we found activation of somatostatin receptor 2 (SSTR2) to decrease osteoclast resorption, activation of free fatty acid receptor 4 (FFAR4/GPR120) to decrease both osteoclast numbers and activity, and activation of complement C5a receptor 1 (C5AR1) to increase osteoclast numbers. FACS analysis affirms expression of oxidised LDL receptor 1 (LOX1) and activated CDC42 kinase 1 (ACK1) on precursors to be correlating with activity of the mature cells. Conclusions: We provide a consecutive map of the transcriptional reprogramming during human osteoclastogenesis that highlights the strong implication of osteoclast genes in the aetiology and genetics of human bone loss. Targeting stage specifically expressed GPCRs as well as the quantifying resorption-associated surface molecules highlights the identification of targets and monitors for anti-resorptive treatment options.

Critical role of osteoclast-derived EVs in medication-related osteonecrosis of the jaws (MRONJ) *Sakura Minami[1], Yasuyuki Fujii[1], Ayano Hatori[1], Yusuke Yoshioka[2], Takahiro Ochiya[2], Daichi Chikazu[1]. [1]Department of Oral and Maxillofacial Surgery, Tokyo Medical University, Japan. [2]Department of Molecular and Cellular Medicine, Tokyo Medical University, Japan

Medication-related osteonecrosis of the jaws (MRONJ) is an intractable form of osteonecrosis of the jaw that rarely occurs in patients with malignancies and osteoporosis who are using bone resorption inhibitors such as bisphosphonates (BPs). MRONJ is mainly triggered by surgical invasion such as tooth extraction. However, the detailed mechanism of MRONJ pathogenesis is unknown. Extracellular vesicles (EVs) encode many signaling molecules such as mRNAs, miRNAs, and proteins, and have attracted attention as intercellular communication tools. It has also recently been shown that EVs are also involved in communication between osteoclasts and osteoblasts. The aim of this study is to elucidate the pathomechanism of MRONJ by studying the role of osteoclast-derived EVs . Mouse bone marrow cells were treated with M-CSF and RANKL to induce osteoclastogenesis. Zoledronic acid (ZA) were added to the culture medium to reproduce the MRONJ environment in vitro. EVs were isolated from the culture supernatant by ultracentrifugation and miRNA were extracted from the osteoclast-derived EVs. TRAP staining of the osteoclasts with ZA showed lower osteoclastgenesis. In addition, Phalloidin/Actin staining also showed that ZA significantly decreased osteoclast activity. miRNA Seq analysis identified 11 upregulated and 5 downregulated differentially expressed genes (DEGs) in miRNA of the EVs derived from osteoclasts with ZA. The expression of these DEGs was confirmed by qPCR and miR-146a-5p, and miR-322-3p were upregulated by ZA. An mRNA-seq analysis of the osteoclasts was conducted to identify mRNA target and clarify the molecular and functional mechanism of miRNA of the EVs. Our data demonstrated that BPs attenuate osteoclastgenesis simultaneously changing the characteristics of the osteoclast-derived EVs. We suggest that intercellular communication by the osteoclast-derived EVs may play important roles in the pathogenesis of MRONJ.

The endosomal RANKL-LGR4 signaling during osteoclast differentiation *Wonbong Lim[1], Beomchang Kim[1], Young Jong Ko[1], Yuria Jang[1]. [1]Department of Premedical Science, College of Medicine, Chosun University, Republic of Korea

LGR4 (Leucine-rich repeat-containing G-protein coupled receptor 4, also known as GPR48) is a membrane receptor and known as a negative regulator of RANK signaling cascade during osteoclast differentiation. Although cell signaling and endocytic membrane trafficking from membrane receptor have traditionally been viewed as distinct processes, it is now recognized that these processes are intimately and bidirectionally linked. In this study, we investigated the difference between membrane-bound LGR4 signaling and internalized LGR4, and whether the LGR4 signaling cascade gives RANKL signal in internalized endosomes as an potential regulator during RANKL-induced osteoclastogenesis. Herein, we showed that LGR4 is endocytosed to endosome after binding to RANKL in osteoclast precursor cells RAW 264.7s. The internalized LGR4 activates LGR4-RANKL signaling in the early endosome. When RANKL is bound to LGR4, it is endocytosed and located in the Rab5 positive ealry endosome. In LGR4-down regulated RAW 264.7 cells, it was analyzed that the early endosome signal increased and the inhibitory phosphorylation of GSK-3beta decreased. Raw 264.7 cells treated with Dynasore (Dynamin inhibitor) confirmed the same reduction in inhibitory P-GSK3B as LGR4 CKO(Conditional Knock-out) cells. With similar results, it was confirmed that the reduced inhibitory P-GSK3B was recovered when DRG2 KO mice were treated with Dynasore, which is similar to the results of DRG2 WT mice. As a result of confirming NFATC1 nuclear translocation by RANKL treatment in LGR4 CKO Raw 264.7 cells and DRG2 KO mouse, nuclear translocation of NFATC1 increased in both groups. In addition, decreased bone density and increaesd TRAP activity in DRG2

KO mice which is known to be increased the early endosome duration were investigated. Taken together, our result showed that the internalized LGR4 could be a potential regulator for the modulation of osteoclast differentiation via RANKL-LGR4 signaling in endosomes.

Pharmacological inhibition of protein S-palmitoylation suppresses osteoclastogenesis and ameliorates ovariectomy-induced bone loss *Jianquan Chen[1], Linghui Ma[2], Liwei Zhang[2], Zirui Liao[2], Chunmei Xiu[2]. [1]Hangzhou City University, China. [2]Soochow University, China

Excessive osteoclast formation disrupts bone homeostasis, thereby significantly contributing to pathological bone loss associated with a variety of diseases. Protein S-palmitoylation is a reversible post-translational lipid modification catalyzed by ZDHHC family of palmitoyl acyltransferases, which plays an important role in various physiological and pathological processes. However, its role in osteoclastogenesis remains unexplored. Here, we identified palmitoylation as a novel and critical regulator of osteoclast differentiation. We found that many proteins were palmitoylated in differentiating osteoclasts, whereas pharmacological inhibition of palmitoylation impeded RANKL-induced osteoclastogenesis in vitro, and to a lesser extent, osteoblast formation from MC3T3-E1 cells. Mechanistically, we showed that 2-BP treatment inhibited osteoclastogenesis partly by downregulating the expression of c-Fos and NFATc1 without overtly affecting RANKL-induced activation of osteoclastogenic AKT, MAPK, and NF-?B pathways. Furthermore, we demonstrated that administration of 2-BP protected mice from ovariectomy-induced osteoporosis and bone resorption. Taken together, our study has revealed protein palmitoylation as a key mechanism regulating osteoclast differentiation, thus providing a potential therapeutic target for treating osteolytic bone diseases.

Heparan sulfate selectively inhibits the collagenase activity of Cathepsin K *Xiaoxiao Zhang[1], Yin Luo[1], huanmeng Hao[1], Guowei Su[2], Juno Krahn[3], Miaomiao Li[1], Jian Liu[4], Lars Pedersen[3], Ding Xu[1]. [1]University at Buffalo, United States. [2]Glycan Therapeutics LLC, United States. [3]NIEHS, United States. [4]University of North Carolina, Chapel Hill, United States

Cathepsin K (CtsK) is a cysteine protease with potent collagenase activity. CtsK is highly expressed by bone resorbing osteoclasts and plays an essential role in bone remodeling. Although CtsK is known to bind heparan sulfate (HS) with low nanomolar affinity, it remains unknown how HS might regulate the biological functions of CtsK. Here we report that HS can selectively inhibit the collagenase activity of CtsK without inhibiting its peptidase activity. The inhibitory potency of HS directly correlates with the sulfation levels of HS. By X-ray crystallization study of the CtsK-HS complex we discovered that HS could induce CtsK to form a highly stable tetramer. In this structure the complex adopts a 1:4 (HS:CtsK) stoichiometry, and HS is sandwiched at the tetramer interface, holding two CtsK dimers together. If appears that formation of such an oligomeric complex is the key for inhibiting the collagenase activity of CtsK. Based on the crystal structure, we identified eight basic residues that play essential roles in mediating HS-binding. Mutating three key HS-binding residues together was able to greatly diminish CtsK-HS interaction. Interestingly, the HS-binding deficient CtsK mutant retained its full collagenase and peptidase activity, but its collagenase activity could no longer be inhibited by HS. Combined, our findings suggest that HS, which is present both in bone matrix and on osteoclasts surface, likely functions as a natural regulator of the collagenase activity of CtsK. In addition, due to the selective nature of the inhibition, HS-like molecules can be explored as a novel strategy to inhibits the collagenase activity of CtsK in diseases that involve exaggerated bone resorption.

The transcriptome at single-cell resolution clarifies the diversity of cell populations. Single-cell RNA-seq (scRNA-seq) has already been adopted for giant cells such as osteoclasts (OCs) (Omata, Okada, JBMR plus 2022). Although large OCs could not pass through a fluid-based cell dissociation device because of their diameter, acid-producing mature OCs were captured using conventional scRNA-seq.At ASBMR 2022, we presented intra-single cell sequencing (iSCseq) (Okada, bioRxiv 2022). iSCseq is a combinatorial method of high-resolution confocal imaging, picking of intracellular components, including a single nucleus, using the Single CellomeTM System SS2000 (Yokogawa, Japan), and next-generation sequencing at high resolution for mRNA. Our previous results showed that individual nuclei within the same cell are heterogeneous in terms of gene expression.The next version of iSCseq called i2scseq (interventional and integrative subcellular sequencing) can also collect cytoplasm in a small ordinary cell with a 3um probe and capture the living subcellular transcriptome. The average number of genes per cell detected by a 10um probe is much higher, and one by a 3um is equivalent to traditional fluid-based sequencing.i2scseq was used for the in vitro lineage of cells differentiating into OCs. i2scseq clarified that some small cells, which were not morphologically regarded as OCs, were classified into the final cluster of lineages, and vice versa, that giant OC contain immature nuclei in terms of gene expression. With integrative analysis of i2scseq and fluid-based sequencing datasets using a deep machine learning method, large OCs have embedded components at many stages of differentiation.i2scseq clarified the subcellular heterogeneity of mature OCs at a higher resolution than previous iSCseq. We partially solved the question of why conventional scRNA-seq has captured so-called mature OCs. i2scseq is expected to be a core method in cell biology.

Role of ATP and ADP in osteoclast mechanotransduction *Svetlana Komarova[1,] Chrisanne Dsouza[1,] [1]McGill University, Canada

Introduction: Physical activity is essential for skeletal health. Upon mechanical loading, ATP and ADP are released from stimulated bone cells and act on purinergic P2 receptors of neighbouring cells. Osteocytes and osteoblasts play important roles in bone response to mechanical loading and have been shown to participate in ATP and ADP-mediated signaling. However, the role of osteoclasts in this process is less understood. The goal of this study was to investigate the role of ATP and ADP in the mechanotransduction of osteoclasts.Methods: Single osteoclasts in primary cultures from 10-12-week-old mice were mechanically stimulated by a gentle touch with a micropipette. Changes in cytosolic free calcium [Ca2+]i were analyzed in fura-2 loaded osteoclasts. Treatment with phosphoenolpyruvate and pyruvate kinase converted all ADP in solution to ATP, and treatment with hexokinase converted all ATP to ADP.Results: Mechanical stimulation with a micropipette resulted in an increase in [Ca2+]i in the primary (stimulated) and the secondary (non-stimulated) neighbouring cells. When cultures were treated with suramin, a broad P2 receptor blocker, primary responders had significantly higher [Ca2+]i amplitude and area under the curve, and secondary responders tended to have a higher area under the curve. In cultures treated with A-804598, a specific inhibitor of P2X7 that is not inhibited by suramin, primary responders tended to have lower calcium response parameters, while secondary responses were abolished. Concentration dependences of osteoclast calcium responses to ATP and ADP demonstrated that more osteoclasts responded with an increase in ATP or ADP concentration. In addition, osteoclasts treated with increasing ADP concentrations demonstrated lower percentage of oscillators and increased amplitude of calcium response. Next, we performed osteoclast mechanical stimulation in the presence of phosphoenolpyruvate and pyruvate kinase, which converted all the mechanotransductive signal to ATP or hexokinase, which converted the signal to ADP. Osteoclasts with mild membrane injury (assessed by the fura-2 loss) demonstrated similar calcium responses in ATP and ADP-rich environments. However, when the mechanotransductive signal to severe osteoclast injury was converted to ADP, the fraction of secondary responders and their [Ca2+]i amplitude were higher.Conclusions: ATP and to a higher degree ADP play important roles in osteoclasts-mediated mechanotransduction.

SUN-352

La, a repurposed RNA-binding protein, regulates osteoclast multinucleation and function. *Jarred M. Whitlock[1,] Evgenia Leikina[1,] Kamran Melikov[1,] Luis Fernandez De Castro Diaz[2,] Sandy Mattijssen[1,] Richard Maraia[1,] Michael Collins[2,] Leonid Chernomordik[1,] [1]NICHD, United States, [2]NIDCR, United States

Multinucleated osteoclasts, essential for skeletal remodeling in health and disease, are formed by the fusion of osteoclast precursors, where each fusion event raises their bone-resorbing activity. Here we show that the nuclear RNA chaperone, La protein has an additional function as an osteoclast fusion regulator. Monocyte-to-osteoclast differentiation starts with a drastic decrease in La levels. As fusion begins, La reappears as a low molecular weight species at the osteoclast surface, where it promotes fusion. La's role in promoting osteoclast fusion is independent of canonical La-RNA interactions and involves direct interactions between La and Annexin A5, which anchors La to transiently exposed phosphatidylserine at the surface of fusing osteoclasts. Disappearance of cell-surface La, and the return of full length La to the nuclei of mature, multinucleated osteoclasts, acts as an off switch of their fusion activity. Targeting surface La in a novel explant model of fibrous dysplasia inhibits excessive osteoclast formation characteristic of this disease, highlighting La's potential as a therapeutic target.

The PDE4 inhibitors Roflumilast and Rolipram Rescue ADO2 Osteoclast Resorption Dysfunction *Jung Hong[1,] Angela Bruzzaniti[1,] Rita O'Riley[2,] Dena Acton[2,] Imranul Alam[2,] Michael Econs[2,] [1]Indiana University School of Dentistry, United States, [2]Indiana University School of Medicine, United States

Autosomal Dominant Osteopetrosis type II (ADO2) is a rare bone disease of impaired osteoclastic bone resorption caused by heterozygous missense mutations in the chloride channel 7 (CLCN7). Previous reports have shown that ADO2 knock-in mouse models containing the CLCN7 mutation exhibit elevated bone mass. A CLCN7 mutation is thought to affect not only Clcn7 chloride exchange activity but also affect endosomal-lysosomal trafficking which is critical for formation of the resorption lacunae of active osteoclasts. It is well known that adenylate cyclase is critical for lysosomal acidification in osteoclasts and other cells. Adenylate cyclase catalyze the formation of cyclic adenosine monophosphate (cAMP), an important small second messenger that activates key cellular target proteins. Intracellular cAMP concentration is tightly regulated at the level of its synthesis by adenylate cyclase and hydrolysis by specific phosphodiesterase (PDEs). We investigated the cellular mechanism involved in ADO2 OC dysfunction and found that both immature and mature ADO2 osteoclasts exhibit reduced cAMP levels, compared to wild-type OCs, implicating the signaling pathways that regulate cAMP synthesis or hydrolysis. QPCR analysis revealed higher expression levels of the three PDE4 subtypes (4a, 4b, 4d) in ADO2 osteoclasts compared in WT. Next, we examined the effects of two cAMP specific PDE4 inhibitors, roflumilast and rolipram, on ADO2 osteoclast formation and resorption activity in vitro. Non adherent bone marrow macrophages from ADO2 and WT mice were cultured with RANKL and MCSF in the presence of roflumilast or rolipram (0-250 nM). Roflumilast and rolipram increased osteoclast formation in a dose-dependent manner in both ADO2 and WT osteoclasts. Importantly, the PDE4 inhibitors also displayed a concentration-dependent increase in osteoclast resorption activity which was greater in ADO2 osteoclasts than WT osteoclasts. The key findings from our studies demonstrate that ADO2 mice exhibit reduced cAMP levels and that PDE4 inhibition by rolipram and roflumilast rescue ADO2 osteoclast activity dysfunction in vitro. Further understanding of this mechanism will potentially lead to the development of new approaches for the treatment of clinically affected ADO2 patients.

Proton-Activated Chloride Channel Enhances Endplate Porous Osteoclast Resorption to Induce Spinal Pain *Weixin Zhang[1,] Peng Xue[2,] Shenyu Wang[2,] Jiachen Chu[2,] Janet Crane[2,] Mei Wan[2,] Zhaozhu Qiu[2,] Xu Cao[2,] [1]Johns Hopkins university, , [2]Johns Hopkins University, United States

Proton-activated chloride (PAC) channel is responsive to pathological acidic pH in ischemic brain injury in mice and acid-induced neuronal cell death as a completely new ion channel family. Our PAC structure study revealed that the protein exists in two states: namely, a high-pH resting closed state and a low-pH proton-bound non-conducting state. PAC channel undergoes striking conformational changes when the pH drops from 8 to 4, leading to an opening of the channel and the conduction of anions across cellular membranes, thereby inducing diseases associated with tissue acidosis (acid-induced cell death). Skeletal pain in bone disorders is often associated with aberrant osteoclast-mediated resorption due to very low pH environments. But the role of PAC in pathological osteoclast resorption and spinal pain is still unexplored. Chronic low back pain (LBP) can severely affect daily physical activity and is one of the leading risk factors for the development of immobility and frailty. Aberrant osteoclast-mediated resorption during spinal degeneration leads to the development of a porous endplate that in turn allows for the sensory innervation of the spinal unit, leading to LBP. But the mechanism by which aberrant osteoclast activity occurs during spinal degeneration is unclear. Here, we report that the expression of proton-activated

chloride channel (PAC) is induced specifically in the apical membrane of osteoclasts in the porous endplates via a RANKL-NFATc1 signaling pathway. Extracellular acidosis evokes the ICl, H current in the cell membrane of osteoclasts by activating the PAC-encoded Cl? channel. Thus, a combination of an acidic environment of porous endplates and elevated PAC expression results in enhanced osteoclast fusion and resorption that, in turn, provokes LBP. Further, we find that genetic knockout of PAC significantly reduces endplate porosity and spinal pain in a mouse model of spine degeneration, but it does not affect bone development or homeostasis of bone mass in adult mice. Aberrant osteoclast-mediated resorption is found in most skeletal disorders, including osteoarthritis, ankylosing spondylitis, rheumatoid arthritis, heterotopic ossification, enthesopathy, and Paget disease, in addition to spine degeneration. Thus, elevated PAC expression and PAC activity could be a common mechanism for various bone pathologies and thus a potential therapeutic target.

Single Cell Transcriptomic Analysis of Adult Murine Long Bone Reveals a Novel Epcam+ Osteocyte-like Subpopulation *Cesar Morfin[3], Gabriela Loots[2], Aimy Sebastian[3], Nicholas Hum[4], Stephen Wilson[3], Deepa Murugesh[3]. [3]Lawrence Livermore National Laboratory, [2]University of California, Davis, United States, [3]Lawrence Livermore National Laboratory, United States, [4]Lawerence Livermore National Laboratory, United States

The skeleton mediates several diverse functions; in addition to providing mobility, structural and mechanical support it also is a reservoir for blood cell production, mineral storage, and endocrine regulation. While osteoblasts (OB) and osteoclasts are two major cell types that drive remodeling, osteocytes (OCY) make up 95% of all cells in the mineralized bone and are considered the 'master orchestrator'. Current experimental approaches to isolate primary bone cell populations have been hampered by an inability to identify, isolate and study specific subpopulations of bone cells due to the heterogeneity of populations of the MSC lineage. Currently, the differentiation trajectory of bone cells is not clear and is further complicated by the transdifferentiation and plasticity now recognized to occur between cell types of the osteogenic lineage. Single cell RNA (scRNA-seq) technologies can help better define the underlying osteogenic lineages by highlighting specific subpopulations. Previously, Yoshioka et al found several osteoblast subpopulations that were isolated from newborn mouse calvaria which were representative of different maturational stages. In the current study, we isolated primary bone cell populations for scRNA-seq from unlabeled and fluorescently labeled cells (Dmp1-Cre; Ai9 and Bglap-Cre; Ai9) mice to further understand the unique transcriptional signatures, developmental trajectories, and potential novel functions bone cells captured from murine long bones may have. Based on transcriptional signatures, most bone cell populations were captured that include mesenchymal/fibroblast progenitors (MP/FP), osteoprogenitors (OP), pre-osteoblasts (pOB), osteoblasts (OB), osteo-chondro progenitors (OCP), chondrocytes (CH), OCYs, and OB/OCYs. The isolation methods also captured adipo-progenitor populations that also expressed various Wnt, and Bmp1 regulators as well as pro-bone cytokines. Focusing on Sost and Dmp1-expressing OCY subpopulations, we found a population with robust expression of several genes including Epcam, Ndrg1, Prr15, Ramp1 and Pdgfa that have not been previously described in osteocytes. Immunohistochemistry of Epcam in long bones highlighted a population embedded in bone beneath the articular cartilage that is strongly expressing this protein. Further study of these Epcam+ bone cells could provide insights into a previously undescribed OCY-like subpopulation that could be mediating a novel function. Such knowledge could lead towards identifying additional bone cell subpopulations involved in modulating bone metabolism that may open new opportunity for promoting bone formation.Work was conducted under the auspices of the USDOE by LLNL (DE-AC52-07NA27344).

Identification of RNA localization elements controlling mRNA transcript enrichment in osteocyte dendrites *Courtney Mazur[1], Christian Castro Andrade[2], Parthena Kotsalidis[2], J. Matthew Taliaferro[3], Marc Wein[1]. [1]Massachusetts General Hospital, [2]MASSACHUSETTS GENERAL HOSPITAL, United States, [3]University of Colorado School of Medicine, United States

Subcellular compartments like neuronal dendrites and fibroblast protrusions contain local transcriptomes that contribute to morphology and function. Trafficking of mRNA within cells is controlled by RNA binding proteins that recognize localization sequences in mRNA, often found in the 3' untranslated region (3'UTR). Our subcellular transcriptomic analysis identified 420 mRNA transcripts enriched in dendrites of osteocyte-like Ocy454 cells compared to cell bodies (log2FC>=1, padj<0.01). These transcripts largely encode for ribosomal proteins, electron transport chain, and cytoskeletal proteins. To learn how osteocytes traffic these specific mRNAs to dendrites, we tested the hypothesis that osteocyte dendrite-enriched transcripts contain localization sequences in their 3'UTRs. We used a heterologous reporter system in which the 3'UTR of one dendrite-enriched mRNA was cloned downstream of the Firefly luciferase (FLuc) coding sequence. Untagged Renilla luciferase (RLuc) served as a control. Ocy454 cells stably expressing one 3'UTR reporter were grown on transwell membranes with 1 ?m pores to facilitate fractionation of dendrites from cell bodies. Relative expression of FLuc mRNA to RLuc mRNA was measured by RT-qPCR in dendrites and cell bodies. For Palld, Fgd3, and 9 of 13 other dendrite-enriched transcripts tested, the 3'UTR was sufficient to promote dendrite localization of FLuc, whereas the 3'UTR of cell body-enriched Pth1r mRNA did not cause dendrite localization. We then cloned 500-1000 nucleotide (nt)-long fragments of the Palld and Fgd3 3'UTRs into our reporter (full lengths 1919 and 2230 nt, respectively). In each case, one fragment caused maximal dendrite localization, indicating that the localization sequence is contained within that region of the 3'UTR. To precisely identify localization sequences, we are performing a massively parallel reporter assay with 260 nt-long sequences tiled at 4 nt intervals across these 11 dendrite-targeting 3'UTRs. To learn why osteocytes localize certain transcripts to dendrites, we investigated the role of Palld on osteocyte morphology. CRISPR-mediated Palld knockout in Ocy454 cells causes a 5-fold reduction in dendrite length and a 2-fold reduction in branching ($p<0.01$). Together our data suggests that dendrite-localized mRNA contributes to osteocyte morphology and is often trafficked via sequences in the 3'UTR. This molecular regulatory mechanism may be a future therapeutic target for osteocyte and bone disorders.

Effect of DAMPs Released from Osteocyte Necroptosis on Osteoclastogenesis *Fumitoshi Ohori[1], Hideki Kitaura[2], Takahiro Noguchi[1], Aseel Marahleh[2], Jinghan Ma[1], Kayoko Kanou[1], Mariko Miura[1], Jiayi Ren[1], KOHEI NARITA[1], Itaru Mizoguchi[1]. [1]Tohoku University Graduate School of Dentistry, Japan, [2]Tohoku University, Japan

Necroptosis is a form of regulated cell death that can be triggered by tumor necrosis factor-? (TNF-?) and is related to the activation of receptor-interacting protein 3 (RIP3) and mixed lineage kinase domain-like protein (MLKL). Necroptosis ruptures the plasma membrane leading to the release of damage-associated molecular patterns (DAMPs). During orthodontic tooth movement (OTM), TNF-? expression and osteocyte death have been demonstrated on the compression side. Additionally, osteocytes have been shown to induce osteoclast formation; however, there has been no report regarding the role of osteocyte necroptosis in osteoclastogenesis during OTM. The purpose of this study is to investigate the effect of osteocyte necroptosis on osteoclastogenesis during OTM. As an OTM model, a Ni-Ti closed-coil spring was attached to move the first molar to the mesial direction in eight-week-old male C57BL/6J mice. Histological sections were stained for tartrate-resistant acid phosphatase (TRAP), and osteoclast numbers were determined. To investigate osteocyte necroptosis in OTM, Hematoxylin and Eosin (H&E) staining and immunofluorescence staining were performed. On day 6 of OTM, a large number of osteoclasts appeared on the compression side. H&E staining revealed that necrotic osteocytes also increased on day 6. Furthermore, RIP3 was detected in osteocytes on day 6 with immunofluorescence staining. To obtain high-purity primary osteocytes, Topaz-positive osteocytes were isolated by fluorescence-activated cell sorting (FACS) from Dmp1-Topaz mice whose osteocytes express the green fluorescent protein. Necroptosis was induced by stimulating primary osteocytes with TNF-?, SM-164, and zVAD (TSZ). Necroptosis of osteocytes were detected by immunofluorescence staining. To assess the effect of DAMPs on osteoclastogenesis, bone marrow macrophages derived from bone marrow cells of TNF receptors deficient mice were treated with RANKL and conditioned medium from osteocyte necroptosis. RIP3 and MLKL activation in primary osteocytes was observed 4 and 6 hours after TSZ stimulation, respectively. Although the conditioned medium from viable osteocytes did not affect osteoclastogenesis, the conditioned medium from necroptotic osteocytes significantly enhanced osteoclastogenesis. In conclusion, these results suggest that osteoclastogenesis on the compression side during OTM is enhanced by DAMPs released from osteocytes necroptosis.

Live Cell, Confocal and Tissue Clearing/3D Imaging in Mice Expressing a Membrane-GFP targeted to Osteocytes, Odontoblasts and Cementocytes *Yixia Xie[1], David Moore[1], Eleanor Ray[1], Lisa Le[1], Sarah Dallas[1]. [1]University of Missouri - Kansas City, United States

High resolution 3D imaging of cells in hard tissues is challenging due to the light scattering properties of mineralized matrix. Resolving fine detail of osteocyte, cementocyte & odontoblast dendritic processes requires cell-specific staining methods targeting the membrane or specific substructures in the dendrites. Using transgenic mice expressing a membrane-bound GFP driven by the 10kb Dmp1 promoter (Dmp1-mGFP mice) or mice co-expressing Dmp1-mGFP & a LysM-Cre/tdTomato reporter to target osteoclasts, we have used 3D confocal imaging & tissue clearing/3D imaging to define tissue localization of the mGFP reporter and fine cellular detail of osteocytes, odontoblasts & cementocytes in the lower jaw. Samples were counterstained with alexa555-phalloidin to visualize F-actin and DAPI to label nuclei. Dmp1-mGFP mice were also used for confocal live cell imaging to examine osteocyte embedding dynamics. 3D confocal imaging on 50?m cryosections in 7d mandibles showed Dmp1-mGFP expression in osteocytes, odontoblasts, pulpal cells adjacent to odontoblasts and a subset of mature osteoblasts. Membrane-targeting of GFP enabled resolution of branching & fine detail of odontoblast processes (Fig.1) and osteocyte dendrites. Dmp1-mGFP was also expressed in cementocytes in 2mo mice. Dmp1-mGFP also labeled 80-500nm extracellular vesicle-like particles, at the dentin-enamel junction adjacent to odontoblast processes (Fig 1, arrows) and throughout the mineralized bone & cementum matrix, which likely represent matrix vesicles that initiate mineralization. PEGASOS

clearing enabled deep tissue imaging and lightsheet imaging enabled 3D reconstruction of Dmp1-mGFP & LysM-Cre/td tomato expression in the intact mandible and virtual sectioning in any plane. This also revealed Dmp1-GFP expression in a subset of cells in blood vessels supplying the cervical loop region of the incisor. Long term live cell imaging of osteocyte embedding in calvarial explant cultures revealed Dmp1-mGFP first switching on in post mitotic polygonal cells that extended and retracted dendrites during embedding/positioning. Live imaging of osteoclasts & osteocytes revealed that the majority (95%) of osteocytes die during the process of bone resorption. We conclude that the Dmp1-mGFP mouse is a valuable tool for studying differentiation of mineralizing cell types and imaging their fine structure and is compatible with high resolution confocal imaging, tissue clearing/3D lightsheet imaging & live cell imaging.

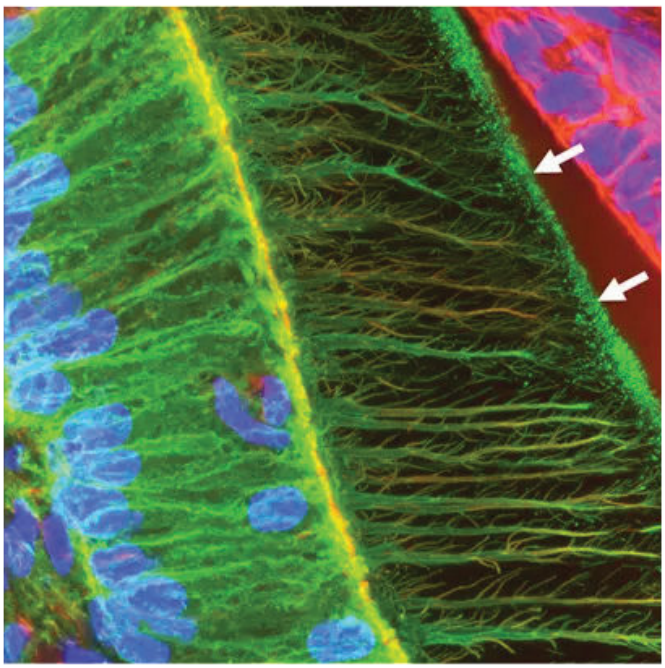

Fig. 1: Dmp1-mGFP expression in odontoblasts showing fine detail of odontoblast processes and GFP positive vesicles close to the dentin- enamel junction (arrows). (green – Dmp1-mGFP, blue = nuclei; red = F-actin)

Regulation of Lipid Droplet Formation in Osteocytes Under Physiological and Pathological Conditions *MATHILDE PALMIER[1], Yukiko Kitase[2], Lynda Bonewald[3], Matt Prideaux[4]. [1]Inserm, France. [2]Indiana University, School of Medicine, United States. [3]Indiana University School of Medicine, United States. [4]Indiana University, United States

Osteocytes are key regulators of bone formation and resorption. We previously found that fatty acids (FAs) are an important source of energy for osteocyte metabolism through ?-oxidation, but this process is impaired in aged bone. Osteocytes accumulate FAs in the form of lipid droplets (LDs) under pathological conditions such as alcohol or steroid excess. However, questions remain whether osteocytes form LDs under physiological conditions and whether excessive LD accumulation occurs with aging and associated co-morbidities such as obesity and a sedentary lifestyle.To address this, we are investigating LD formation under both physiological and pathological conditions. For physiological in vitro experiments, MLO-Y4 and IDG-SW3 cell lines were treated with BSA-complexed oleic acid (OA) for 24 hrs with the addition of L-carnitine to promote ?-oxidation. 100-250 ?M OA significantly increased expression of the key ?-oxidation regulator Cpt1a and LD-droplet associated gene Plin2 in MLO-Y4 and IDG-SW3 cells. Sost mRNA expression was significantly decreased by OA treatment in IDG-SW3 cells, but there was no change in Tnfsf11/Tnfrsf11b (Rankl/Opg) in either MLO-Y4 or IDG-SW3 cells. This suggests a potential beneficial effect of OA and LDs in young, healthy osteocytes through increased ?-oxidation.To understand the role of LDs in pathological conditions, MLO-Y4 cells were cultured with 100 ?M OA and the CPT1 inhibitor etomoxir to block ?-oxidation. This significantly increased LD accumulation and Plin2 mRNA expression compared to control MLO-Y4 cells, suggesting that impaired ?-oxidation leads to lipid dysregulation in osteocytes. Seahorse ATP rate assay also showed that IDG-SW3 osteocyte energy metabolism was primarily oxidative and that blocking ?-oxidation decreased both mitochondrial and overall ATP production rates. To examine LDs in osteocytes in vivo, obese 18 month female C57Bl/6 mice were fed a high fat diet (HFD) for 5 months. LDs were detected in sections of femoral osteocytes (Figure 1), suggesting a potential link between dietary fat intake, aging, and osteocyte lipid accumulation.Ongoing studies will determine whether exercise of HFD-fed mice reduces LD burden through mechanical strain induced ?-oxidation in osteocytes and if excess LD accumulation in aged osteocytes is a driver of impaired bone health in aging.

Bone formation by osteoid-osteocytes and osteocytes in C57Bl/6 mice *Sarah Ford[1], Svetlana Komarova[2], Katharina Jähn-Rickert[3], Kerstin Tiedemann[2], Elizabeth Zimmermann[2, 1], . [2]McGill University, Canada. [3]University Medical Center Hamburg-Eppendorf, Germany

Purpose: Bone formation is described as occurring on bone surfaces by osteoblasts. However, as bone forming osteoblasts become entrapped in the bone matrix, these so-called osteoid-osteocytes may continue to produce bone matrix while differentiating into osteocytes [1]. Mature osteocytes deeply embedded in the bone have also been observed to remodel their surrounding bone matrix in lactation and hibernation: a process termed perilacunar remodeling [2]. The contribution of osteocyte-driven bone remodeling in the regulation of healthy bone tissue is currently unknown.Methods: Skeletally mature female C57Bl/6 mice received two calcein injections. MMA-embedded undecalcified L3-L5 vertebrae sections were prepared. A region of interest (ROI) of trabecular bone was identified and the bone area of the ROI was measured on brightfield images. Osteocyte lacunae with calcein labels were identified on z-stacks imaged with confocal microscopy. Lacunae were classified (Fig. 1) as osteoid-osteocytes (in or adjacent to the line of osteoblast bone formation) or mature osteocytes (> 3 µm from osteoblast bone formation labels). Bone formation rate (BFR) due to osteoblast activity on bone surfaces followed ASBMR guidelines. BFR of mature osteocytes was measured as follows:BFRosteocyte=(L.Th)/(Ir.L.t) ((sLSocy)/(Ocy.S)) L.Th is label thickness, Ir.L.t is time between calcein injections, and sLSocy is lacunar label length. Ocy.S is total osteocyte surface calculated as the product of lacunar density, bone area and average lacunar perimeter.Results: Active bone formation was observed in 206 +/- 64 lacunae/mm2. Around 80-90% of labeled lacunae were associated with bone forming osteoid-osteocytes (173 +/- 50 lacunae/mm2) and 16% mature osteocytes (33 +/- 6 lacunae/mm2). The osteoblast BFR was 3.17 µm/day and the osteocyte BFR was 0.078 nm/day (not including osteoid osteocytes).Conclusion: Here, we observed that a majority of bone formation at lacunae occurs at osteoid-osteocytes, which should be distinguished from mature osteocytes. BFR due to osteocyte activity may seem small, but perilacunar remodeling is an emerging phenomenon for which the implications on bone quality and bone fragility are not fully understood.References:1. Is osteocyte function impaired in Jansen disease? *Renata C Pereira[1], Thomas J Gardella[2], Barbara Gales[3], Monica Reyes[4], Harald Juppner[2], Isidro Salusky[5]. [1]Pediatric Nephrology, UCLA, Geffen School of Medicine, United States. [2]Endocrine Unit and Pediatric Nephrology Unit, Massachusetts General Hospital and Harvard Medical School, , United States. [3]Pediatric Nephrology, UCLA, Geffen School of Medicine, , United States. [4]Endocrine Unit, Massachusetts Hospital and harvard Medical School, United States. [5]University of California, Los Angeles School of Medicine, United States

Jansen metaphyseal chondrodysplasia (JMC) is an ultra-rare autosomal dominant disease caused by heterozygous, activating PTH/PTHrP receptor (PTH1R) mutations. Patients display short stature, long bone bowing, craniofacial abnormalities, and growth plate abnormalities that resemble severe rachitic changes. They also exhibit hypercalcemia and hypercalciuria leading to nephrocalcinosis and risk of impaired renal function. Five different PTH1R mutations affecting one of three different amino acids (H223R, T410P/R, and I458K/R) are known to cause JMC. The mutant PTH1R in the growth plates is predicted to slow rates of chondrocyte maturation and hence lead to reduced chondrocyte hypertrophy and reduced formation of primary spongiosa and bone tissue. However, there is currently little known about how the mutant receptors impact processes of bone formation and bone turnover, particularly in young JMC patients. In the current study, we assessed histologically the bone phenotype in two brothers (6 and 8 years old) with JMC (H223R mutation). Serum and urine markers of bone and mineral ion metabolism were also evaluated in both pts:1,25D: 82, 70 pg/ml; PTH: <2.5 pg/ml for both; ALP: 632, 564 IU/L; FGF23: 110, 98 RU/ml; Ca: 10.6, 10.5 mg/dL; P: 3.2, 3.5 mg/dL. Urine NTX: 1757, 1212 (167-578 nM BCE/mM Creatinine). Histomorphometric analyses of dual tetracycline labels in iliac crest biopsies revealed, as compared to age-matched controls, decreased trabecular bone formation, increased mineralization lag time and delayed?? osteoid maturation; reduced connectivity between trabecular plates; decreased cortical thickness consistent with lower turnover osteopenia, and persistent cartilaginous remnants. Bone marrow fibrosis was also detected close to endocortical areas. Immunohistochemical analyses revealed increased osteocytic bone staining for both FGF23 and DMP1 without co-localization and decreased staining for sclerostin. Staining for PTH1R was increased in trabecular bone close to lining cells or cell surface progenitors. Photon silver staining demonstrated osteocyte perilacunar/canalicular abnormalities, including decreased numbers and lengths of dendrites, and osteoid halos, and large lacunae; these findings are similar to those seen with PHEX and SP7 mutations (Fig.1). These intriguing observations suggest that activating PTH1R mutations impair not only maturation of growth plate chondrocytes, the activity of osteoblasts and osteoclasts, but also of osteocyte biology.

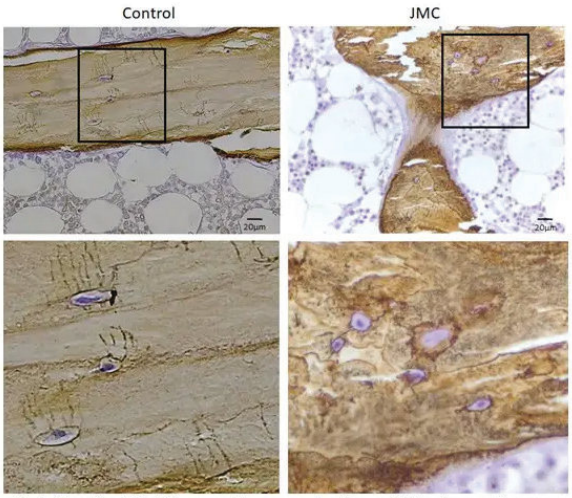

Fig.1: Non-decalcified iliac crest biopsy samples from a JMC patient and an age-matched control were photon silver-stained to assess osteocyte morphology.

Investigating Osteocyte Morphology in Crtap -/- Mouse Model of Recessive Osteogenesis Imperfecta *Carolina Leynes[1], Ellen Busschers[1], Mary Adeyeye[1], Iwen Song[1], Yangjin Bae[1], Brendan Lee[1]. [1]Baylor College of Medicine, United States

Osteogenesis Imperfecta (OI) is characterized by short stature and brittle bones. OI type VII has been associated with the loss of CRTAP (Cartilage-associated protein) which is responsible for post-translational modifications of type I collagen via 3-hydroxylation of Pro986 of chain alpha1(I) and Pro707 of chain alpha2(I). Currently, Crtap-/- mice are used as a model for recessive OI as mice present with a decrease in body size, osteo-chondrodysplasia, kyphosis, and severe osteopenia. Furthermore, our lab and others have shown Crtap-/- mice have upregulated transforming growth factor-? (TGF-?) resulting in decreased bone volume to total bone volume (BV/TV), maximum load, and ultimate strength. In addition, an increase in osteoclast, osteoblast, and osteocyte was observed in Crtap-/- mice. Previous studies in children with OI type I and V have also shown an increase in osteocyte number in cortical and trabecular bone compared to age match controls. Given osteocytes' mechanosensory and bone regulatory role via sclerostin and RANKL secretion, we studied morphological changes in osteocytes of Crtap-/- mice. In this study, we collected femurs from Crtap-/- and WT mice of 4 months of age (n=6) and performed phalloidin staining on 30 ?m sections. Using Imaris analysis software, we processed the images and analyzed osteocyte dendrite length, branch depth, branch level, and area. Our analysis showed an increase osteocyte number, consistent with our and others' previous report, and a decrease in dendrite branch length, depth, level, and area in Crtap-/- mice compared to WT control mice. Our data suggest Crtap-/- mice have decrease osteocyte branching complexity which might be correlated to the decrease in bone mass, maximum load, and ultimate strength previously published by our group. Future studies will further determine the changes in dendrite network after 1D11, an anti-TGF-? treatment, in Crtap-/- mice and investigate the underlying molecular changes in osteocytes of OI models such as Crtap-/- mice and additional OI mouse models.

Exposure to disuse sensitizes osteocytes to the formation of plasma membrane disruptions (PMD) upon reloading *Anik Tuladhar[1], Wesley McGee[1], Luke Horne[1], Joseph Shaver[1], Mark W. Hamrick[1], Meghan McGee-Lawrence[2]. [1]Augusta University, United States. [2]Medical College of Georgia, Augusta University, United States

Disuse (such as during spaceflight) leads to loss of bone mass and strength. Astronauts can lose approximately 1% to 1.5% of their bone mineral density per month while in space, making it crucial to develop better strategies to maintain bone health during and after spaceflight when returning to gravitational forces. Recently, we and others have reported that osteocytes develop transient, survivable plasma membrane disruptions (PMD) during application of high-impact mechanical loading that allows them to sense and respond to this loading via initiation of mechanotransduction cascades. In the current study, we hypothesized that osteocyte PMD formation may play a role in the sensation and response to normal gravitational loads. To test this, we employed a rotary cell culture system (RCCS) to simulate a microgravity environment and tested whether osteocytes subjected to microgravity demonstrate altered PMD formation upon reloading. Differentiated OCY454 osteocyte-like

cells were grown in 3D collagen coated scaffolds (Alvetex) for 7 days followed by culture in the RCCS system for 3 days. Gene expression analyses (RT qPCR) revealed that 3 days of disuse via RCCS culture up-regulated mRNA expression of Sost by 30 fold as compared to static controls, validating previously reported effects of disuse from RCCS in this cell line. A subset of cell-seeded scaffolds were subjected to reloading via turbulent fluid shear stress (TFSS) (n=5 biological replicates) in the presence of fluorescent dextran (10 kDa) in the culture media which acts as a PMD tracer. Reloading following culture in microgravity conditions induced the formation of significantly more PMD (+17%) as compared the abundance of PMD formed from TFSS in static controls, suggesting that the cells exposed to microgravity became sensitized to PMD formation upon high-impact reloading. In ongoing studies, we are investigating whether exposure to disuse conditions alters PMD-induced mechanotransduction, PMD repair processes, or mechanisms of post-wounding cell survival downstream of the PMD event.

Irisin modulates murine osteocytic osteolysis in a sex and age-specific manner *Anika Shimonty[1], Fabrizio Pin[1], Matt Prideaux[1], Gang Peng[1], Lynda Bonewald[1]. [1]Indiana University School of Medicine, United States

Irisin, a hormone generated by the proteolytic cleavage of Fibronectin type III Domain Containing protein 5 (FNDC5) has been described to have beneficial effects on the brain and fat, but effects on bone are contradictory [1], as some studies have found positive effects but our studies have shown that irisin deletion protects against bone loss due to ovariectomy [3]. Recently we have shown that irisin deletion also protects against bone loss with lactation and a low calcium (Ca) diet in females but exacerbates male mice bone loss due to a low Ca diet. To determine if irisin plays a role in bone loss with aging, 5 and 20-month (mo)-old mice were compared. No differences were observed between WT and FNDC5 global KO female mice (BV/TV; 57.5% WT:58.5% KO), however, male KO mice, 5 and 20 mo, had higher BV/TV (60.8% KO:57.6% WT) but less biomechanical strength compared to WT males (ultimate force; 18.5N KO:22.1N WT, stiffness;78.6Nmm KO:94.3Nmm WT). With a low Ca diet, both 5 and 18 mo female KO were partially protected against bone loss and weakness: (BV/TV;43.2% KO:40.4% WT), ultimate force (17.8N KO:15.7N WT) and stiffness (59.8Nmm KO:43.4 Nmm WT). In contrast, both 5 and 18-mo male KO mice lost more bone and had lower bone volume (BV/TV; 48.6% KO:55.4% WT) on a low Ca diet and lower ultimate force (14.9N KO:18.4N WT). To begin to identify responsible molecular mechanisms, RNAseq was performed on osteocyte-enriched bone from 5 mo old animals as two major functions of the osteocyte are to remove their perilacunar matrix to provide calcium and to produce RANKL to activate osteoclasts. Sex differences showed that the female WT osteocyte transcriptome had higher expression of genes responsible for osteocytic osteolysis including Acp5, Ocstamp, Dcstamp, Ctsk, Tnfsf11, and Mmp13 compared to WT males. This difference was not evident in KO females compared to KO males. On a low Ca diet, KO females had lower expression of osteocytic osteolysis genes such as Tnsfs11 and Ocstamp compared to WT females. Analysis of the osteocyte transcriptome is ongoing. In summary, in young females irisin aids or primes the osteocyte to release Ca under Ca-demanding conditions to possibly aid in offspring survival, however in the aging female, this effect of irisin on osteocyte function becomes detrimental with sex hormone and/or Ca deficiency. In contrast, irisin appears beneficial for males at any age, but especially with aging.1.Maak et al, Endocr Rev, 20212. Kim et al, Cell, 2018

Vitamin D Receptor Agonist Eldecalcitol Prevents Aging Postmenopausal Osteoporosis by Inhibiting Ferroptosis and Apoptosis of Senescent Osteocytes *Yan Zhang[1], Zheng Ke[2], Shuang-shuang Dong[2], Chun-zhu Gong[1]. [1]Shenzhen Pingle Orthopaedic Hospital, China. [2]Chugai Pharma China Co., Ltd, China

Active vitamin D analog eldecalcitol is clinically applied in treatment of postmenopausal osteoporosis. This study aims to determine the role of eldecalcitol in protection of osteocytes from senescence and the underlying mechanism. The MLO-Y4 osteocytes were exposed to D-gal, one classical inducer of senescence. The ovariectomized (OVX) mice with D-gal treatment were intraperitoneally injected with eldecalcitol. Eldecalcitol reversed senescent phenotypes of MLO-Y4 cells by improving cell morphology and density, decreasing accumulation of ?-gal-positive cells, and down-regulating expression of P16, P21, and P53. Treatments with Z-VAD-FMK or ferrostatin-1 could recover viability of D-gal-treated MLO-Y4 cells. Flow cytometry showed the reduction in percentage of apoptotic cells after eldecalcitol treatment, which enhanced the expression ratio of Bcl-2/Bax. Eldecalcitol reduced cellular ROS and MDA productions, elevated JC-1 aggregates, and up-regulated expression of Nrf2 and GPX4. Eldecalcitol exhibited osteopreserve effects without changes in serum levels of calcium and phosphorus of aging OVX mice. The confocal imaging displayed that eldecalcitol improved osteocytic network organization. The analysis by transmission electron microscopy showed that the ablation of vitamin D receptor led to a reduction in amounts of osteocytes and dendrites in cortical bone. Eldecalcitol decreased senescent osteocytes in tibial diaphysis by SADS assay, attenuated mRNA expression of SASP factors and down-regulated protein expression of senescence-related factors and caspase-3 in osteocytes-enriched bone tissue fraction. The treatment of aging OVX mice with eldecalcitol restored levels of ferroptotic biomarkers in osteocytic fraction. Furthermore, it reduced 4-HNE expression, stimulated Nrf2-positive staining, and promoted nuclear translocation of Nrf2 in osteocytes. The present study revealed the ameliorative effects of vitamin D analog eldecalcitol on apoptosis and ferroptosis of senescent osteocytes, potentially contributing to its protection against aging postmenopausal osteoporosis.

F-Actin Bundles and Cross-linkers in Osteocyte Dendrites *Rosa Guerra[1], Megan Coffin[1], Shannon Modla[1], Velia Fowler[1], Liyun Wang[1]. [1]University of Delaware, United States

Introduction: Osteocytes are the master orchestrators of bone remodeling, and their extensive dendrite network enables them to sense the external mechanical signals and communication with other cells.1,2 With aging, the dendrites deteriorate with bone quality declined.3 Similar to epithelial microvilli and inner ear stereocilia4, osteocyte dendrites are thought to contain rigid tightly packed cross-linked F-actin bundles as in previous mechanosensing models.5 However, the dendrite cytoskeleton details have not been revealed experimentally due to their entombment in a mineralized bone matrix and the high resolution needed to resolve the F-actin fibers (5-7 nm diameter). The goal of this study is to optimize protocols for high-resolution STED imaging and transmission electron microscopy (TEM) of the dendrite cytoskeleton of cultured osteocytes.Methods: MLO-Y4 cells were seeded at a density of 4,000 cells/cm2 onto collagen-coated coverglass and cultured in alpha-MEM with 2.5% fetal bovine serum and 2.5% calf serum for 2-4 days. The F-actin cytoskeleton and selected cross-linkers were stained with SiR-Actin (in live cells), phalloidin and fimbrin and actinin antibodies (in 4% paraformaldehyde fixed cells), followed with STED (pixel ~16.5 nm) and confocal imaging (pixel ~100-200 nm). Additional TEM images (pixel ~0.55 nm) were also taken of cells on coverslips, fixed with 1% osmium tetroxide and 1% glutaraldehyde with an overnight 0.5% uranyl acetate staining and embedding in resin.Results/Conclusions: In cultured osteocytes, there were a few long cellular protrusions containing linear or curved F-actin fibers in a semi-parallel fashion. These fibers were neither located at the center (under confocal) nor formed compact bundles (observed under STED and TEM). Under STED (Fig. 1), fimbrin and actinin were found along the F-actin fibers and they were not fully co-localized with F-actin fibers in the dendrites as suggested in a previous study.6 Overall, the F-actin cytoskeleton of 2D cultured osteocytes is arranged differently than the previous linear actin core model. To understand osteocyte dendrites in vivo, better models are needed.References: (1) Schaffler, Calcif Tissue Int, 2014 (2) Bonewald, JBMR, 2011 (3) Tiede-Lewis, AGING, 2017 (4) Pelaseyed, J Cell Sci, 2018 (5) Wang, PNAS, 2007 (6) Murshid, J Bone Miner Metab, 2007

Sex Differences in in vivo Osteocyte Ca2+ Signaling and Gap Junction Inhibition *JAMES BOORMAN-PADGETT[1], Randy Valcourt[2], Bridget Saw[3], Jelena Basta-Pljakic[2], Mia Thi[4], David Spray[3], Mitchell Schaffler[5, 1], United States. [2]City College of New York, United States. [3]Albert Einstein College of Medicine, United States. [4]ALBERT EINSTEIN COLLEGE OF MEDICINE, United States. [5]The City College of New York, United States

INTRODUCTION: Osteocytes (Ot) in vivo exhibit a highly coordinated Ca2+ signaling response to mechanical loading, in which number of responding Ot increases in proportion to increasing applied strain [1,2]. Earlier studies established this signaling pattern in female mice. Whether Ot in males respond similarly to loading is unknown. Here, we compared

Ot Ca2+ signaling responses to loading in male vs female mice and further tested whether signaling in both sexes responded similarly to gap junction inhibition.METHODS: Osteocyte Ca2+ signaling responses to mechanical loading were examined in tamoxifen inducible GCaMP6f Ca2+ indicator mice (4 mo, n=22F/30M). Studies used urethane anesthesia, which unlike isoflurane does not interfere with gap junctions [3]. This allowed us to test gap junction function using the inhibitor carbenoxolone (CBX). 3rd metatarsals (MT3s) were cyclically loaded to test strains of 250-3000 ??; 2-photon microscopy was used to image Ca2+ fluorescence in diaphyseal Ot during loading [1,2]. CBX was given after the first (baseline) loading bout and 20 minutes were allowed for diffusion into the bone; loading and imaging studies were then repeated. Cumulative in vivo fluorescent signal intensity as a function of time was calculated for each osteocyte in the region of interest (>1000 cells/group). Ot Cx43 gene and protein expression were determined.RESULTS: Ot in male mice showed ~40% greater cumulative fluorescent signal intensity with loading than Ot in female mice [Fig 1A] and occurred at all strain levels. Blocking gap junctions slightly reduced cumulative signal intensity in males. In contrast, blocking gap junctions in females dramatically attenuated Ca2+ signal intensity. Cx43 mRNA and protein levels were significantly higher in male than female Ot [Fig 1B, 1C - mRNA: 1.4-fold; Protein: ~2.5-fold].DISCUSSION: Our studies reveal unexpected differences in loading-induced osteocyte Ca2+ signaling in male and female mice. The reasons underlying this sex difference in Ot response to loading remain obscure, but may include sex hormones effects and/or intrinsic biological differences between males and female cells [4,5]. Indeed, the more profound Ot response to gap junction inhibition in female mice may reflect such a biological difference, as female Ot express comparatively less Cx43 at both gene and protein levels.REFERENCES:1)Lewis+ PNAS 2017 2)Lewis+ JoVE 2023 3)Burt+ Cir Res 1989 4)Lewis+ Bone 2021 5)McNamara+ Curr Ost Rep 2021

Disparate impact of osteocyte oxygen-sensing mechanisms on bone quality

*Kristina Wells[1], Sarah Mendoza[4], Alice Wong[1], Deepa Murugesh[3], Gabriela Loots[4], Clare Yellowley[5], Damian Genetos[6]. [1]UC Davis, United States. [4]University of California, Davis, . [3]Lawrence Lvermore National Lab, United States. [4]University of California, Davis, United States. [5]University of California School of Veterinary Medicine, United States. [6]University of California Davis, United States

Bone strength involves bone quantity and quality, with bone quantity receiving greater engagement and investigation than bone quality. Ideal osteoanabolic therapies will involve both the quantity and the quality of bone matrix. We have recently demonstrated that constitutive osteocytic oxygen sensing (degradation resistant HIF2a, HIF2cDR) or a regulatory protein upstream of oxygen sensing (Vhl cKO) produce unique high bone mass phenotypes. While both disruptions increase cortical and trabecular bone, HIF2cDR does not phenocopy Vhl KO either in quantity of bone produced or apparent bone organization. Understanding overlapping and unique contributions to bone quality in Vhl cKO vs. HIF2cDR will identify ideal targets for osteoanabolic therapies. We developed mice with osteocyte-enriched (10kb-Dmp1-cre) deletion of Vhl, Hif1a, or Hif2a or degradation-resistant HIF1A or HIF2A and established distinct impact of these deletions on bone strength, which was increased in Vhl cKO and reduced in HIF2cDR mice compared to wild-type controls. We next used ?CT to evaluate total mineral density distribution of knockout and transgenic femora. Both Vhl cKO and HIF2cDR mice had reduced mid-cortical peak mineral and mean mineral density, indicating impaired tissue material properties despite distinct impact on bone strength. Collagen alignment, analyzed by second-harmonic generation, was altered in each genotype relative to wild-type controls. Finally, we sought a potential mechanism for the differences in bone quality. SPARC - a matrix mineralization protein involved in collagen fibrillogenesis- is regulated by both hypoxia and Vhl in myriad cell types; absence of SPARC causes osteopenia and impairs both the organic and mineral content of bone. IHC staining revealed higher Sparc levels in both HIF2acDR and Vhl cKO compared to wild-type bones, with greater staining in Vhl cKO compared to Hif2cDR. In summary, manipulating oxygen-sensing pathways in osteocytes elicits high bone mass phenotypes with diverse outcomes on bone quality.DKM and GGL conducted work under the auspices of the USDOE by LLNL (DE-AC52-07NA27344)

Assessing Fracture Probability in Patients with Different Types of Fractures Using a Pretrained Artificial Neural Network Model Trained with Demographic, Anthropometric, and Densitometric (DXA) Characteristics

*Carlos Cure Cure[1], Sergio Luscher[2], Jose Ferretti[3], Gustavo Roberto Cointry[3], Ricardo Francisco Capozza[2]. [1]Biomelab Research Center , Colombia. [2]Center for P-Ca Metabolism Studies (CEMFoC), Natl Univ of Rosario and Arg NRC (CONICET), Argentina. [3]National University of Rosario,

Bone mineral density (BMD) by DXA is the reference for defining an individual's skeletal health status. We developed and validated an artificial neural network (ANN) model to evaluate this subject by demographic, anthropometric, and densitometric values and the corresponding fractured or non-fractured status into the ANN. After training, we can establish the probability of belonging to the fractured or non-fractured group.The study sample is 478 post-menopausal women (mean age 62.5 +/- 8.6 years) randomly selected from a sample of 1960 women divided into two equal groups of fractured (n: 239) and non-fractured (n: 239). Among the fractured women, only those previously regarded as osteoporotic and with low-trauma fractures were included. The sample was subdivided into 334 participants in the training set, 72 participants in the validation set, and the remaining 72 participants in the testing set, the latter consisting of women with fractures in various locations, namely: fx-humerus, fx-wrist, fx-spine, fx-hip, and fx-other-regions. The ANN input variables included age, weight, height, body mass index (BMI), lean mass (LM) of upper and lower extremities, trunk, and total body, and bone mineral content (BMC) of upper and lower extremities, trunk, and total body. The ANN outcome variable was dichotomous, established at 0 for non-fractured and 1 for fractured. The ANN was built with the training and validation data and tested with the testing set, the outcome variable of which was unknown to the network. The ANN performance was evaluated by simultaneous discrimination and calibration. After the training processes, the best final ANN was a multilayer perceptron network that determined 12 input variables (age, weight, height, BMI, LMs, and BMCs) as significant features. The ANN discriminant power for the test set was excellent (area under the ROC Analysis curve = 0.81 +/- 0.03).The test set of fractured women was evaluated by the neural network, and then the means and variances of the probabilities obtained in the different groups of fractured women were calculated. The probabilities obtained and the significance of the difference calculated compared to the group of women fractured in other regions were: fx-hip= 0.80 $p < 0.01$; fx-spine= 0.60 $p < 0.05$; fx-wrist= 0.65 $p < 0.05$; fx-humerus= 0.70 $p < 0.01$. We conclude that the trained neural network model can provide fracture probability values consistent with the osteoporotic or non-osteoporotic characteristic of the fracture site.

Assessment of osteoporosis and vertebral fracture risk by opportunistic bone mineral density (BMD) measurement on Choline PET/CT in patients with prostate cancer (Horm-Os Project) *Astrid Dauchez[1], Olivier Fogel[1], Charles Dariane[2], Jacques Fechtenbaum[1], Sylvain Bodard[3], Sylvain Guinebert[3], François Allioux[4], Marc-Olivier Timsit[2], Christian Roux[1], Fabien Hyafil[4], Karine Briot[1]. [1]Cochin Hospital, Rheumatology, France. [2]European Hospital Georges Pompidou, Urology, France. [3]Necker Hospital, Radiology, France. [4]European Hospital Georges Pompidou, Nuclear medecine, France

Androgen deprivation therapy (ADT) is central in the management of prostate cancer (PCa) but is associated with osteoporosis and fracture. DXA is recommended when starting ADT. Opportunistic measurement of bone mineral density (BMD) on CT has been proposed to improve osteoporosis screening. Choline PET/CT (chPET/CT) is frequently used to search for metastasis or relapse of PCa.The objectives were to demonstrate the feasibility of using chPET/CT in comparison to CT for opportunistic screening of osteoporosis and to describe pet/ct-derived BMD and prevalence of osteoporotic vertebral fracture in patients with PCa.We searched for PCa patients with chPET/CT from our tertiary center, then identified those with a CT within 6 months before or after the PET/CT for comparison. BMD estimation was performed on a 200mm² trabecular bone area on L1 vertebrae in axial section. Demographic and treatment information were collected. Spearman coefficient and t-test were used for continuous variables and chi square test for dichotomous variables.We identified 93 patients including 29 with a CT within 6 months. The mean age was 74 y-o, mean BMI was 27 kg/m², 12 patients had fractures, 20 had metastasis, 39 were already on ADT with a mean duration of 21.4 months. We compared chPET/CT and CT BMD values on the 29 patients who had both, the mean BMD were similar, 125 +/- 51 and 128 +/- 42 HU respectively and correlated well (k=0.7; p<0.001). The mean chPET/CT BMD of all patients was 125 HU +/- 51. Increasing age was significantly correlated with decreased BMD (k=-0.3; p<0.001). There was no correlation between BMI and BMD (k=0.02; p=0.87). The mean BMD in patients on ADT was 114 HU +/- 56, compared 127 HU +/- 42 in others (p=0.17), there was a trend toward a negative correlation between BMD and ADT duration (k=-0.3; p=0.1). We found a significant decreased BMD for patients with fracture (87 +/- 43 vs 131 +/- 49; p<0.01). A cut-off of 100 HU has been suggested to define risk for bone complications. The 23 patients with BMD<100 HU were more likely to have fracture compared to others (30% vs 7% of fracture; p<0.01).We demonstrated the feasibility of using chPET/CT for opportunistic screening for osteoporosis in PCa. Bone disease was frequent, 13% patients had fractures, 25% had BMD<100 HU. Pet/ct-BMD seemed useful for screening patients at risk of fracture. A prospective study will validate the interest of this approach and its impact on the management of osteoporosis in PCa patients.

SUN-376

The key importance of vertebral fractures rather than forearm fractures in the identification of high fracture risk of in younger postmenopausal women *Klaus Engelke[1], Claus-C Glueer[2], Frederike Thomasius[3], Bernd Schweikert[4], Jost von Petersdorff[5], Peyman Hadji[3], Alireza Moayyeri[6], Cesar Libanati[7]. [1]University Hospital Erlangen, Germany. [2]Christian Albrechts Universitaet zu Kiel, Germany. [3]Frankfurter Hormon- und Osteoporosezentrum, Germany. [4]Icon, Germany. [5]Algonaut GmbH, Germany. [6]UCB, United Kingdom. [7]UCB Biopharma srl,

Background: To identify patients at high(est) fracture risk, prior fracture history is key, particularly of fractures that are strong predictors of future fracture. Especially in younger postmenopausal women, forearm fractures (FF) are recognized as sentinel fracture. But vertebral fractures (VF) are stronger risk factors for subsequent VF and hip fractures (HF). Unfortunately, VF are often unrecognized, which may substantially contribute to the gap in osteoporosis care at younger age and the early stoppage of the fracture cascade. Aims: (1) To prove larger predictive power of VF compared to FF, hypothesizing that this advantage is even larger at younger age. (2) To identify a range of risk factors that facilitate identification of patients with high likelihood of prevalent vertebral fractures. Methods: We used a large representative German insurance database (DB), (a) to calculate absolute 1 and 3-year VF and HF risk after an index VF or FF, (b) to determine out of 32 cRF previously identified by a literature review of 2267 peer-reviewed publications those that best predicted VF fracture. Predictive power of cRFs was examined using age-adjusted sex-specific Cox proportional hazard models including interactions between the selected predictor and age. Calculations were performed separately for age ranges of 50-70 and 70-90 years. Results: The DB included 214,453 women aged 50-70 and 154,221 aged 70-90. VF were better index fractures than FF to predict subsequent VF (table). At younger age, the predictive power was 5-10 fold stronger for VF compared to FF for prediction of VF. At young age VF were also stronger predictors for HF with comparable strength of VF and FF for prediction of HF at older age. We identified 11 cRF with HR>3.0 and another 10 cRF with HR>2.0 associated with VF in the last 4 years. Discussion: Diagnosis of VF is important for fracture risk determination especially at younger age. Risk factor gradients of VF decline with age but are higher compared to forearm fractures. As hip fractures are rare at younger age, VF rather than FF, need more attention to overcome the in osteoporosis care gap in younger age groups. The large number of 20 cRF with strong association with prevalent VF indicates realistic potential to develop better strategies, e.g. using advanced diagnostic procedures such as VFA. This will substantially improve the identification of high-risk patients to help reduce costly fractures later in life and improve patients' lives.

predictor	Age adjusted HR for incident VF				Age adjusted HR for incident HF			
age range	50-70		70-90		50-70		70-90	
years after index fx	1	3	1	3	1	3	1	3
VF	63.5	18.0	8.9	5.3	7.6	3.2	1.6	1.9
FF	3.6	2.8	1.8	1.7	4.5	2.4	1.9	1.8

cRF with HR≥3.0: Morbus Alzheimer, Morbus Parkinson, falls, immobility, hip fx, hypernatremia, MGUS, oral glucocorticoids (high dose), peripheral arterial disease, schizophrenia, transplantations,
additional cRF with HR≥2.0: anticoagulants, COPD, pulmonary hypertension, atrial fibrillation, Cushing syndrome, growth hormone deficiency, heart failure, stroke, opioids, oral glucocorticoids (low/medium dose)

Variance in Bone Strength is conferred by Diversity of its Structure *Ali Ghasem-Zadeh[7], Haniyeh Hemmatian[2], Olga Panagiotopoulou[3], Phil Salmon[4], Rita Hardiman[2], Narelle McGregor[5], Natalie Sims[6], ego seeman[7]. [7]Austin Health, University of Melbourne, Australia. [2]The University of Melbourne, Australia. [3]Monash University, Australia. [4]Bruker-MicroCT, Belgium. [5]St. Vincent's Institute of Medical Research , Australia. [6]St. Vincent's Institute of Medical Research, Australia. [7]Austin Health, University of Melbourne,

Introduction Resistance to fracture is achieved by adding bone to, and removing bone from, its periosteal and three components of its endosteal surface. These events modify the spatial distribution and mineral content of the bone volume without necessarily alerting its mass. In tubular bones, similar amounts of bone are used to assemble large differences in the size, shape, and microarchitecture of adjacent cross sections along the length of bone 1,2. We hypothesized that i) in vitro, differences in size, shape, and architecture of adjacent cross-sections along the whole length of a bone are assembled using differences in void volume, not bone volume, ii) likewise, in vivo, regional differences in bone morphology are largely achieved by differences in void volume, not bone volume.Methods We quantified macro-structure of the cross-sections of 5 radii and 5 femora using CT-Scan (300 microns) and micro-structure of the cross-sections of the distal and proximal metaphyseal-diaphyseal regions (1/3 of bone length) of 18 radii and 5 femora using HR-pQCT (82 micron). Distal radius and tibia of 94 women (age:57+/- 6.3 yrs.) scanned by HR-pQCT. Finite element analysis was used to estimate bone strength.Results Bone mass was constant along the diaphysis of radii, the femoral neck and along the distal third of the femur (Fig). Along the metaphysis, the constant mass was fashioned with a large void volume and high surface area/matrix volume (trabecular bone) while at the mid-diaphysis the same mass was fashioned with a small intracortical and medullary void volume and low surface area/matrix volume (cortical bone). Preliminary FEA showed a reduction in strains in areas with increased cortical thickness and the moment of inertia. In-vivo results revealed that larger bones are assembled with relatively less cortical mass, which is characterized by higher cortical porosity and lower matrix mineral density.Conclusion Larger bones are not assembled using more mass, they are assembled using more void - mass is minimized to facilitate mobility. Moreover, maintaining optimal strains is achieved by diversity in structure more than mass.References:1. Ghasem-Zadeh A, et al. Bone. 2017 Aug; 101:206-213. PMID: 28502884 2. Zebaze RM, et al. Physical Function Tests for the Prediction of Fracture Risk in Older Women

*Giulia Gregori[1], Lisa Johansson[2], Kristian Axelsson[3], Henrik Litsne[1], Mattias Lorentzon[4]. [1]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, Sweden. [2]Institute of medicine, . [3]Institute of Medicine, Sahlgrenska Academy, Gothenburg University, . [4]Sahlgrenska Academy, University of Gothenburg, Sweden

Background: Physical function is an important risk factor for fracture. Previous studies have found that physical tests including the one leg standing (OLS) time and timed up and go test (TUG) predict fracture risk. The aim of this study was to determine which physical function test is the most optimal predictor of fracture risk when adjusting for clinical risk factors (CRFs), used in the fracture risk assessment tool (FRAX), and bone mineral density (BMD).Methods: In total, 2,321 Swedish women 77.7?1.6 years old (mean?SD) from the SUPERB study were included in this analysis. Five different physical function tests were conducted at baseline: hand grip strength, OLS, TUG, gait speed, and chair stand test. Incident fractures were identified using by X-ray or review of medical records and subsequently categorized as major osteoporotic fractures (MOF; hip, spine, proximal humerus, and forearm), hip fractures, and any fractures. Multivariate Cox regression (hazard ratios [HR] and 95% confidence intervals [CI]) analyses were performed to investigate the association between all physical function tests (included in the same model) and incident fracture, with age, body mass index (BMI), FRAX CRFs and femoral neck (FN) BMD used as covariates. Results: During a median (IQR) follow-up time of 7.5 (2.9) years (IQR), there were 579 (24.9%) MOF, 163 (7%) hip fractures and 779 (33.6%) any fractures. After adjusting for age, BMI, CRFs included in FRAX, and additionally for BMD, OLS was the only physical function test consistently associated with increased risk of all fracture outcomes (Table). Gait speed was only associated with the risk of hip fracture regardless of adjustment, and chair stand test with MOF and any fracture only in fully adjusted models (Table).Conclusions: Among the five physical function tests, this study demonstrates that OLS time is the strongest predictor of MOF, hip fracture, and any fracture in older women, indicating that this test should therefore be considered as an additional assessment tool for improving fracture prediction in older women.

Table. Association between physical function tests and fracture risk in older women.

	Grip Strength (N)	One Leg Standing (s)	Time Up and Go (s)	Gait Speed (m/s)	Chair Stand (n/s)
	HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)
Major osteoporotic fracture					
Model 1	1.01 (0.93 to 1.11)	**1.14 (1.04 to 1.26)**	0.94 (0.84 to 1.05)	**1.12 (1.00 to 1.26)**	1.08 (0.98 to 1.20)
Model 2	0.99 (0.91 to 1.09)	**1.12 (1.02 to 1.24)**	0.96 (0.87 to 1.08)	1.11 (0.99 to 1.24)	**1.11 (1.01 to 1.22)**
Hip fracture					
Model 1	1.03 (0.87 to 1.22)	**1.32 (1.10 to 1.60)**	1.03 (0.84 to 1.26)	**1.34 (1.09 to 1.66)**	1.14 (0.95 to 1.36)
Model 2	0.99 (0.83 to 1.17)	**1.30 (1.06 to 1.55)**	1.08 (0.88 to 1.31)	**1.29 (1.05 to 1.60)**	1.19 (0.99 to 1.43)
Any fracture					
Model 1	1.01 (0.94 to 1.09)	**1.13 (1.04 to 1.22)**	0.94 (0.85 to 1.04)	1.09 (0.99 to 1.21)	1.07 (0.98 to 1.17)
Model 2	0.99 (0.92 to 1.07)	**1.11 (1.02 to 1.20)**	0.97 (0.88 to 1.06)	1.09 (0.98 to 1.20)	**1.10 (1.01 to 1.20)**

Associations were studied using Cox proportional hazard models. Hazard ratios (HR) per SD are shown with 95% Confidence Intervals. Significant HRs are shown in bold. All physical function test variables were included simultaneously. Model 1: adjusted for age, BMI, CRFs included in FRAX (previous fracture, family history of hip fracture, current smoking, rheumatoid arthritis, oral glucocorticoid use, alcohol consumption, secondary osteoporosis). Model 2: model 1 + Femoral Neck BMD.

Assessment of Trabecular Bone Score using updated TBSTT on top of bone mineral density, body composition and bone turnover markers in Anorexia Nervosa - The AN-BO Study

*Judith Haschka[1], Martina Behanova[1], Didier Hans[2], Annina Arens[1], Christian Muschitz[3], Larisa Dzirlo[4], Julia Binder[5], Jochen Zwerina[1], Heinrich Resch[6], Roland Kocijan[1]. [1]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of OEGK and AUVA Trauma Center Meidling, 1st Medical Department Hanusch Hospital, Vienna, Austria. [2]Centre des Maladies Osseuses-Département de l'Appareil Locomoteur, Hôpital Orthopédique, Lausanne, Switzerland. [3]St. Vincent Hospital, Medical Department II, Vienna, Austria. [4]St. Vincent Hospital, Medical Department III, Vienna, Austria. [5]Department of Obstetrics and Gynecology, Medical University of Vienna, Vienna, Austria. [6]Karl Landsteiner Institute for Gastroenterology and Rheumatology at Rheuma-Zentrum Wien Oberlaa and St. Vincent Hospital, Medical Department II, Vienna, Austria

BackgroundAnorexia Nervosa (AN) is a well-known risk factor for secondary osteoporosis. Despite low bone mineral density (BMD), reduced trabecular bone score (TBS) in AN has been reported previously. Presence of soft tissue leads to alterations in X-ray absorption, may underestimate TBS values and is especially of interest when comparing patient populations with different body compositions. The updated TBS software (TBS iNsight®v4.0) provides a new algorithm accounting for soft tissue thickness (TBSTT) instead of body mass index (BMI, TBSBMI).Purpose & MethodsThe aim of the study was to assess TBS using both TBS algorithms (TBSTT and TBSBMI) in adult females with AN compared to controls (CTRL). Further, BMD (lumbar spine LS; total hip; femoral neck; body composition: lean body mass LBM; fat mass FM; bone mineral content, BMC; GE Lunar iDXATM) as well as 25(OH)vitamin D, bone turnover markers (BTM; CTX, P1NP) and serum sclerostin levels were assessed. Differences between groups were evaluated by independent-samples T-test or Mann-Whitney U test. Results are presented as mean+/-SD or median(IQR), depending on normality distribution.Results60 female patients with AN (N=34) and CTRL (N=26) of comparable age (22.8 (7.1) vs. 25.0 (4.0) years, p=0.145) but different BMI (14.7 (1.6) vs. 22.4 (4.0), p<0.001) were analyzed. TBSTT (1.319+/-0.09 vs.1.502+/-0.07, p<0.001) and TBSBMI (1.317+/-0.10 vs.1.548+/-0.09, p<0.001) were significantly lower in AN patients. Soft tissue thickness was lower in AN (cm, 13.8+/-1.0 vs.18.6+/-2.1, p<0.001). BMD at all sites of AN patients were reduced (p<0.001 for all), being lowest at LS (0.973+/-0.149 vs. 1.289+/-0.146). TBSTT and TBSBMI correlated with BMD at all sites (p<0.001). BMC, LBM and FM were decreased in AN (p<0.001). AN patients had lower 25(OH)vitamin D (ng/ml; 26.7+/-11.0 vs. 32.9+/-9.5, p=0.028) and P1NP (36.9 (42.5) vs. 47.4 (31.9), p=0.05), but higher CTX (0.73 (0.5) vs. 0.37 (0.3), p=0.001) and sclerostin (12.6 (10.0) vs.8.7(6.9), p=0.003). Duration of amenorrhea was negatively correlated with TBSBMI (?=-0.36, p=0.05) and BMD of LS (?=-0.64, p<0.001).ConclusionAdult AN patients have lower TBSTT and TBSBMI despite reduced BMD at all sites. BTM indicate an uncoupling of bone turnover in AN patients.Differences in soft tissue thickness were displayed by the new algorithm. Although, the impact in these cohorts of under- and normal-weight controls was low, greater differences may arise if body composition varies despite comparable BMI.

Microstructural Imaging of Bone by Photon-Counting Detector Computed Tomography

*Andrew Burghardt[1], Aida Korajac[2], Andreas Strassl[2], Saghi Sadoughi[3], Galateia Kazakia[1], Janina Patsch[2]. [1]University of California, San Francisco, United States. [2]Medical University of Vienna, Austria. [3]UCSF,

The quantification of bone quality by high-resolution peripheral quantitative computed tomography (HR-pQCT) improves fracture risk prediction1, however few systems are available worldwide, they are exclusively approved for research purposes, and the technology is limited to imaging the peripheral skeleton. In the last year clinical CT systems with photon counting detectors (PCD-CT) - a generational advance in imaging performance - have been introduced2. The goal of this study was to evaluate the accuracy of PCD-CT for bone structure quantification.Cadaveric phantoms comprised of 20 1-cm metaphyseal sections of distal radius and tibia bone3 were imaged by µCT (24.5µm), 1st- and 2nd-generation HR-pQCT (82µm, 61µm), and PCD-CT (Naeotom Alpha, Siemens Healthineers). PCD-CT scans were acquired at 120kVp in Ultra-High Resolution (UHR) mode (200mAs, 16.1mGy). A 15mm FOV was reconstructed across 1024x1024 matrix using the Br92 kernel (146µm pixel size, 150µm slice thickness). Spatial resolution (10% MTF) and noise performance (SNR) were measured in idealized density and wire phantoms. Standard density, geometry, and structure measures were quantified from the cadaveric phantom images and evaluated for accuracy by linear regression and Bland-Altman analysis.Scan time for each bone section was <10s for PCD-CT, compared to 3.2 and 2.0 minutes for 1st and 2nd-gen HR-pQCT. Qualitatively, PCD-CT provides an exquisite depiction of cortical and trabecular microstructural features (Fig. 1, top). PCD-CT noise performance (SNR=20.5) was superior to 1st- and 2nd-gen HR-pQCT (SNR=15.4 and 7.1). The spatial resolution of PCD-CT (10% MTF = 132 µm) was comparable to 1st-gen HR-pQCT (10% MTF = 138 µm), and inferior to 2nd-gen HR-pQCT (10% MTF = 95 µm). Accuracy of PCD-CT was high (R2>0.9) for BV/TV and Tb.N, and comparable to HR-pQCT (Fig.1, bottom).Photo-counting detector CT provides significant advantages for measuring human bone structure in vivo, including superior noise performance and scan time, while spatial resolution is comparable to 1st-gen HR-pQCT and accuracy was comparable to 2nd-gen HR-pQCT. Given the potential for wide availability and existing regulatory approval, PCD-CT represents an exciting opportunity to translate quantitative microstructural skeletal imaging to a clinical platform.1 Langsetmo L, et al., doi: 10.1002/jbmr.34332 Hsieh SS, et al., doi: 10.1109/trpms.2020.30202123 Burghardt AJ, et al., doi: 10.1002/jbmr.1795

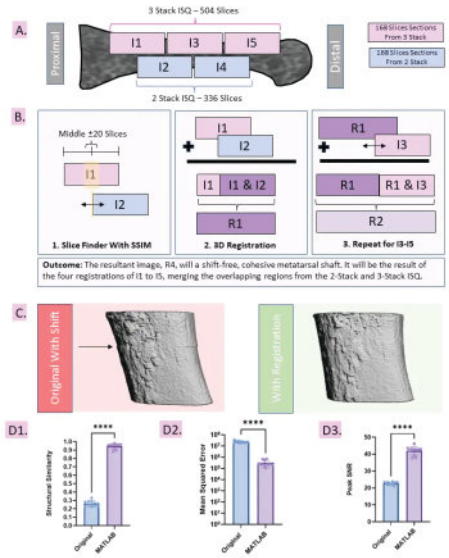

Figure 1 – (A) The 3-Stack and 2-Stack HR-pQCT ISQ files were divided into 168 slice subregions. These subregions were labeled accordingly. (B) These subregions were pulled into the custom MATLAB code for registration into a single, cohesive scan. A "slice finder", governed by the structural similarity index function, selected identical slices from the adjacent subregions. As shown in this first box, the first slice of I2 was compared to 40 different slices in I1 with this "slice finder" until an identical image was identified. Next, I1 and I2 were registered starting at the matching slice. This created R1, or the first registered subregion. Following this, the cycle was repeated, but using R1 and I3. This process was continued for four registrations, until (C) a complete, cohesive image was reconstructed. (D1) Structural similarity index and (D3) peak signal to noise ratio were significantly increased ($p<0.0001$) and the mean square error (D2) was significantly decreased ($p<0.0001$).

Custom MATLAB Registration Script for Stack Shift Correction of Multistack HR-pQCT Scans of the Metatarsals *Andrea Jacobson[1], Austin Sventeckis[2], Michael Kuczynski[3], Sarah Manske[4], Stuart Warden[5], RACHEL SUROWIEC[6]. [1]Department of Biomedical Engineering, Indiana University Purdue University Indianapolis, United States. [2]Department of Physical Therapy, Indiana University Purdue University Indianapolis, United States. [3]McCaig Institute for Bone and Joint Health, Department of Radiology, Cumming School of Medicine, University of Calgary, Canada. [4]University of Calgary, Canada. [5]Indiana University School of Health & Human Sciences, United States. [6]Indiana University Purdue University,

The metatarsals are commonly injured in athletes and military recruits as well as in some disease states (e.g. Charcot neuropathy). High resolution peripheral quantitative computed tomography (HRpQCT) is a novel tool for measuring bone parameters in vivo. Scan stacks are limited to 168 slices (10.2mm), and each new stack creates a "stack shift" which could alter evaluation outcomes. Metatarsal pathologies may extend beyond the 10.2mm single stack length, necessitating a protocol for correcting stack shifts. This work aimed to create a stack shift correction to enable accurate assessment of multistack metatarsal HRpQCT scans.A convenience sample of two participants had two HRpQCT scans (Scanco XtremeCTII) taken of the metatarsal forefoot region: one 2-stack scan (336 slices) and one 3-stack (504 slices) centered at the midshaft of the 2nd metatarsal (voxel 60.7 µm). The stacks were positioned to overlap at points of stack shift, which would occur at slices 168 and 336 in the 3-stack scan (Fig.A). The first, second, and third metatarsals were cropped from each data set to test the reconstruction of 6 unique bones. The stacks were divided into 168 slice subregions (Fig. A) and imported to MATLAB for image registration. To register these images, the custom code had two main functions. First, as shown in Figure B, the "slice finder" used structural similarity index (SSIM) to find the most similar slices between neighboring subregions. Next, four 3D registrations were performed until all neighboring subregions were combined into one cohesive image, as shown in Figure C. The two slices adjacent to each stack shift (slices 168-169 and 336-337) were compared before and after the registration (n=12) using three metrics: SSIM, mean squared error (MSE), and peak signal to noise ratio (PSNR). Paired one-tailed t-tests were run to evaluate each metric's before and after registration results.The SSIM value was significantly larger ($p<0.0001$) post-registration and close to a value of 1 (0.95+/-0.03) compared to prior to the registration (0.26+/-0.03) (Fig. D1). The MSE was significantly lower post-registration ($p<0.0001$) (Fig. D2). Additionally, the PSNR value was significantly larger ($p<0.0001$) post-registration (Fig. D3).The custom MATLAB registration script significantly improved the stack shift in both regions of the metatarsal scan. With these promising results, next steps are to perform microarchitectural and mineral density analyses on resultant, registered images.

SUN-382

Cortical thickness as measured by 3D-DXA is associated with prior fracture in Blacks but not Whites when controlling for age and areal BMD T-score *Rajesh Jain[1], Mirella López Picazo[2], Ludovic Humbert[2], Tamara Vokes[1]. [1]University of Chicago, United States. [2]3D-Shaper Medical, Spain

Introduction: Black patients are known to have greater areal BMD (aBMD) than White patients. Some studies suggest aBMD may not be as predictive of fracture in Black patients, and Black patients are known to fracture at about 50% the rate at a given aBMD. Some of these differences appear to relate to differences in bone structure. New software can provide quantitative CT-like 3D models based on 2D hip DXA images, allowing for analysis of cortical and trabecular volumetric parameters from routine DXA. We sought to determine whether there were differences between Black and White patients in 3D-DXA parameters and/or their association with fragility.Methods: This is a secondary analysis of patients previously recruited as part of their clinical care at an osteoporosis center in Chicago, IL. Patients with active cancer were excluded. All patients had undergone a fracture questionnaire, a DXA scan, and vertebral fracture assessment (VFA). 3D-SHAPER software (v2.12, 3D-Shaper Medical, Spain) was retrospectively run on hip DXA scans. 95% patients had DXA of both femurs, and the worst parameter was used in analysis. We analyzed either vertebral fracture on VFA or history of fracture after the age of 50 as an outcome of bone fragility. We compared 3D-DXA parameters by race using t-tests, and we used logistic regression to analyze the association between fractures and 3D-DXA parameters.Results: There were 368 Black and 407 White women with Blacks being older but with greater aBMD (Table 1). Cortical surface BMD and total hip volumetric BMD (vBMD) measurements were strongly correlated with total hip aBMD (correlation coefficient p= 0.90-0.97, $p<0.001$ for all), while cortical thickness of the femoral neck less so ($p=0.43$, $p<0.001$).Most 3D-DXA parameters were superior in Blacks vs. Whites (Table 1). When adjusting for age only, total hip trabecular, cortical, and integral vBMD were associated with fracture in Whites, but not Blacks (per SD worsening: OR 1.7-2.2, $p<0.001$ vs. OR 1.1-1.2, p=NS, respectively). When also adjusting for lowest T-score, trabecular vBMD of the total hip was the strongest 3D-DXA predictor of prior fracture in Whites, but in Blacks we found that cortical thickness of the femoral neck was the strongest predictor.Conclusion: 3D-DXA software demonstrates superior bone structure in Black patients, and cortical thickness of the femoral neck may be an important parameter to uniquely predict fracture in Black patients.

	3D-DXA Parameters		Associations with Fracture[1]	
	Black (368)	White (407)	Black (368) OR per SD worsening	White (407) OR per SD worsening
Age	69.4 ± 11.0	63.8 ± 11.1	-	-
Lowest T-score	-2.0 ± 1.2	-2.4 ± 1.0	-	-
Fracture history	23.4%	27.5%	-	-
Integral vBMD (TH), mg/cm³	288.3 ± 61.1	269.5 ± 51.0	0.6 (0.4-1.0, p=0.06)	1.6 (0.9-2.8, p=0.08)
Trabecular vBMD (TH), mg/cm³	141.2 ± 43.1	127.2 ± 37.3	0.7 (0.5-1.1, p=0.13)	**1.8 (1.1-3.0, p=0.02)**
Cortical vBMD (TH), mg/cm³	768.3 ± 92.2	754.1 ± 79.6	**0.6 (0.4-0.9, p=0.02)**	1.2 (0.8-1.8, p=0.49)
Cortical Surface BMD (TH), mg/cm²	144.4 ± 27.0	137.3 ± 21.7	0.7 (0.4-1.1, p=0.14)	1.2 (0.7-2.0, p=0.57)
Cortical thickness (TH), mm	1.84 ± 0.16	1.79 ± 0.13	1.2 (0.9 – 1.8, p=0.21)	0.9 (0.6 – 1.4, p=0.79)
Cortical thickness (FN), mm	1.60 ± 0.18	1.51 ± 0.14	**1.5 (1.1 – 2.0, p=0.009)**	0.8 (0.6-1.1, p=0.24)
Cortical thickness (lateral FN), mm	1.01 ± 0.12	0.97 ± 0.10	**1.5 (1.2-1.9, p=0.002)**	0.9 (0.7-1.2, p=0.44)
Cortical thickness (medial FN), mm	2.72 ± 0.34	2.53 ± 0.26	1.3 (1.0 – 1.7, p=0.08)	0.8 (0.6 – 1.1, p=0.15)

[1]Controlled for Age and lowest areal BMD T-score
TH: total hip; FN: femoral neck, SD: standard deviation, OR: odds ratio
Bold 3D-DXA parameters are significantly different across race; bold odds ratio are statistically significant.

Portable USB-powered Radiation-free Bone Mineral Density Measurement at the 1/3 Radius *Jonathan Kaufman[1], Gangming Luo[1]. [1]CyberLogic, Inc., United States

The goals of this study were to determine the ability of a new clinical ultrasound device (UltraScan 650, CyberLogic, Inc., NY, USA, Fig. 1) to estimate bone mineral density (BMD) at the 1/3 radius.The UltraScan 650 is a portable USB-powered tabletop sonometer, and performs evaluation of the BMD with a 10 second radiation-free test. The device measures the radius in thru-transmission, and computes the BMD in grams per square centimeter, as would be measured by DXA. A clinical IRB-approved study was carried out in which 77 adults (age range 21-83, 75% female) were measured at the 1/3 radius using the UltraScan 650 and DXA (Hologic QDR 4500). BMD ranged from 0.45 - 0.92 g/cm2). A linear regression showed that BMD obtained with the UltraScan 650 and the BMD obtained with DXA had a linear (Pearson) correlation of 0.93 (P<0.001). The data presented demonstrate that the UltraScan 650 is an excellent proxy for BMD as would be measured by DXA at the 1/3 radius. Indeed, we found that forearm ultrasound measurements yield results that are very closely associated with those from DXA. These clinical results are also consistent with previously reported simulated and in vitro studies, and the present clinical data provides strong support for the proposed methods in ultrasonically estimating BMD. A new device, the UltraScan 650, has been shown to have the potential to enlarge the scope of ultrasound bone assessment in particular and of bone screening in general.The portability and simplicity in use of the radiation-free ultrasound scanner, combined with its high degree of accuracy and precision in estimating radial BMD, provides a basis by which to expand ultrasonic assessment to the primary and community care settings. This will in turn provide an opportunity to reduce the incidence of osteoporotic fractures through early and timely therapeutic interventions.

Prediction of progressive collapse in osteoporotic vertebral fractures using conventional statistics and machine learning *Jin Hwan Kim[1], Sung Tan Cho[2], Soonchul Lee[3], Hyun Il Lee[4]. [1]Inje University, Ilsanpaik Hospital, Republic of Korea. [2]INJE University ILSANPAIK Hospital, Republic of Korea. [3]Department of Orthopaedic Surgery, CHA University School of Medicine, Republic of Korea. [4]Department of Orthopedic Surgery, Ilsan Paik Hospital, Inje University, Republic of Korea

Background: Few studies have investigated the risk factors of progressive osteoporotic vertebral fracture (OVF). Furthermore, machine learning has not been applied in this aspect. The purpose of this study is to determine prognostic factors for the progression of OVF following conservative treatment.Methods: The study involved the progression of collapse (PC) and non-PC groups based on the compression rate (15%). Clinical data, fracture site, OVF shape, Cobb's angle, and anterior wedge angle of the fractured vertebra were evaluated. The presence of intravertebral cleft and the type of bone marrow signal change were analyzed using magnetic resonance imaging. Multivariate logistic regression analysis was performed to identify prognostic factors. In machine learning methods, decision tree (DT) and random forest (RF) models were used.Results: There were no significant differences in clinical data between the groups. The proportion of fracture shape (p<0.001) and bone marrow signal change (p=0.01) were significantly different between the groups. Moderate wedge shape was most observed in the non-PC group (31.7%), whereas the normative shape was most observed in the PC group (54.7%). The Cobb's angle and anterior wedge angle at diagnosis of OVFs were higher in the non-PC group (13.2+/-10.9; p=0.001, 14.3+/-6.6; p<0.001) than in the PC group (10.3+/-11.8, 10.4+/-5.5). The bone marrow signal change at the superior aspect of the vertebra was more frequently found in the PC group (42.5%) than in the non-PC group (34.9%). Feature importance using machine learning revealed that vertebral shape at initial diagnosis was the main factor of progression of vertebral collapse. Furthermore, the RF model was better at predicting progression (AUC=0.727, multivariate logistic regression=0.724, DT=0.688).Conclusion: The initial shape of the vertebra and bone edema pattern on MRI are useful prognostic predictors for the progression of collapse in OVFs.

Opportunistic Vertebral Fracture Detection from Computed Tomography Studies by Artificial Intelligence - preliminary results *Daniel Arian Kraus[5], Shahin Zandieh[2], Judith Haschka[3], Heinz Redl[4], Jochen Zwerina[5], Roland Kocijan[5]. [5]Ludwig Boltzmann Institute of Osteology, Austria. [2]Department for Radiology and Nuclear Medicine at Hanusch hospital of OEGK, Austria. [3]Ludwig Boltzmann Institute for Osteology, Hanusch Hospital Vienna, . [4]Ludwig Boltzmann Institute of Traumatology, Austria. [5]Ludwig Boltzmann Institute of Osteology,

IntroductionVertebral fractures belong to the most common osteoporotic fractures, although not always clinically evident. Nevertheless, vertebral fractures increase the risk of further osteoporotic fractures and require assessment and treatment in most cases. The aim of this preliminary analysis was to identify higher grade vertebral fractures by the prototype of a deep learning artificial intelligence software in a high-risk collective of patients with pulmonary diseases.MethodsThe artificial intelligence Flamingo (ImageBiopsy Lab®) detects vertebral fractures from thoracic and abdominal computed tomography (CT) studies. It can be applied to already existing CT scans and predicts a class probability for every voxel using a 3-dimensional convolutional neural network. This retrospective analysis comprised 30 patients with thoracic and/or abdominal CT studies from the pulmonary outpatient clinics of Hanusch hospital Vienna. In total, 458 vertebral bodies from T1-L4 were analyzed. CT studies were screened for fractures by a trained radiologist and classified according to the Genant classification. In the next step, the same CT studies were reviewed by Flamingo for vertebral fractures and classified into no fracture (Genant 0/1), moderate fracture (Genant 2) and severe fracture (Genant 3). Sensitivity and specificity were tested.ResultsDatasets of 29 subjects (mean age 76 +/- 9.9, 51.7 % male) were available. In total, 19 higher-graded vertebral fractures in 9 subjects were identified by the radiologist. Flamingo correctly identified 76 % of subjects (22 out of 29) with fractures (Genant 2/3) and without (Genant 0/1) compared to the radiologist. Furthermore, 69 % of subjects (20 out of 29) were correctly classified in no fracture (Genant 0/1), Genant 2 or Genant 3 fracture compared to the radiologist. Moreover, in 14 % of subjects (4 out of 29) at least 1 fracture (Genant 2/3) was identified correctly, whereas the remaining subjects (10.3 %, 3 out of 29) were assessed incorrectly. Overall, Flamingo reported a sensitivity of 89.5 % and specificity of 98.0 % for identification of higher-grade vertebral fractures (Genant 2/3).ConclusionThe artificial intelligence Flamingo revealed promising preliminary results in opportunistic fracture detection of higher-grade vertebral fractures (Genant 2/3) from existing CT scans. The application of artificial intelligence could reduce the gap of undiagnosed and untreated vertebral fractures and thus osteoporosis.

Osteosarcopenia Presents a Risk for Self-Reported Incident Falls, Fractures, Frailty, Life Satisfaction and Activities of Daily Living in Community-Dwelling Older Adults: Results From the Canadian Longitudinal Study on Aging (CLSA) *Ahreum Lee[1], Caitlin McArthur[2], George Ioannidis[1], Gustavo Duque[3], Jonathan D Adachi[1], Lauren E Griffith[1], Lehana Thabane[1], Alexandra Papaioannou[1]. [1]McMaster University, Department of Health Research Methods, Evidence, and Impact, Canada. [2]Dalhousie University, School of Physiotherapy, Canada. [3]Dr. Joseph Kaufmann Chair in Geriatric Medicine, Department of Medicine, McGill University, Canada

Background/Purpose: To investigate whether older adults with osteosarcopenia have a higher risk of experiencing falls, fractures, frailty, decline in life satisfaction, limitations in activities of daily living (ADL), and reduced physical function compared to those without osteopenia/osteoporosis and sarcopenia.Methods: This study included Caucasian participants aged 65 years or older who completed physical measurements at baseline and a 3-year follow-up within the Canadian Longitudinal Study on Aging (CLSA) 2015 comprehensive baseline interview. Osteopenia/osteoporosis was defined as a BMD T-score -1 standard deviation (SD) by the World Health Organization definition, and sarcopenia was defined by the Sarcopenia Definition Outcomes Consortium, which involves low grip strength and/or low gait speed. Osteosarcopenia was defined as the coexistence of osteopenia/osteoporosis and sarcopenia. This study assessed any self-reported incident falls and fractures occurring within the 12 months prior to the 3-year follow-up, as well as frailty (measured through the Rockwood Frailty Index), life satisfaction (measured through the Satisfaction With Life Scale, SWLS), ADL (measured through the Older American Resources and Services Modules), and physical function (measured through timed up and go, chair rise, and standing balance tests). We conducted multivariable logistic and linear regressions, with subgroup analyses conducted by sex. Odds ratio (OR), coefficient (?) and 95% confidence intervals (CI) are reported.Results: This study included a total of 8,888 participants with a mean (SD) age of 72.7 (5.6) years, of which 49.1% were females. At baseline, 30.1% of participants had neither osteopenia/osteoporosis nor sarcopenia, 18.4% had sarcopenia only, 29.2% had osteopenia/osteoporosis only, and 22.3% had osteosarcopenia. The results showed that males with osteosarcopenia had a higher risk of experiencing incident falls and fractures compared to males without osteopenia/osteoporosis or sarcopenia, with an adjusted odds ratio of 1.90 (95% CI: 1.15, 3.14) and 2.60 (95% CI: 1.14, 5.91), respectively. In addition, participants with osteosarcopenia had worse ADLs and a decrease in their SWLS than those without, with an estimated ? 0.110 (95% CI: 0.029, 0.192) and -0.660 (95% CI: -1.133, -0.187), respectively.Discussion/Conclusions: Osteosarcopenia presents a greater risk for self-reported incident falls and fractures among males, as well as poorer life satisfaction and ADL for females and all participants.

Parental History of Hip Fracture and Future Fracture Risk: an International Meta-analysis to Inform Updates of FRAX *Eugene McCloskey[5], Helena Johansson[2], Nicholas Harvey[3], Enwu Liu[4], Marian Schini[5], Liesbeth Vandenput[4], Mattias Lorentzon[6], William Leslie[7], John Kanis[4], and the FRAX Meta-analysis Cohort Group [8]. [5]University of Sheffield, United Kingdom. [2]University of Gothenburg, Sweden. [3]University of Southampton, . [4]Australian Catholic University, Australia. [5]University of Sheffield, . [6]Sahlgrenska Academy, University of Gothenburg, Sweden. [7]University of Manitoba, Canada. [8], United Kingdom

We have undertaken a meta-analysis of international prospective cohorts to quantify the relationship between a parental history of hip fracture history and future fracture incidence. We additionally explored the predictive value of this risk factor when adjusted for age, sex, time since baseline and femoral neck bone mineral density (BMD).The analysis dataset comprised 281893 men and women from 40 cohorts in 28 countries followed for a total of 2.42 million person-years. We investigated the relationship between parental hip fracture history and the risk of any clinical fracture, any osteoporotic fracture, major osteoporotic fracture (MOF) and hip fracture alone using an extended Poisson model in each cohort. Covariates examined were age, sex, BMD and duration of follow up. The results of the different studies were merged by using the weighted ?-coefficients.After adjustment for age and time since baseline, a parental history of hip fracture was associated with higher risk of incident fracture across all of the fracture outcome categories in both men and women. For example, the hazard ratio [HR (95% CI)] for MOF was 1.21 (1.13-1.29) in women and 1.18 (1.05-1.33) in men, with no difference between the sexes. The association appeared stronger for the prediction of incident hip fractures alone (1.40, 1.26-1.56 and 1.37, 1.05-1.80 in women and men respectively). Associations were similar in the subset of cohorts in which BMD was measured and the relationship was largely unchanged when BMD was included in the analysis. Furthermore, the magnitude of associations did not vary by age and/or follow-up time. In this large international cohort meta-analysis, parental history of hip fracture increased the risk of future fracture, especially hip fracture. The association appears independent of sex, age and femoral neck BMD. We conclude that parental history of hip fracture should continue to play a role as an important, easily captured, fracture risk factor in future iterations of tools such as FRAX.

Defining Imminent Risk Using FRAX Multipliers for Patients with Recent Fragility Fractures *Prism Schneider[2], Kaja Matovinovic[2]. [2]University of Calgary, Canada. [2]University of Calgary,

Purpose: The Fracture Risk Assessment Tool (FRAX) estimates a 10-year probability of major osteoporotic fracture (MOF) using clinical risk factors, including prior fracture history as a binary variable. However, prior fractures affect future risk differently depending on recency and site, with MOF risk being highest in the first two years following an index fracture (imminent risk). Therefore, the FRAX tool may underestimate true risk, resulting in missed opportunities for osteoporosis management. To address this, multipliers based on age, sex, and fracture type have been proposed to adjust FRAX scores. Modified FRAX scores may more accurately predict MOF risk in patients with recent fragility fractures, allowing earlier identification of those eligible for pharmacologic intervention. Methods: Standard and modified FRAX scores were calculated for patients with non-hip MOFs. Patients 50 years or older with distal radius or humerus fractures were included. Patients under 50 years and hip fractures were excluded. Age- and sex-based FRAX multipliers for acute distal radius and proximal humerus fractures were used to adjust FRAX scores (McCloskey et al. 2021). Low, intermediate, and high-risk of MOF was defined as less than 10%, 10-20%, and greater than 20%, respectively. Paired sample t-tests were used to compare FRAX score pre- and post-modifier. Results: A total of 142 patients, with a mean age of 65 years were included. Most patients were female (90.1%), with 75.4% sustaining distal radius fractures and 24.6% sustaining proximal humerus fractures. In the distal radius group, average MOF risk pre- and post-multiplier was 17.2 and 21.0, respectively ($p<0.05$). Seventeen percent of patients in the distal radius group moved from intermediate to high-risk after multiplier adjustment. Average FRAX scores pre- and post-adjustment in the proximal humerus group were 16.1 and 23.0, respectively ($p<0.01$), with 28.6% moving from intermediate to high-risk. Conclusion: This study demonstrates the clinically significant impact of modified FRAX scores in patients with recent fragility fractures. Seventeen percent of the distal radius group and 28% of the humerus group moved from intermediate to high MOF risk post-multiplier. Consequently, patients previously ineligible for pharmacologic management, now met criteria. Multiplier-adjusted FRAX scores may more accurately identify patients with imminent fracture risk, facilitating earlier risk reduction interventions.

SUN-391

Adjusting for Level-specific Trabecular Bone Score (TBS) Differences Reduces FRAX®-based Treatment Reclassification in Patients with Vertebral Exclusions Due to Structural Artifact: The Manitoba BMD Registry *William Leslie[1], Heenam Goel[2], Neil Binkley[3], Eugene McCloskey[4], Didier Hans[5]. [1]University of Manitoba, Canada. [2]CentraCare, St. Cloud, United States. [3]University of Wisconsin, Madison, United States. [4]University of Sheffield, United Kingdom. [5]Lausanne University Hospital & University of Lausanne, Switzerland

L1-L4 trabecular bone score (TBS) is a FRAX®-independent risk factor for fracture. Lumbar vertebrae affected by structural artifact are usually excluded from BMD measurement; how such exclusions affect TBS is uncertain. Since TBS values increase from cranial

to caudal, excluding lower vertebral levels reduces TBS and conversely increases TBS when upper lumbar vertebral levels are excluded. This can affect FRAX-based treatment when close to an intervention threshold.AIM: To examine the effect of adjusting for level-specific TBS differences in individuals with vertebral exclusions due to structural artifact on TBS-adjusted FRAX-based treatment recommendations.METHODS: We identified 71,209 individuals (mean age 64 years, 89.8% female) undergoing baseline TBS and FRAX calculations through the Manitoba Bone Density Program, where structural artifact resulting in vertebral exclusions was carefully ascertained. We compared FRAX-based treatment recommendations from the American Association of Clinical Endocrinologists (AACE) for TBSL1-L4 and from the non-excluded vertebral levels before and after adjusting TBS for mean level-specific differences.RESULTS: We computed mean differences between TBSL1-L4 and individual lumbar vertebrae in the 46,781 individuals without vertebral exclusions: L1 (+0.096), L2 (+0.008), L3 (-0.058) and L4 (-0.046). In the 24,428 individuals with vertebral exclusions, adjusting TBS using these level-specific factors gave excellent agreement with TBSL1-L4 (mean difference -0.001). Among those with baseline MOF risk >15%, TBS vertebral exclusions reclassified FRAX-based treatment in 10.6% of individuals compared with TBSL1-L4, whereas this was reduced to 7.2% after adjusting for level-specific differences (Figure). In 11,131 patients where L1-L2 was used for BMD reporting (the most common exclusion pattern with the largest TBS effect), treatment reclassification was reduced from 13.9% to 2.4%, respectively. Among individuals with baseline hip fracture risk >2%, TBS vertebral exclusions reclassified 7.1% compared with TBSL1-L4, but only 4.5% after adjusting for level-specific differences. When L1-L2 was used for BMD reporting, treatment reclassification from hip fracture risk was reduced from 9.2% to 5.2%.CONCLUSION: TBS and FRAX-based treatment recommendations are affected by vertebral level exclusions for structural artifact. Adjusting for level-specific differences in TBS reduces reclassification in FRAX-based treatment recommendations.

BONEcheck: a digital tool for personalized fracture risk assessment *Dinh Tan Nguyen[1], Thao P. Ho-Le[2], Liem Pham[3], Vinh P. Ho-Van[4], TIen Dat Hoang[4], Thach Tran[5], Tuan Nguyen[6]. [1]University of Technology Sydney, . [2]School of Biomedical Engineering, University of Technology, Sydney, Australia., Australia. [3]Saigon Precision Medicine Research Center, Saigon, Vietnam, Viet Nam. [4]Faculty of Engineering and Information Technology, Hatinh University, Hatinh, Vietnam, Viet Nam. [5]Garvan Institute of Medical Research, Australia. [6]University of Technology Sydney , Australia

Background and Aim: Osteoporotic fracture is a significant public health burden associated with increased mortality risk and substantial healthcare costs. Accurate and early identification of high-risk individuals and mitigation of their risks is a core part of the treatment and prevention of fractures. We aimed to introduce a digital tool called 'BONEcheck' for personalized bone health assessment. Methods: The development of BONEcheck primarily utilized data from the prospective population-based Dubbo Osteoporosis Epidemiology Study and the Danish Nationwide Registry. BONEcheck has 3 modules: input data, risk estimates, and risk context. Input variables include age, gender, prior fracture, fall incidence, bone mineral density (BMD), comorbidities, and genetic variants associated with BMD. By utilizing published methodologies, BONEcheck generates output related to the likelihood of fracture and its associated outcomes. The vocabulary utilized to convey risk estimation and management is tailored to individuals with a reading proficiency at level 8 or above. Results: The tool is designed for men and women aged 50 years and older who either have or have not sustained a fracture. Based on the input variables, BONEcheck estimates the probability of any fragility and hip fracture within 5 years, skeletal age, subsequent fracture, genetic risk score, and recommended interval for repeating BMD. The probability of fracture is shown in both numeric and human icon array formats. The risk is also presented in the context of treatment and management options based on Australian guidelines. Skeletal age was estimated as the sum of chronological age and years of life lost due to a fracture or exposure to risk factors that elevate mortality risk. In its entirety, BONEcheck is a system of algorithms translated into a single platform for personalized osteoporosis and fracture risk assessment. Conclusions: BONEcheck is a new system of algorithms that aims to offer not only fracture risk probability but also contextualize the efficacy of anti-fracture measures concerning the survival benefits. The tool can enable doctors and patients to engage in well-informed discussions and make decisions based on the patient's risk profile. Public access to BONEcheck is available via website https://bonecheck.org and in Apple Store (iOS) and Google Play (Android).

Nine-year survival after intertrochanteric fracture in elderly with chronic kidney disease *Ong-art Phruetthiphat[1], Attaporn Lawanprasert[2], Yodhathai Satravaha[3], Thawee Songpatanasilp[1], Chatlert Pongchaiyakul[4]. [1]Phramongkutklao Hospital , Thailand. [2]Chulabhorn hospital, Thailand. [3]Department of Orthodontics, Faculty of Dentistry, Mahidol University, Thailand. [4]Faculty of Medicine, Khon Kaen University, Thailand

BackgroundOsteoporotic hip fracture is becoming the world's major health issue as the majority of population ages [1,2]. Previous literatures demonstrated that older age, male gender, co-morbidities such as liver diseases, chronic kidney disease, heart pathology and Charlson index more than 2 were associated with increased mortality [3-7]. However, lack of data demonstrated the long-term survivors of elderly hip fracture combining with CKD. The primary outcome of this study was to identify long-term survivors of hip fracture in each stage of CKD. Secondary outcome was to demonstrate the risk factors associated with the survivors after hip fracture combined with CKD.Study Design & MethodsAfter IRB Approval, 443 intertrochanteric fractures over 60 years were recruited in this study. Patients' demography,comorbidity and mortalitywere collected.The study categorized patients into non-CKD (chronic kidney disease) and CKD groups. The former group (Stage 1; n = 39) was defined as those patients with a glomerular filtration rate (GFR) of at least 90 mL per minute (ml/min), while the other group was GFR less than 90 ml/min (n = 404). Furthermore, dividing into five subgroups by CKD groups (Stage 2, 3a, 3b, 4, and 5). The overall survivors from 1 year to 9 years were identified after PFNA fixation for intertrochanteric fractures as shown in table 1 and figure 1. We further compared the short to long term survival time in-

cluding the median survival time of hip fracture patients over 60 years in each stage of CKD as demonstrated in table 2 and figure 2. In addition, the regression analysis was performed to identify the association of risk factors and one year mortality as illustrated in table 3.ResultsThe survival rate after surgery was 89.6% at 1 year, 74.1% at 3 years, 59.9% at 5 years, and 37.8% at 9 years. Although CKD was not significantly increased the mortality (p=0.072), the Kaplan-Meier curve was significantly different (p <0.001) in each CKD stage especially in CKD 5 (Figure 1). In addition, the incidence rate of mortality was highest in CKD 5 (17.4%) and the median survival time in CKD 5 was 3.3 years. Multivariate regression analysis identified that heart disease, operative time more than 60 minutes, pulmonary embolism, poor to fair functional outcome (HHS) were significantly increased mortality.ConclusionsCKD stage 5 is associated with the highest mortality rate during short term period and the shortest median time of survival in mid to long-term period. In addition, heart disease, longer operative time, pulmonary embolism, and poor to fair HHS were associated with increased mortality. This vulnerable group required intensive care in all follow up periods

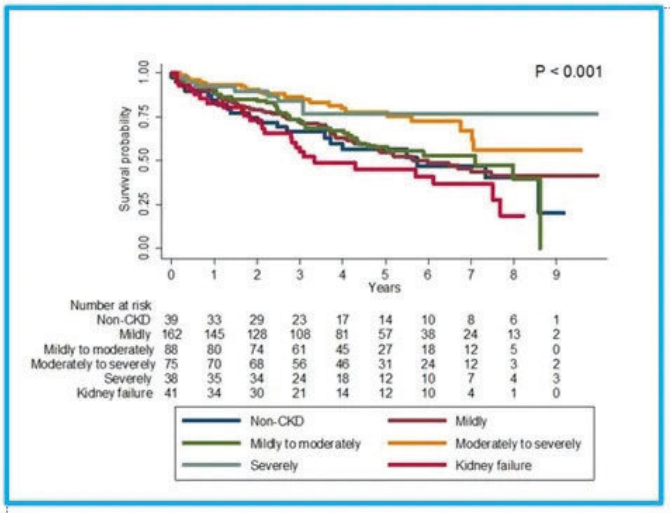

Figure 2 The comparison the survivors among each stage of CKD after hip fracture from 1 to 9 years

Dentists' Perspective on Osteoporosis Therapy: A Pilot Survey Study
*Sudhaker Rao[1], Vivek Bhan[2], Rebecca Simon[3]. [1]Henry Ford Hospital, United States. [2]Michigan State University, United States. [3]Henry Ford Health System, United States

Osteoporotic fractures are a major public health problem worldwide. Effective therapies have been available since 1995 with bisphosphonates (BPs) as the most commonly used first line drugs. However, long term BP related rare osteonecrosis of the jaw (ONJ), which may occur after dental procedures or in some cases spontaneously, has become a major barrier in initiating or interruption in therapy. The estimated incidence rate of ONJ is quite low; <0.01%in patients taking oral and 1-10% taking IV BPs. Although the risk of ONJ is low, many dentists require "clearance" for invasive dental procedures and often request "drug holiday" to avoid ONJ. There are no recommendations for such practices by the American Dental Association. In this pilot study we aimed to determine the dentist's perception and practice pattern to mitigate ONJ.After approval from Institutional Review Board, we e-mailed an online 7-point survey questionnaire to licensed dental practitioners who are members of the Michigan Dental Society (MDA) to ascertain the range of approaches dentists would take to treat patients who were using OP medications. Only registered members of the MDA were surveyed to ensure the integrity of the data being collected. A second reminder email was sent 4 weeks and the survey was closed 2 months after the initial mailing.Of the total 4808 members emailed, 30 dentists completed the survey. Respondents were 50% female and 20 worked in suburban area, 6 in urban, and 4 in rural area. 57% of the dentists have been practicing for >20y, 9 for 5-20y, and 4 for <5y. When asked about interruption of OP medications for low-risk dental procedures such as cavities; 73% never stopped therapy, 13% stopped in certain scenarios, and 13% reported stopping after discussion with patient's provider. When asked about interruption of OP medications for high-risk dental procedures (tooth extractions), 83% would interrupt therapy, 20% would interrupt in certain scenarios, 3% would always interrupt therapy, and 60% would interrupt therapy after discussion with patient's provider.Despite the rarity of ONJ and no specific guidelines from the ADA, this small pilot survey on practice patterns of dentists in Michigan is a barrier to an effective therapy to reduce the burden of a major public health problem. The responses indicate an urgent need for education of our dentist colleagues on the rationale and validity of interrupting OP therapy.

Automated Deep Learning-based CT-Scout View Assessment of Prevalent Vertebral Fractures
*Eren Bora Yilmaz[1], Till Yannik Fricke[2], Claus-C Glueer[3], Carsten Meyer[2]. [1]Christian-Albrechts-Universität Kiel , . [2]Ostfalia University of Applied Sciences, Germany. [3]Christian Albrechts Universitaet zu Kiel, Germany

Automated detection and grading of vertebral fracture status on computed tomography (CT) scout scans using artificial intelligence (AI) may be useful for both diagnosis and opportunistic prognostic evaluation of fracture risk (no added radiation dose). 2D localizer images (scout scans) taken as part of a CT protocol to select the scan range usually cover a larger area of the spine than the final 3D CT volume and thus may provide more comprehensive information on prevalent vertebral fractures, a key risk factor for future fracture. Aim: To develop and test an AI tool for classification and grading of fractures on CT scout scans. Method: "fNet" is a deep CNN that was previously applied to 3D CT volumes (Yilmaz et al., 2023) and was modified to work with 2D scout scans. It was used to classify the fracture status of individual vertebrae based on 2D image patches centered on vertebral bodies (47 × 47 mm at 1 mm/px) that were extracted using ground truth vertebral body center coordinates. The model was trained on scout scans from the Diagnostik Bilanz dataset (147 scout scans from 7 centers, 1798 vertebrae, 127 fractured, 101 with fracture grade>=2, 32 with grade 3). Ground truth (vertebral body center coordinates and per-vertebra fracture status) for T4-L4 was previously annotated by a trained radiologist using slices of 3D CT volumes. Experiments were conducted in a 4-fold cross-validation setting also used to compute mean confidence intervals (noted +/- in the following). Results: For classifying osteoporotic fractures (positive class; Genant SQ grades 1 - 3) versus normal vertebrae (negative class; Genant SQ grade 0 and deformities), the model achieved 90.6%+/-1.5% ROC-AUC. At a classification threshold of ?=0.05 the sensitivity was 81%+/-4%, the specificity 86%+/-1.3%. When regarding Genant SQ grades 2 and 3 as positive class, ROC-AUC, sensitivity and specificity (?=0.05) were 91.5%+/-0.8%, 85%+/-2% and 85%+/-1.0%, respectively. Finally, with only SQ grade 3 as positive class, we obtained 95.9% 0.8%, 87%+/-7% and 90.6%+/-0.8%, respectively. Discussion: In previous experiments on 3D CT volumes instead of scout scans we reported AUC=98.4%+/-0.4%for the classification of "0-1 vs 2-3". 2D vs 3D differences and image quality of the scout scans could be reasons for lower AUC. Conclusion: To our knowledge this is the first automatic vertebral fracture assessment method on CT scout scans. We demonstrated robust classification performance across three fracture classification tasks.

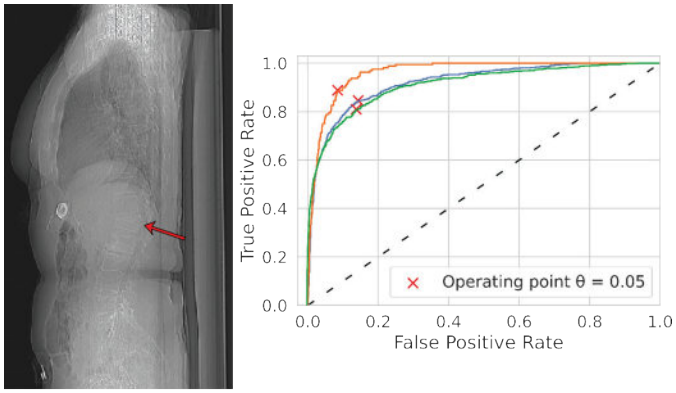

Figure: Vertebral fracture detection on CT scout scans. Left: Arrow indicates indicates Genant SQ grade 3 fracture fracture that was correctly detected by the model. Right: ROC-Curves for binary classifications of fracture grades "0 vs 1-3" (green line), "0-1 vs 2-3" (blue line), and "0-2 vs 3" (orange).

Empowering Egyptian Postmenopausal Women: A Novel Decision Tree-Based Osteoporosis Screening Tool with High Sensitivity and Predictive Value
*Abdulhafez Selim[1], Marina Dangelo[1], Sahar Ghoname[2], Paula Karabelas[3]. [1]PCOM, United States. [2]Ain Shams University School of Medicine, Egypt. [3]Independent Investigator, United States

Osteoporosis remains a significant public health concern in Egypt, particularly among postmenopausal women, necessitating the development of new, effective screening tools for prompt diagnosis. This study constructs and validates an osteoporosis screening tool based on a decision tree (DT) model. Four DT algorithms, namely, classification and regression tree; chi-squared automatic interaction detection (CHAID); quick, unbiased, efficient statistical tree; and C4.5, were applied to 395 patients, of whom 286 were abnormal and

109 normal. The investigation revealed that the DT algorithms have insignificantly different performances concerning accuracy, sensitivity, specificity, and area under the curve. Each algorithm possesses its unique performance. The Decision Tree for Postmenopausal Osteoporosis Screening (DTPOS) tool was developed from the best performance of CHAID's algorithms. The age of 58 years and a BMI cutoff of 22.1 were the crucial predictors of our tool. DTPOS provides a sensitivity of 91.3% and a positive predictive value of 81.8%, which may be used to identify subjects at risk of osteopenia and osteoporosis in community-based screening since it is simple to administer.

Establishing Japanese Osteoporosis Equivalent Vertebral Strength using Biomechanical CT (E-JOS Vertebral Study) *Junta Mawatari[1], Taro Mawatari[1], David Lee[2], Shoji Baba[1], Satoshi Hagio[1], Koichiro Kawano[1], Reima Sueda[1], Satoru Harada[1], Yasuharu Nakashima[3], Tony Keaveny[2]. [1]KKR Hamanomachi Hospital, Japan. [2]O.N. Diagnostics, LLC, United States. [3]Kyushu University, Japan

Purpose: The purpose of this study was to establish osteoporosis equivalent vertebral bone strength using biomechanical CT in a Japanese cohort and to investigate the differences in bone strength between Japanese and American women. Methods: A total of 120 female patients aged 55-90 years who underwent CT scans including the lumbar spine and bone mineral density within 3 months before and after the CT scan were randomly selected up to 20 patients in each 5-year age group. The study was single-center, retrospective in design, and used anonymized CT data analyzed with biomechanical CT. Results and Discussion: This cohort does not deviate significantly from the Japanese standard in terms of bone mineral density. The correlation between vertebral strength and bone density by DXA in women was strong (R2 = 0.81). However, most of the DXA examinations were taken at L2-L4 and did not include L1, which was judged to be unsuitable for determining the vertebral strength reference value in this study from the viewpoint of consistency with past data and the influence of posterior vertebral elements and degeneration. Therefore, the osteoporosis equivalent vertebral strength and osteopenia equivalent vertebral strength of Japanese patients were calculated from the volumetric density of L1 on CT images. The strength thresholds for Japanese women were 4,000N and 5,500N for osteoporosis-equivalent and osteopenia-equivalent vertebral strength, respectively. These values were 500N lower than the reported values for American women. In addition, the decrease in vertebral strength was greater than the rate of decrease over time in bone mineral density in the spine, femoral neck, and total hip. Conclusion: This study established osteoporosis equivalent vertebral strength using biomechanical CT in a Japanese cohort. The results showed lower values of osteoporosis equivalent vertebral bone strength in Japanese women compared to American women, highlighting the need for tailor-made medical care that comprehensively takes height, weight, and bone strength into account. The study suggests that a separate standard for osteoporosis diagnosis and treatment should be established for Japanese women based on their unique physical characteristics.

Associations Between Weight, Bone Mineral Density And Bone Marrow Adipose Tissue In Older Women and Men With Obesity *Joshua Stapleton[1], Katelyn Greene[2], Delanie Lynch[2], Denise Houston[3], Ashley Weaver[4]. [1], [2]Wake Forest School of Medicine, [3]Wake Forest University School of Medicine, Department of Gerontology & Geriatric Medicine, United States. [4]Wake Forest University, United States

Bone mineral density (BMD) and bone marrow adipose tissue (BMAT) are common metrics for the assessment of bone health and fracture risk in older adults and could be associated with changes in weight. This study measured volumetric BMD (vBMD) and BMAT from dual energy computed tomography (DECT) of older adults with obesity undergoing an active weight loss intervention to investigate baseline and 6-month change associations between weight, vBMD and BMAT.DECT scans were collected at baseline (n=186) and 6-month follow-up (n=163) in older adults (mean+/-SD: age 71.6+/-4 yrs; BMI 34.3+/-4.2 kg/m2, 65% women, 74% white) participating in the UPLIFT trial (NCT03074643; NCT03819478), a 6-month caloric restriction and aerobic exercise intervention targeting ~10% weight loss. Participants received DECT scans (140 and 80 kvp) of the lumbar spine using a Mindways Model 3 calibration phantom as the standard reference for vBMD and BMAT quantification. Scans of the L2 vertebra were analyzed using QCTPro™ software (Fig 1A,B) to calculate vBMD and BMAT fraction at baseline and 6 months. vBMD was calculated from the 140 kvp CT, while BMAT was calculated using DECT and material projection of known yellow and red marrow references. Unadjusted Pearson correlation was used for regression of outcome by sex.At baseline, BMAT (mean+/-SD: 40+/-28%) was negatively associated with weight in men (R= -0.4, p<0.01) and women (R= -0.41, p<0.01; Fig 1C); however, vBMD (105+/-43 mg/cm3) was not in men (R=0.16, p=0.29) or women (R=0.18, p=0.09). Over 6 months, body weight decreased by 8% (7.9+/-5.2 kg, p<0.01), which was negatively associated with vBMD change in women (R= -0.22, p=0.04;), but not vBMD change in men (R= -0.19, p=0.22; Fig 1D), or BMAT change in men (R=0.05,p=0.72) or women (R=0.01, p=0.92). At baseline, vBMD was negatively associated with BMAT in women (R= -0.31, p<0.01) and men (R= -0.35, p=0.02). At 6 months, changes in vBMD and BMAT were negatively associated in women (R= -0.27, p=0.01), and men (R= -0.28, p=0.06; Fig 1E).This study used DECT scans to explore cross-sectional and longitudinal associations between lumbar vBMD and marrow adiposity with obesity and weight loss. Baseline weight likely plays a significant role in BMAT fraction in the spine. Spine BMD loss was associated with marrow adiposity gains in older adults with obesity undergoing weight loss over 6 months. Results suggest a dynamic relationship between BMD and BMAT in the context of obesity and weight loss.

Body composition by DXA in the prediction of 10-years incident fragility fractures: The OsteoLaus Cohort *Colin Vendrami[1], Enisa Shevroja[1], Elena Gonzalez Rodriguez[1], Guillaume Gatineau[1], Didier Hans[1], Olivier Lamy[2]. [1]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, CHUV, Lausanne, Switzerland, Switzerland. [2]Internal Medicine Unit, Internal Medicine Department, CHUV, Lausanne, Switzerland, Switzerland

Background: Half of fragility fractures occurs in patients with normal bone density or medium/low estimated risk. The ability of body composition parameters to predict incident fragility fractures (IFF) remains unclear.Objectives: To analyze the association of body composition parameters by Dual-X-Ray Absorptiometry (DXA) and IFF (hip, humerus, forearm or radiologic vertebral low trauma fractures) over 10 years (y).Methods: Postmenopausal women from the OsteoLaus cohort were followed each 2.5y for 10y. We included those with body composition assessment by DXA (Hologic Discovery A) at baseline (n=1025) and the IFF for each follow-up separately. Patient's DXA values mean's differences between the IFF versus no IFF groups were compared using t-test and boxplots. The DXA parameters with significant difference between the two groups were further tested in univariate (M0) and multiple logistic regression model (M1-3) with stepwise adjustment for known covariables: age (M1), weight, height (M2), and femoral neck BMD T-Score (M3).Results: After excluding for previous glucocorticoid therapy, 995 participants remain at baseline (mean+/-standard deviation: age 62.7+/-7.6y, BMI 25.6+/-4.5kg/m2 and femoral neck T-Score -1.05+/-1.03). After 2.5y, 5y, 7.5y and 10y, 29/882 (3.2%), 82/799 (9.3%), 118/715 (14.2%) and 97/570 (14.5%) participants had one or more IFF/no IFF. Participants with IFF at 7.5y had higher (p<0.05) subtotal fat (+1660gr.), percent fat (PFAT, +1.3%), android fat (+186.3gr.), visceral fat (VFAT, +71.1gr.), and lower subtotal bone mineral density (BMD, -0.02gr/cm2). Total or appendicular lean mass did not differ between the IFF and no IFF group. Most of these results were not significant using a more conservative p-value<0.002 second to Bonferroni adjustment. In the logistic regressions, VFAT and subtotal PFAT were positively associated with IFF at 5y (M0) and VFAT at 7.5y (M0). Total BMC was negatively associated with IFF after 5y (M0,M2,M3), 7.5y (M1,M3) and 10y (M0-M2). Total BMD was negatively associated with IFF after 2.5y (M0), 5y (M0-M2), 7.5y (M0-M3) and 10y (M0-M2).Conclusions: As expected, DXA body composition parameters are not independent predictors of IFF. However, some bone and fat parameters could be involved in the fracture risk. Since IFF are complex and multifactorial event, further investigations considering time-to-event using cox regressions and a competing risk analysis are planned.

Are you a 'Crunchie™' or a 'Malteser™'? The Importance of the Use of Vernacular Language & Visual Messaging in Communication with Patients who have Osteoporosis. *Eamonn Brankin[1]. [1]NHS Lanarkshire / University of Glasgow / Glasgow Caledonian University/University of Strathclyde, United Kingdom

Are you a 'Crunchie™' or a 'Malteser™'? - The Importance of the Use of Vernacular Language and Visual Messaging in Communication to Patients with Osteoporosis.A perennial problem for all clinicians is in the accurate communication of clinical issues and descriptions of disease to patients. In describing osteoporosis and the reasons for fragility fracture risk, the challenge is in using language and visual imaging relevant to the patient to help him/her better understand the nature of osteoporosis and why this places the individual at increased risk of fragility fracture. In the UK, well known brands of chocolate sweet include the 'Crunchie™' chocolate bar and 'Maltesers™' chocolate sweets. In general patients understand the nature of these common chocolate / honeycomb sweets and how, in the former, the 'scaffolding' structure of the honeycomb is more robust and stronger, whereas, in the latter, the internal scaffolding structure is much less robust, with less inherent structural strength and so more likely to compression/damage. Over an approximate 12 month period, these descriptors were used to help explain the nature of osteoporosis and subsequent fragility fracture risk in 68 consecutive new patients at the osteoporosis clinic. In every case patients reported that they understood the analogy and felt that these descriptors were a significant help to them in understanding their disease, the reasons why they are now at risk of further fragilty fracture and why taking medication for this condition makes sense. Working with the Royal Osteoporosis Society, regular talks are given to patient groups by our osteoporosis service's clinicians and the most common memorable take home message patients report back is that he/she is now a 'Malteser'! Numerous studies have shown in the past that improved patient understanding of their disease results in better adherance to medication and improved outcomes. By using local language and the analogy of well known chocolate branding, patients' understanding of their disease is improved, which results in improved drug concordance, patient behaviour, clinical management and ultimately patient wellbeing and outcomes.

Estimating 'Skeletal Age' by Bone Loss in Elderly Men and Women *Ngoc Huynh[1], Krisel De Dios[1], Thach Tran[1], Tuan Nguyen[2]. [1]University of Technology Sydney, Australia. [2]University of Technology Sydney , Australia

Background and Aim: Skeletal Age is defined as the age of the skeleton as a result of a fracture or exposure to risk factors that elevate the risk of fracture. Higher rates of bone loss are associated with an elevated risk of both fracture and mortality. In this study, we aimed to assess the impact of bone loss on bone fragility by estimating skeletal age using bone loss in elderly men and women. Methods: We analyzed the data from the Study of Osteoporosis Fracture (SOF) and Osteoporotic Fractures in Men (MrOS) that included 9704 women and 5994 men aged 64 years and above. Bone mineral density (BMD) at the femoral neck was measured at baseline and subsequent visits. Mortality was ascertained from death certificates and hospital records. We limited the analysis to those with at least 3 BMD measurements (3848 women and 2925 men). The linear regression model was used to estimate the rate of change in BMD for each individual. The multivariable Cox's proportional hazard model was used to quantify the contribution of the rate of BMD change to mortality, adjusted for age, body mass index, smoking status, alcohol consumption, dietary calcium intake, estrogen and bisphosphonate treatment. The magnitude of the association between bone loss and mortality was then transformed into the number of years of life lost using Gompertz's law of mortality and the US life table. Skeletal age is then determined by the sum of chronological age and years of life lost. Results: In women, the average rate of change in femoral neck bone mineral density (BMD) was found to be -0.61 +/- 1.2% [mean+/-SD] per year, while in men, it was -0.16 +/- 0.9% per year. Throughout the study, 1942 women and 1949 men died. For women, each standard deviation [SD] increase in femoral neck BMD loss was linked to a 1.2-fold (95%CI, 1.1-1.3) increase in total mortality, while for men, the increase was 1.4-fold (95%CI, 1.35-1.5) after adjusting for age, baseline FNBMD, BMI, smoking and drinking status. Additionally, each SD increase in bone loss was associated with a loss of 1.9 years and 3.5 years of life in women and men, respectively. For the same rate of bone loss, men experienced a more substantial loss of years of life than women. Moreover, a 60-year-old woman with a femoral neck BMD loss of more than 2% is estimated to have a skeletal age of 63.5 years. Conclusion: In elderly men and women, excess bone loss is associated with an increased loss of years of life and accelerated bone fragility.

Second hand smoking is associated with elevated risk of fracture in community dwelling, non-smoking adults *Sung Joon Cho[1], Junyeong Ahn[1], Chul Sik Kim[2], Yumie Rhee[1], Namki Hong[1]. [1]Department of Internal Medicine, Severance Hospital, Endocrine Research Institute, Yonsei University College of Medicine, Republic of Korea. [2]Division of Endocrinology, Department of Internal Medicine, Yongin Severance Hospital, Yonsei University College of Medicine, Republic of Korea

Active smoking is widely known as an independent risk factor of various diseases. Yet, the risk of fracture in non-smokers exposed to second hand smoking is not well understood. A total of 5,089 non-smokers aged 40 to 69, who participated in the Korean Genome and Epidemiology Study (KOGES; study no. 4851-302) from 2001 to 2018, were analyzed. The participants were classified into two groups; currently exposed to second hand smoking and unexposed, with further categorization of second hand smoking exposures into three groups on the tertiles of the exposure time per week. Newly-developed fracture outcome was defined by sites based on self-reported questionnaire; overall, vertebral, hip, non-vertebral, and non-vertebral non-hip. The mean age of participants was 52 years (52.6% women). Incidence rate in second hand smoking exposed group was higher than those without exposure (incidence rate ratio 1.16, age-adjusted log rank p=0.001). Exposure to second hand smoking was associated with higher risk of fracture at overall sites (hazard ratio [HR] 1.35, p=0.004) after adjustment for age, sex, BMI, which remained robust after further adjustment for education, bone density of midshaft tibia, muscle mass, and c-reactive protein level (HR 1.28, p=0.022). Individuals at highest exposure time tertile had highest risk of fracture (HR 1.36, p=0.010) than lowest exposure tertile (HR 1.12, p=0.528) compared to non-exposed as referent, suggesting potential dose-response relationship. When fracture outcome was grouped by sites, second hand smoking showed association with elevated risk of non-vertebral (HR 1.41, p=0.003) or non-vertebral non-hip (HR 1.40, p=0.005) fractures, whereas the association was attenuated with vertebral fracture (HR 1.02, p=0.942). Second hand smoking was an independent risk factor for fracture (HR 1.28, p=0.017) after adjustment for FRAX major osteoporotic fracture probabilities. In summary, second hand smoking was associated with elevated risk of fracture in non-smoking adults, independent of clinical predictors.

Areal BMD at Baseline Predicts HR-pQCT Parameters 14 Years Later: Findings from the Osteoporotic Fractures in Men (MrOS) Study. *Lauren Carlson[1], Eric Orwoll[2], Andrew Burghardt[3], Peggy Cawthon[4], Kristine Ensrud[5], Lisa Langsetmo[6], Mary Bouxsein[7], Jane A. Cauley[8]. [1]University of Pittsburgh, United States. [2]Oregon Health & Science University, United States. [3]University of California, San Francisco, United States. [4]San Francisco Coordinating Center, United States. [5]University of Minnesota and Minneapolis VA Health Care System, United States. [6]Minneapolis VA Medical Center, United States. [7]Beth Israel Deaconess Medical Center, Harvard Medical School, United States. [8]UNIVERSITY OF PITTSBURGH, United States

Areal bone mineral density (aBMD) measured via DXA is an integrated measure of both trabecular and cortical BMD. High- resolution peripheral quantitative computed tomography (HR-pQCT), allows for a non-invasive assessment of cortical and trabecular volumetric bone mineral density (vBMD) and estimated strength by failure load. A small (n=78) cross-sectional study examined the correlation between total hip aBMD and HR-pQCT vBMD parameters taken at the same time. At the cortical bone, the resulting correlations were 0.12 and 0.24 at the radius and tibia, respectively. At the trabecular bone, the resulting correlations were 0.43 and 0.63 at the radius and tibia, respectively. The correlation between DXA total hip and failure load measured by HR-pQCT were 0.59 and 0.71 at the radius and tibia, respectively. The objective of the current study was to examine if total hip aBMD at baseline was associated with these same HR-pQCT parameters measured an average of 14 years later.A total of 2,424 community-dwelling older men aged 65 years and older at baseline participated. Hip aBMD was measured at baseline and HR-pQCT parameters, 14 years later. Total hip aBMD measurements were significantly associated with all HR-pQCT measures taken 14 years later. HR-pQCT measurements of trabecular bone were more strongly associated with aBMD (Table 1). Unadjusted Pearson correlations between total hip aBMD and trabecular vBMD at the distal radius and distal tibia were 0.51 and 0.54 ($p<0.05$), respectively. Unadjusted Pearson correlations between total hip aBMD and cortical vBMD at the distal radius and distal tibia were 0.17 and 0.22 ($p<0.05$), respectively. Total hip aBMD was also strongly associated with failure load at the distal radius and distal tibia. Unadjusted Pearson correlations were 0.52 and 0.60 ($p<0.05$). Models adjusted for age, comorbidities, race, site, quality of life, and walk speed showed total hip aBMD as a significant predictor of HR-pQCT measurements taken 14 years later.In conclusion, aBMD measurements from DXA were significantly associated with HR-pQCT measurements taken 14 years later. Trabecular vBMD and failure load measurements were more highly correlated with aBMD than cortical vBMD.

Table 1. Total Hip DXA as a Predictor of HR-pQCT Parameters

HR-pQCT Variable	Unadjusted Pearson Coefficient	Unadjusted p-value	Adjusted R-squared*	Adjusted P-value*
Distal Radius Cortical	0.17	<0.001	0.11	<0.001
Distal Tibia Cortical	0.22	<0.001	0.14	<0.001
Distal Radius Trabecular	0.51	<0.001	0.28	<0.001
Distal Tibia Trabecular	0.54	<0.001	0.34	<0.001
Distal Radius Failure Load	0.52	<0.001	0.30	<0.001

Effect of Race/Ethnicity on United States FRAX Calculations and Treatment Qualification: A Registry-Based Study *William Leslie[1,] [1]University of Manitoba, Canada

Since 2008 the United States has had four race/ethnic FRAX® calculators: White ("Caucasian"), Black, Asian, and Hispanic. The ASBMR Task Force on "Clinical Algorithms for Fracture Risk" has been examining the implications of retaining race/ethnicity in the US FRAX calculators.AIM: To compare treatment qualification based upon existing US FRAX race/ethnicity calculators and a hypothetical US population-based FRAX calculator. METHODS: The study sample consisted of all DXA assessments in Manitoba women aged 50 years or older from 1996-2018, with at least one year of prior coverage to assess FRAX inputs. Race/ethnicity was self-identified (119,243 White, 485 Black, 2,816 Asian, insufficient Hispanic for analysis). We computed FRAX scores according to each US calculator and the proportion exceeding intervention cutoffs (>20% for major osteoporotic fracture, MOF; >3% hip for fracture, and combined with prior fracture and T-score criteria as per the Bone Health and Osteoporosis Foundation, BHOF). We then estimated these measures for a hypothetical population-based FRAX calculator derived as the weighted mean for the US population based upon current US Census Bureau statistics.RESULTS: With identical inputs, the highest FRAX measurements were seen with the White FRAX calculator, lowest measurements with the Black calculator, with intermediate measurements for the Asian and Hispanic calculators. The percentage of women with FRAX scores exceeding the hip fracture treatment threshold was 32.0% for White, 1.9% for Black and 19.7% for Asian women; the MOF treatment threshold was exceeded for 14.9% of White, 0.0% of Black, and 3.5% of Asian women. Disparities in treatment qualification were reduced when additional BHOF criteria including DXA T-score were considered. When fracture risk was recalculated for non-White women using the White FRAX calculator, mean values for Asian women slightly exceeded those for White women but for Black women remained substantially below those for White women. When using a single population-based FRAX calculator for non-White women the mean probability of fracture and treatment qualification increased across the age range, and for Asian women slightly exceeded that for White women.CONCLUSION: Use of a single population-based FRAX calculator, rather than existing US race/ethnic FRAX calculators, will reduce differences in treatment qualification and may ultimately enhance equity and access to osteoporosis treatment.

Proportion of women with high fracture risk according to self-reported race/ethnicity using race/ethnicity-concordant FRAX calculator and population-based FRAX calculator.

Trajectories of Areal Bone Mineral Density Significantly Differ by Patterning of Femoral Neck Area and Bone Mineral Content Across the Menopausal Transition *Aleda Leis[1,] Karl Jepsen[1,] Kerry Richards-McCullough[2,] Tom Richards[2,] ERIN BIGELOW[3,] Robert Goulet[4,] Carrie Karvonen-Gutierrez[5,] [1]University of Michigan, United States, [2]University of Michigan , United States, [3]UNIVERSITY OF MICHIGAN, United States, [4]Michigan Medicine, University of Michigan, United States, [5], United States

Clinical use of areal bone mineral density (aBMD) to identify individuals at risk of fracturing assumes that aBMD change reflects bone mineral content (BMC) change. However, differences in the rate and magnitude of BMC and bone area changes over time may affect the reliability of aBMD. Understanding how different trajectories of BMC and area affect aBMD is thus central to improving our use of DXA measures to monitor bone health. This study examined the differential impact of BMC and area trajectories across the menopausal transition (MT) on aBMD. The Michigan Bone Health and Metabolism Study (MBHMS) is a longitudinal study of women; participants aged 24-50 were recruited in 1992 and followed near-annually through 2010. Femoral neck bone data were assessed using DXA. The sample included 138 women with an observed non-surgical final menstrual period (FMP); a DXA scan 10 years prior to FMP; and at least one post-FMP DXA. Group-based growth trajectory modeling was used to determine trajectory groups of area and BMC. Smoothed loess curves were constructed to examine trajectories of aBMD within each area (lowest, middle, highest) and BMC (slowest decline, moderate decline, and fastest decline) trajectory combination. Cross-tabulations of area and BMC trajectory group showed very few individuals in both the BMC fastest decline trajectory group and the area lowest trajectory group, and in the BMC slowest decline trajectory group and area highest trajectory group. The most common combinations were lowest area/slowest decline BMC (23.2%) and middle area/moderate decline BMC (21.0%). Those in the highest area/fastest decline BMC trajectory groups had the largest decline in aBMD from first to last study visit (mean 13.3% decrease, SD 8.7%; Fig. 1), while those in the highest area trajectory and the slowest BMC decline trajectory had the least decline in aBMD (mean 2.2% decrease, SD 5.9%). Understanding bone health with aging using trajectories of BMC and area change represents a novel approach to examining the significant heterogeneity across the MT, a critical life stage for musculoskeletal health. Notably, our analysis showed women who started at higher aBMD with significant BMC loss may not have been identified earlier as high risk though they show the greatest loss pattern. This information may be highly informative in identifying women at greatest risk for low aBMD and future risk for fracture.

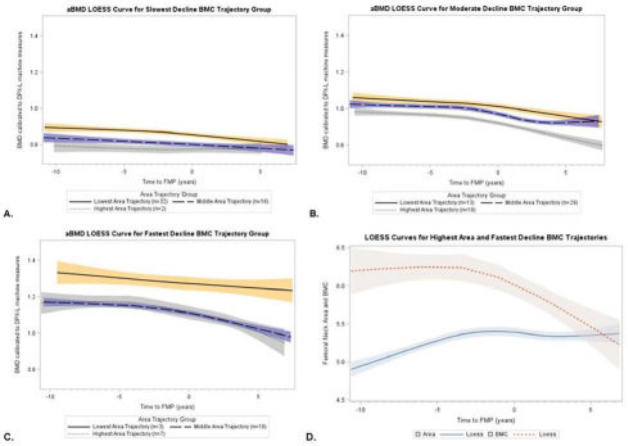

Figure 1. Loess curves for (A) aBMD by area trajectory group for those in the slowest decline BMC trajectory group, (B) aBMD by area trajectory group for those in the moderate decline BMC trajectory group, (C) aBMD by area trajectory group for those in the fastest decline BMC trajectory group, and (D) femoral neck area and BMC for those in the highest area and fastest decline BMC cross-tab trajectory group.

Rate of bone loss is associated with fracture risk: The Study of Osteoporotic Fractures *Krisel De Dios[1,] Ngoc Huynh[2,] Thach Tran[3,] Tuan Nguyen[4,] [1]University of Technology Sydney, , [2], , [3]Garvan Institute of Medical Research, Australia, [4]University of Technology Sydney , Australia

ObjectiveAlthough the link between low bone mineral density and fracture is well established, the association between aged-related bone loss and fracture remains controversial. In this study, we aimed at testing the hypothesis that excessive bone loss is associated with increased fracture risk in elderly women.MethodsThis study involved 5581 women who were a part of the Study of Osteoporotic Fractures (SOF) and had undergone a minimum of three bone mineral density (BMD) assessments. BMD at the femoral neck was measured using DXA (Hologic QDR 1000) between 1992 and 2008. The rate of BMD change was determined by utilizing a linear mixed-effects regression model. The incidence of fragility fractures (after 3 BMD measurements) was ascertained by reviewing hospital discharge records

or physician reports. Cox's proportional hazards model was utilized to assess the association between bone loss and fracture risk, while also accounting for pre-defined covariates such as BMD, age, BMI, smoking, drinking, physical activity, prior and family history of fractures. ResultsDuring the median follow-up of 13 years (IQR: 9-17), there were 1470 incident fractures, yielding fracture incidences of 25 per 1000 person-years (95% CI: 23-26). We found 679 women with a hip fracture rate of 8 per 1000 person-years (95% CI: 7-9). Bone loss was significantly associated with an increased risk of any fragility fracture (adjusted hazard ratio: 1.18; 95% CI: 1.07-1.30) and hip fracture (1.30; 95% CI: 1.13-1.50). Importantly, those with an excess annual bone loss (e.g., at least 2% per year) were associated with a 2-fold (95% CI: 1.01-4.0) increase in the risk of hip fracture.ConclusionThese data support the hypothesis that bone loss at the femoral neck is a risk factor for fracture, independent of age and baseline BMD. This suggests that repeated measurements of BMD can be useful in identifying individuals who are at high risk of fracture.

Association between a Social Determinants of Health Index and Bone Mineral Density and Odds of Osteoporosis among Puerto Rican Adults

*Liam Fouhy[1], Xiyuan Zhang[1], Kelsey Mangano[2], Bess Dawson-Hughes[3], Katherine Tucker[1], Sabrina Noel[1]. [1]University of Massachusetts Lowell, United States. [2]University of Massachusetts, Lowell, United States. [3]Tufts University, United States

Social determinants of health are known to play a key role in development of chronic conditions, however, to our knowledge, few studies have examined these factors in relation to bone health. Puerto Rican adults are at increased risk for osteoporosis, which has only recently been appreciated. Thus, it is imperative to understand whether social determinants contribute to bone health inequities in this population. This study aimed to examine the relationship between social determinants, based on a derived index, and bone mineral density (BMD), at hip and spine sites, and osteoporosis among Puerto Rican adults from the Boston Puerto Rican Osteoporosis Study. In the BPROS, there were valid data on bone mineral density (BMD) for 955 participants, using dual-energy x-ray absorptiometry (DXA). Osteoporosis at the femoral neck and/or lumbar spine was defined as T-score <= 2.5 SD below peak bone mass. Questionnaires assessing sociodemographic, perceived stress, health and health behaviors and food insecurity were administered by trained interviewers. A social determinant index was calculated by summing the values of 0 or 1 for each of the following variables: educational attainment (<8 grade), income to poverty ratio (<130% of the year specific index), marital status (married vs. not), housing stability (owned home vs. rented), perceived stress, and food security (food insecure vs. secure). A total possible score ranged from 0-7 points. General linear regression models were used for BMD outcomes and logistic regression for odds of osteoporosis. Models were adjusted for 1: age, BMI, height, and sex/estrogen status; model 2: also, for alcohol use, and smoking status; model 3: also, for serum vitamin D status. Higher social determinant scores were inversely associated with BMD at the femoral neck (?: -0.007, P=0.03), trochanter (?: -0.006, P=0.05), total hip (?: -0.008, P=0.01), and lumbar spine (?: -0.011, P=0.01). A poorer social determinant score (higher score) was associated with increased odds of osteoporosis (OR: 1.93, 95% CI: 1.13, 3.28). These results provide valuable data to inform future interventions to address bone health inequities among Puerto Rican adults living on the US mainland.

Associations of Cardiorespiratory Fitness with HR-pQCT Bone Parameters in Older Adults: The Study of Muscle, Mobility and Aging (SOMMA)

*Nina Heilmann[2], Kerri Freeland[2], Reagan Moffit[2], Nancy Glynn[2], Lauren S. Roe[3], Tong Yu[2], Nicole Sekel[2], Kristen Koltun[2], Katelyn Guerriere[4], Julie Hughes[4], Bradley Nindl[2], Ashley Weaver[5], Paolo Caserotti[6], Peggy Cawthon[7], Anne Newman[2], Jane A. Cauley[8], Elsa Strotmeyer[2]. [2]University of Pittsburgh, . [2]University of Pittsburgh, United States. [3], . [4]US Army Research Institute of Environmental Medicine, United States. [5]Wake Forest University, United States. [6]Department of Sports Science and Clinical Biomechanics and the Center for Active and Healthy Ageing, Denmark. [7]San Francisco Coordinating Center, United States. [8]UNIVERSITY OF PITTSBURGH, United States

Cardiorespiratory fitness and bone mass and strength decline with age, yet few studies have assessed the relationship of cardiorespiratory fitness with bone health in older adults. Physical activity (PA) is related to cardiorespiratory fitness and is recommended for preventing bone loss and osteoporosis. Whether cardiorespiratory fitness is associated with bone health independent of PA is unknown. The Study of Muscle, Mobility and Aging (SOMMA) included baseline assessments of VO2peak from treadmill cardiopulmonary exercise testing using the modified Balke protocol. We investigated associations of absolute VO2peak (mL/min) with bone mineral density (BMD) from dual-energy X-ray absorptiometry (DXA) and bone microarchitecture and strength from high-resolution peripheral quantitative computed tomography (HR-pQCT) collected in the SOMMA Bone Ancillary Study at the year 1 visit. In 124 men (age 76.2+/-4.3 years, 93% White) and 189 women (age 76.2+/-4.2 years, 87% White), relative VO2peak (mL/kg/min) was higher in men (23.8+/-5.5) vs. women (19.6+/-4.6; p<0.001). Bone outcomes differed between men and women (p<0.001) so analyses were stratified with sex-specific z-scores used in linear regression. Models (Table 1) were adjusted for age (years), race (White/non-White), weight (kg), >=1 alcoholic drink/week (y/n), total activity counts from valid wrist-worn accelerometry (>=3 days with >=10 h wear), comorbidity count (0-7), and limb length. In men, higher VO2peak was associated with higher tibial (standardized[std] ?=0.26, p<0.05) and radial (std ?=0.30, p<0.05) failure load, but not with DXA or other HR-pQCT parameters. Higher VO2peak was associated with higher radial trabecular (Tb) BMD (std ?=0.26, p<0.05) and cortical (Ct) area (std ?=0.25, p0.05) after adjusting for total activity. Associations were consistent when adjusting for moderate-to-vigorous PA instead of total activity counts. No significant associations were found between VO2peak and bone outcomes in women. Positive associations of VO2peak with failure load found in older men suggest cardiorespiratory fitness is associated with bone outcomes in a sex-specific manner. Future studies need to explore reasons for sex differences of VO2peak and bone outcomes.

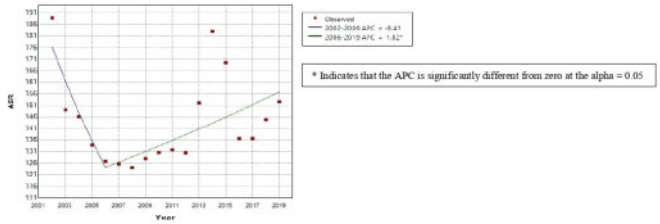
Trends in Hip Fracture Rates in Elderly Male Veterans *Amna N. Khan[1], Nabeel Khan[2], Robert B. Jones[3], Robert Adler[4], Yu Xiao Yang[2]. [1]University of Pennsylvania and Corporal Michael J Crescenz VAMC, United States. [2]Corporal Michael J Crescenz VAMC and University of Pennsylvania, United States. [3]Division of Endocrinology, University of Pennsylvania and Corporal Michael J Crescenz VAMC, United States. [4]McGuire VA Medical Center, United States

BACKGROUNDHip fractures account for about 17% of osteoporotic fractures and have the highest one-year mortality, approximately 20-30%. Half of those who survive one year post-hip fracture require assistance with ambulation and a quarter require long-term care. Hip fracture care accounts for 72% of all fracture-related medical expenses. Recent studies in Medicare health plan enrollees report that hip fracture rates may no longer be declining in women 65 years of age or older, raising concern for a widening care gap. Osteoporotic fracture has been less studied in older men, who have a poorer prognosis after hip fracture. We assessed the recent trends of hip fracture incidence in a nation-wide male veteran population older than 50 years of age.METHODSUsing data from the US Veterans Affairs Informatics and Computing Infrastructure (VINCI) 2002-2019, we calculated the annual age-standardized hip fracture incidence (standardized to the age distribution of eligible population in 2019) and analyzed the incidence trends (i.e., annual percent change [APC]) using joint point regression. As secondary objectives, we determined the annual proportion of hip fracture patients who received a) dual energy X-ray absorptiometry (DXA) before and/or after the fracture and/or b) osteoporosis medication after the hip fracture over the study period. RESULTSIn this retrospective cohort analysis of US male veterans age 50years and older, we observed a sharp but statistically non-significant decline of -8.41% APC in age-standardized hip fracture incidence between 2002-2006. However, this was followed by a statistically significant steady increase of 1.81% APC in age-standardized hip fracture incidence between 2006 and 2019.Additionally, fewer than 6% of men underwent a DXA scan one to two years after a hip fracture. Fewer than 0.5% received osteoporosis medications within 3 years prior and/or one to two years after a hip fracture during this study period.CONCLUSIONSDespite well described methods to reduce hip fractures and associated morbidity and mortality, hip fracture incidence is not decreasing in older male veterans. Our study highlights the need to pay more attention to the risk of fracture in aging men.



Age standardized rate of fractures per 100,000 veterans between 2002-2019. Annual Percent Change (APC) was calculated for each segment.

Post-Operative Outcomes among Women with Postmenopausal Osteoporosis who underwent Elective Spine Surgery: A Retrospective Cohort Study *Junjie Ma[1], Tzu-Chieh Lin[1], Tingting Gong[2], Hsu-Chih Chien[1], Brett Freedman[3], Alan Daniels[4], Kyle Mitsunaga[5], Sigurd Berven[6], John Dimar[7], Zachariah Pinter[3], Mary Oates[1], Xiaodong Li[1], Jiannong Liu[8]. [1]Amgen Inc., United States. [2]Chronic Disease Research Group, United States. [3]Department of Orthopedic Surgery, Mayo Clinic, United States. [6]Department of Neurosurgery and Orthopaedic Surgery, University of California, United States. [7]Norton Leatherman Spine Center, University of Louisville Department of Orthopedic Surgery, United States. [8]Hennepin Healthcare Research Institute, United States

BackgroundOsteoporosis (OP) is a common condition among postmenopausal women, and it may increase risk of poorer health outcomes after spine surgery. The purpose of this study is to investigate the association between history of OP and post-operative outcomes among a cohort of postmenopausal women who underwent elective spine surgery.MethodsA retrospective cohort study was conducted using the U.S. Medicare data (20% sample). Postmenopausal women who underwent elective spine surgery between January 1, 2013 and December 31, 2017 were included. History of OP was defined as having OP diagnosis, fracture diagnosis, or OP medication use before the elective spine surgery. Baseline characteristics and health outcomes during the hospitalization for the primary surgery and within 90 days and 2 years after discharge were described for patients with and without history of OP. Multivariable Cox models were used to evaluate the association between history of OP and the risk of revision surgery, fracture at any site, and death.ResultsThe study included 14,225 patients. Among them, 6,524 (45.9%) had history of OP. Patients with history of OP were older (75.3 years +/- 6.7 vs. 72.5 years +/- 5.1) and had more comorbidities (CCI: 1.4 +/- 1.7 vs. 1.1+/- 1.5) compared to those without history of OP. Among 6,524 patients with OP, 36.5% (N = 2,380) were treated with OP medication after surgery. Patients with history of OP had a higher percent of fractures and deaths during hospitalization (fractures: 2.1% vs. 1.6%; deaths: 0.35% vs. 0.14%) and within 90 days after discharge (fractures: 2.4% vs. 0.9%; death: 1.8% vs. 0.7%). A higher event rate of revision surgery, fractures, and deaths were observed within 2 years after discharge in patients with history of OP compared with those without OP. After adjusting for age, race, baseline comorbidities, and baseline medication use, Cox models showed a statistically significant association between history of OP and the risk of fractures (HR: 2.52, 95% CI: 2.21, 2.86) and death (HR: 1.54, 95% CI: 1.30, 1.83), and a marginal association between history of OP and revision surgery (HR: 1.19, 95% CI: 1.00, 1.41) after discharge.ConclusionAmong postmenopausal women who undergo elective spine surgery, a history of osteoporosis is associated with a significantly higher risk of fractures at any site and death after discharge. These findings highlight the importance of screening and appropriately treating patients for OP prior to spine surgery.

Figure 1. Post-surgery outcomes during hospitalization, and within 90 days and 2 years after discharge

Functional outcome, mortality, and risk factors in centenarian patients with hip fractures *HO YEON CHUNG[1], Byung-Woong Jang[2], Ha-Young Kim[3], Yong-Chan Ha[4]. [1]Department of Endocrinology and Metabolism, Kyung Hee University Hospital at Gangdong, Kyung Hee University College of Medicine, Republic of Korea. [2]Department of Orthopaedic Surgery, Soonchunghyang University Hospital Seoul, Republic of Korea. [3]Department of Internal Medicine, Gangneung Asan Hospital, University of Ulsan College of Medicine, Republic of Korea. [4]Department of Orthopaedic Surgery, Seoul Bumin Hospital, Republic of Korea

Introduction: Increasing longevity has caused the very old population to become the fastest-growing segment. The number of centenarians (over 100 years old) is increasing rapidly. Fractures in the elderly lead to excessive medical costs and decreased quality of life with socioeconomic burdens. However, little research has thoroughly examined the functional outcomes and mortality of hip fractures in centenarians. The purpose of this study was to 1) investigate the characteristics of hip fractures, mortality, and functional outcomes and 2) assess the risk factors for mortality in centenarians.Materials & Methods: This is a retrospective observational study. Sixty-eight centenarian hip fracture patients were admitted to the 10 institutions from February 2004 to December 2019. Fifty-six patients with 1-year follow-up were finally included. The following data were obtained: sex, age, body mass index (BMI), Charlson comorbidity index (CCI) value on the operation day, Koval's classification for ambulatory ability, type of fracture, the time interval from trauma to surgery, American Society of Anesthesiologists (ASA) grade, surgery-related complications, and duration of hospital stay. Postoperative Koval's classification (at 1-year after surgery), and information about death were also collected. Multivariate analysis was performed to analyze the risk factors affecting mortality one year after surgery.Results: Mortality rates were 26.8% at six months and 39.3% at one year. The 90-day mortality was 19.6%, and one of them (2.1%) died in the hospital. The 1-year mortality rates for the community ambulatory and non-community ambulatory groups were 29 and 52%, respectively. Only nine (16.1%)

were able to walk outdoors one year after surgery. The remaining 47 patients (83.9%) had to stay indoors after surgery. Multivariate analysis demonstrated that the pre-injury ambulatory level (adjusted hazard ratio (HR) = 2.884; p = 0.084) was associated with the risk of mortality.Conclusions: We report a 1-year mortality rate of 39.3% in centenarian patients with hip fractures. The risk factor for mortality was pre-injury ambulatory status. This could be an important consideration in the planning of treatments for centenarian hip fracture patients.

A Comparative Analysis Of Opportunistically Identified Vertebral Fractures Using CT Scans Across 4 NHS Organisations. Do Patients Survive Long Enough To Potentially Benefit From Fracture Prevention Interventions: The ADOPT study *Jack Boylan[1], Jane Turton[1], Daniel Chappell[2], Viki Sanders[2], Janine Connor[3], Rebecca Barbary[4], Elizabeth Gadd[5], Deborah Wellburn[6], Rachel Eckert[7], Alexandra Guy[6], Bilal Khan[6], Yuriy Arlachov[4], Madeline Sampson[6], Mark Baxter[6], Madhavi Vindlacheruvu[2], Elizabeth Curtis[8], Michael Stone[1], Sahota Opinder[9], Kenneth Poole[10], Muhammad Javaid[11]. [1]Bone Research Unit, Cardiff and Vale UHB, United Kingdom. [2]Cambridge University Hospitals NHS Foundation Trust, United Kingdom. [3]Bradford Teaching Hospitals NHS Foundation Trust, United Kingdom. [4]Nottingham University Hospitals NHS Trust, United Kingdom. [5]University Hospital Llandough, United Kingdom. [6]University Hospitals Southampton NHS Foundation Trust, United Kingdom. [7]University of Oxford , United Kingdom. [8]University of Southampton, UK, United Kingdom. [9]University of Nottingham , United Kingdom. [10]University of Cambridge, United Kingdom. [11]University of Oxford, United Kingdom

BACKGROUND: Vertebral fractures increase morbidity, mortality and fracture risk. Despite effective interventions, up to 70% remain undiagnosed. One recommendation for improving identification is re-reading existing CT scans that include the spine. However, these patients often have significant comorbidities. It is not clear how many patients survive long enough to potentially benefit from fracture prevention interventions.Objective: To describe survivorship of patients with vertebral fractures identified by opportunistic re-reading of existing CT scans.METHODS: Consecutive CT scans of adults aged 50 and over from 2017 that included an image of the thoracic or lumbar spine were re-read by clinicians with experience in identifying vertebral fractures using the grade 2/3 semi-quantitative Genant score in Cambridge, Cardiff, Nottingham and Southampton. Date of death was extracted from the hospital record system up to 5 years after the index CT scan. Log-rank tests were used to test for survival differences.RESULTS: 2084 consecutive scans were re-read. 50.5% were women, mean age 71.3 years. The commonest scan types were “CT Abdomen / Pelvis with contrast” (n=576) and “CT Thorax (n=356). CTPA accounted for 138 scans. 282 (13.5%) patients had a moderate or severe fracture, of whom 156 (55.3%) had died by 60 months. 28.4% had died by 12 months and 37.2% had died by 24 months. Survival was significantly shorter in those with index CTPA scans (Figure).DISCUSSION: In this audit population, most patients with vertebral fractures diagnosed using their 2017 CT scans survived more than two years. The opportunistically identified vertebral fracture population should benefit from secondary fracture prevention.

SUN-417

Sensitivity Of Modelled Fracture Liaison Service Impact To Subsequent Fracture Risk Uncertainty *Rafael Pinedo-Villanueva[1], Thierry Thomas[2], Bernard Cortet[3], JULIEN PACCOU[4], Christian Roux[5], Muhammad Javaid[1]. [1]University of Oxford, United Kingdom. [2]Hopital Nord - CHU de St-Etienne, France. [3]Service de Rhumatologie, France. [4]Lille University Hospital, France. [5], France

Purpose: Previous models of FLS impact have often used data from other countries where recent national epidemiological data are missing. We want to highlight the importance of accurate national subsequent fracture risks when estimating the benefits, resource use and budget impact of Fracture Liaison Service (FLS) implementation.Methods: A microsimulation model was run to estimate the expected impact of FLS implementation in France. It was populated by 500+ inputs characterising current practice and FLS operation in the country, and run using (1) a lower set of 10-year subsequent fracture risks obtained from stratifying and extrapolating 3-year data from the FRACTOS Study in France, and (2) a set of 10-year observed risks from Denmark which were 2.5 to 4.4 times higher (e.g. risk of spine fracture after hip fracture for women = 1.4% vs. 4.7%). Patient benefit was measured in subsequent fractures avoided and quality of life gained; resource use in hospital bed days, surgeries, clinic consultations, temporary rehabilitation days, and patient-years of institutional social care; and budget impact in health and social care costs. The model was run for the yearly 396,700 patients aged 50 years or older who have a fragility fracture in France and produced results for the first 5 years of FLS implementation. Results using each set of risks were compared to measure the sensitivity of modelled FLS impact to the different levels of fracture risk.Results: All FLS patient benefit, resource use savings, and cost savings were 3 to 4 times higher when the simulation was run using the higher risks from Demark compared to the lower estimated rates from France (see Table 1). For example, fractures avoided over 5 years were estimated at 8,972 under the higher risk set instead of 2,783 under lower risk set, and quality-adjusted life years (QALY) gain at 7,173 compared to 2,066, respectively. Savings were also 3 to 4-times higher under the higher risk set, however new investment for the expected FLS operation was only 10% higher (€307.2 vs €269.8 million) leading to a much more favourable cost-effectiveness ratio under the higher risk set (€36,196 vs. €124,366 / QALY).Conclusions: Models simulating the impact of FLS are highly sensitive to subsequent fracture risks, hence estimates informing policy implementation must use accurate national values that lead to more precise estimates of patient benefit, resource use, budget impact, and cost-effectiveness.

Table 1 - Expected FLS patient benefit and budget impact under two levels of 5-year subsequent fracture rates

	Lower rates	Higher rates	Ratio
Patient benefit			
Fractures avoided	2,783	8,972	3.2
QALYs gained	2,066	7,173	3.5
Resource use (avoided)			
Hospital bed days	16,310	51,696	3.2
Surgical procedures	1,880	5,965	3.2
Clinic consultations	8,671	27,365	3.2
Temporary rehabilitation days	11,920	38,443	3.2
Institutional social care (patient-years)	129	563	4.4
Cost savings			
Healthcare (€)	9,439,408	29,868,719	3.2
Social care (€)	4,682,505	19,015,394	4.1
FLS new investment			
Extra staff, DXA, lab, drug costs (€)	269,760,926	307,196,986	1.1

SUN-418

Fall Injury Associations with Fall-Risk Increasing Drugs (FRID) Use in Older Black and White Men and Women: the Health, Aging and Body Composition Study *Jimmie Roberts[1], Kerri Freeland[2], Lingshu Xue[2], Kristine Ruppert[2], Jeanine Buchanich[2], Jennifer Pruskowski[2], Jane A. Cauley[3], Elsa Strotmeyer[2]. [1]University of Pittsburgh Graduate School of Public Health, . [2]University of Pittsburgh, United States. [3]UNIVERSITY OF PITTSBURGH, United States

Medications that increase fall risk, defined as fall-risk increasing drugs (FRIDs), are more often prescribed now than 20 years ago, with increases mainly due to antihypertensive, antidepressant, and anticonvulsant use. The association of FRIDs and falls has been examined in older adults, but fall injury risk is largely unknown. We hypothesized that FRID use would be associated with higher fall injury risk in 1,205 community-dwelling older Black and White adults with medication and fall data in the Health, Aging, and Body Composition Study (Health ABC; 2007-2008 clinic visit with 2 years of follow-up; 84+/-3 years; 54%

women; 35% Black). Medications used in past 30 days were brought to the visit. The Stopping Elderly Accidents, Deaths & Injuries (STEADI-Rx) definition of FRIDs included any use (yes, N=1052/no, N=153) of FRIDs in the past month: antidepressants, antipsychotics, anticonvulsants, opioids, benzodiazepines, sedative hypnotics, antihistamines, muscle relaxants, and antihypertensives. Fall injuries were self-reported every 6 months for 2 years. Those with >=1 FRID were more likely to be married, have a prior year hospital stay, lower physical activity (walking/stair climbing), higher BMI, physiologic hypertension, >=1 mg/L Cystatin-C, diabetes, higher Center for Epidemiologic Studies Depression scores, and more non-FRID medications use (all p<0.05). Of participants, 81% were taking antihypertensives (Table 1), with lower use of all other FRIDs. In chi-square analysis of FRIDs by fall injury, antidepressant (16.3% vs. 9.2%), antihistamine (5.6% vs. 2.9%), and muscle relaxant use (82.5% vs. 80.6%), respectively (all p<0.05), were higher in those with fall injury vs. no injury. FRID use (yes/no) was entered in multivariable Generalized Estimating Equations (GEE) models for repeated fall injuries over time. Adjusting for demographics, lifestyle/behavioral factors, comorbidities, and non-FRID medication count, STEADI-Rx FRID use was not associated with fall injury (AOR=0.92, 95%CI: 0.56-1.48). Results were similar for count of FRIDs and fall injuries (AOR=1.02, 95%CI: 0.93-1.12). In similarly adjusted sensitivity analysis, antihypertensive use entered separately (yes, N=976/no, N=229; AOR=1.07, 95%CI: 0.71-1.61) had no association with fall injuries, though other FRID use (yes, N = 458/no, N=747) had borderline increased fall injury risk (AOR=1.31; 95%CI: 0.98-1.75; p=0.07). Including antihypertensive use with other FRID use may impact fall injury risk.

Table 1. FRID Class Prevalence (%): Overall, for 1 FRID Medication Only, and Stratified by Fall Injury (yes/no)

Medication Classes	Overall (N=1205)	Use of 1 FRID medication only* (N=643)	Fall Injury Occurrence		
			Yes (N=252)	No (N=953)	P-value
Antidepressants, %	10.7	1.1	16.3	9.2	**0.001**
Antipsychotics, %	0.7	0	0.8	0.6	0.68
Anticonvulsants, %	6.9	0.3	7.9	6.6	0.46

Validation of the Swiss FRAX model for fracture risk assessment using 10-years fracture data from the OsteoLaus Study *Enisa Shevroja[1], Vendrami Colin[3], Elena Gonzalez Rodriguez[3], Guillaume Gatineau[4], Olivier Lamy[5], Didier Hans[4]. [1]Lausanne University Hospital, Switzerland, [3]CHUV, , [3]CHUV, Switzerland. [4]Lausanne University Hospital & University of Lausanne, Switzerland. [5]University Hospital, Switzerland

Background : FRAX provides the fragility fracture risk in the next 10 years. FRAX score threshold is currently recognized as reimbursement criteria for dual X-ray absorptiometry (DXA) acquisiton and certain osteoporosis treatments in Switzerland. Further, Swiss national guidelines recommend its use in treatment decision-making. Objectives : To investigate the FRAX performance at predicting the occurrence of incident major osteoporotic fractures (MOF) during 10 years of follow-up. Methods : 944 Swiss postmenopausal women (mean age 62.7+/-7.6y) from the OsteoLaus cohort were included in this analyses. The participants had FRAX assessed at baseline, had undergone a DXA and had incident and prevalent MOF data at baseline and 4 follow-up visits every 2.5 years, with a total follow-up period of 10 years. T-tests were used to study the difference of FRAX adjusted for clinical risk factors (CRF) and of FRAX adjusted for bone mineral density (BMD) and trabecular bone score (TBS) between fractured and non-fractured groups. FRAX sensitivity and specificity were assessed for cutoffs of 10%, 20%, and moderate and high risk age-adjusted cutoffs as recommended by the Swiss national guidelines. Results : The 10y MOF incidence in the low risk group (FRAXTBS<10%) was 10%, moderate risk (10%<FRAXTBS<20%) was 25% and high risk (FRAXTBS>20%) was 48%; and for FRAXCRF the 10y MOF incidence was 11.7%, 23% and 29%, respectively. Both FRAXCRF and FRAXTBS were significantly higher in the fractured group. The sensitivity of FRAXTBS cutoff 10% was 66%, specificity was 42%; the sensitivity of FRAXCRF cutoff 20% was 20%, specificity 7.5%. The sensitivity and specificity of the FRAXTBS age-dependent cutoff was 18% and 7%, respectively. Conclusions : The fully adjusted FRAX model, comprising adjustment for CRF, BMD and TBS performs better in fracture prediction than the only CRF adjusted model. The age-dependent FRAX cutoffs used currently in Switzerland show a low sensitivity and specificity in the 10 years fracture prediction in the OsteoLaus cohort. Further analysis will study more FRAX performance parameters; and take into account time dependent fracture occurrence and the possible effect of antiosteoporotic treatment use in FRAX performance.

Associations of Metabolic Syndrome (MetS) with Fall Rates and Fall Injuries: Results from the Objective Physical Activity and Cardiovascular Health in Older Women (OPACH) *Chen Hu[1], Kerri Freeland[1], Michael LaMonte[2], Marcia Stefanick[3], Kristine Ensrud[4], Jane Cauley[1], Andrea LaCroix[5], Elsa Strotmeyer[1]. [1]University of Pittsburgh, United States. [2]University of Buffalo, United States. [3]Stanford University, United States. [4]University of Minnesota Twin Cities, United States. [5]University of California San Diego, United States

MetS is an increasingly prevalent disorder that consists of a cluster of metabolic conditions. Previous studies found individual MetS components were associated with falls and fall injuries in older adults, though the association of MetS, as a constellation, with these outcomes is unknown. We aimed to evaluate whether MetS was associated with higher fall rates and fall injury risk among older women in a community-based cohort in the OPACH, an ancillary study of the Women's Health Initiative (WHI). Participants were 5,548 women (mean 79.0+/-6.7 years; 63.4% White; 30.8% obese) who had a blood draw and physical measurements during 2012-2013, and >1 month of fall calendars over a 13-month follow-up. MetS (Y/N) was defined as having?>=3 of 5 criteria per NCP/ATP-III guidelines: waist circumference?>88 cm, fasting glucose >=100 mg/dL or hypoglycemic medication use, systolic BP?>=130 or diastolic BP?>=85 mmHg, high-density cholesterol?<50 mg/dL, and triglycerides >=150 mg/dL. Falls and fall injuries were ascertained by monthly fall calendars and telephone interviews. Poisson regression examined MetS associations with fall rates. Weighted logistic regression was used for MetS associations with fall injuries (Y/N), while accounting for sampling strategies for interviews. MetS (N=1,125) was present in 20.3% the cohort and 43.6% (N=2,417) reported >=1 fall. Fall injuries were reported in 35.6% (508/1,428) over mean 11.9+/-2.3 mo. of follow-up. In unadjusted models, MetS was associated with 17% higher fall rates (RR=1.17, 95%CI=1.10-1.24) and 17% higher odds of fall injuries (OR=1.17, 95% CI=1.02-1.34). After adjusting for age, race (White/Black/other), ethnicity (Hispanic/non) and obesity (BMI>=30) the association persisted between MetS and fall rates (RR=1.12, 95%CI=1.04-1.20), but the association between MetS and fall injuries was attenuated to null (OR=1.08, 95%CI=0.93-1.24). In addition to MetS, obesity was an independent risk factor of higher fall rates (RR=1.16, 95%CI=1.08-1.25). Age-stratified adjusted analyses found MetS associated with higher fall injuries (OR=1.18, 95%CI=1.00-1.39) in women aged 65-85 years (N=1,159), but a non-significant inverse association (OR=0.83, 95%CI=0.57-1.10) in women aged >85 years (N=269). MetS was associated with higher fall rates in women >=65 years and injurious falls in women <85 years. Further studies should evaluate potential mechanisms of individual MetS components and how comorbidities may contribute to these associations.

Skeletal Age for mapping the impact of fracture on mortality using clinical data *Thach Tran[1], Dinh Tan Nguyen[2], Lisa Langsetmo[3], Nancy Lane[4], Tuan Nguyen[5]. [1]Garvan Institute of Medical Research, Australia. [2]University of Technology Sydney, . [3]Minneapolis VA Medical Center, United States. [4]University of California, Davis Medical Center, United States. [5]University of Technology Sydney , Australia

Fragility fracture is associated with an increased risk of mortality, though mortality is not part of patient-doctor risk communication. We used the Danish nationwide registry-based data to propose a new metric called "Skeletal Age" to convey the combined risk of fracture and fracture-related mortality for an individual. This study sought to estimate Skeletal Age for specific fracture sites using self-reported and clinically measured data.Skeletal Age is conceptually defined as the age of an individual's skeleton resulting from a fragility fracture. Thus, for an individual with a fracture associated with increased mortality risk, the skeletal age would be expected to be higher than the individual's chronological age. Skeletal Age is estimated as the sum of chronological age and the number of years of life lost (YLL) associated with each fracture site for an individual with specific risk profiles. Cox's proportional hazards model was employed to determine the hazard of mortality associated with a specific fracture for a given risk profile including age, BMD, BMI, lifestyle factors, and the presence of comorbidities, and the hazard was then transformed into YLL using the Gompertz law of mortality.The study involved 5994 community-dwelling elderly men in the Osteoporotic Fractures in Men Study (MrOS) with an average age of 73.6 (+/- 5.9) years. During a median follow-up of 13.9 years (IQR: 8.5, 17.5), 1085 men had sustained a fragility fracture followed by 694 deaths (~11.8 deaths/100 person-years). Hip, other proximal, and lower leg fractures were associated with a significantly increased risk of death. On average, a fragility fracture was associated with 1 to 9 years of life lost, with the loss being greater in younger patients with a hip, femur, or pelvis fracture. A 60-year man with a hip fracture is estimated to have a Skeletal Age of 68.1 (95% CI: 66.9, 69.2); whereas the estimated skeletal age for a 70-year man with a hip fracture is 76.3 (75.4, 77.1). Skeletal Age was also estimated for each age and specific fracture associated with increased mortality risk (Figure).Our results reemphasize that most fractures are associated with increased mortality risk and hence reduced life expectancy. The findings were consistent in both registry-based and clinical data. The proposed Skeletal Age supplements the traditional relative risk as a metric for conveying the mortality consequence of fracture, making the doctor-patient risk communication more intuitive.

SUN-424

Volumetric BMD, Failure Load, and Other HR-pQCT Measurements Are Associated with Clinical and Hip Fracture Risks: Follow-up 6.2 Years *Tong Yu[1], Elsa Strotmeyer[1], Andrew Burghardt[2], Kristine Ensrud[3], Lisa Langsetmo[4], Eric Orwoll[5], Peggy Cawthon[6], Mary Bouxsein[7], Jane Cauley[1]. [1]University of Pittsburgh, United States. [2]University of California San Francisco, United States. [3]University of Minnesota, Minneapolis VA Health Care System, United States. [4]University of Minnesota, United States. [5]Oregon Health and Science University, United States. [6]University of California San Francisco, California Pacific Medical Center, Research Institute, United States. [7]Harvard medical school, United States

Current fracture prediction relies on clinical risk factors combined with areal bone mineral density (aBMD) measurements. However, deficits in bone microstructure, measured by high resolution peripheral quantitative computed tomography (HR-pQCT), may also contribute to age-related increases in fracture risk. Previous studies have shown associations between HR-pQCT parameters and clinical fracture, but most studies did not examine hip fracture, the most devastating consequence of osteoporosis, specifically.The analytic sample included 1794 men (median 84 years) with HR-pQCT and DXA scans at Year 14 visit of MrOS. The outcomes were incident clinical fractures and hip fractures. Failure load was estimated using finite element analysis. We used Cox models with standardized HR-pQCT parameters as predictors of fracture risk, adjusting for clinical sites, limb length and total hip aBMD with clinical risk factors (CRFs) for fractures or FRAX 10-year probability of osteoporotic fractures with FN aBMD. We compared incidence rates of clinical fracture across quartiles of failure load and presence of low femoral neck (FN) aBMD by T score (<=-1) vs normal.Over 6.2 years of follow-up, 318 men had at least one incident clinical fracture, including 74 hip fractures (23%). One standard deviation (SD) decrement of total volumetric (v) BMD at distal radius was significantly associated with increased risk of clinical fracture (HR=1.44, 95%CI 1.23-1.68) and hip fracture (HR=1.84, 95%CI 1.32-2.57) after adjusting for total hip aBMD and CRFs. (Table). Results were in the same direction for failure load (HR=1.48 for clinical fracture, HR=1.69 for hip fracture). On the contrary, one SD lower of total area at distal radius was significantly associated with reduced risk of hip fracture (HR=0.55) but not clinical fractures. Adjusting for FRAX with FN aBMD instead of total hip BMD and CRFs further strengthen the associations. Associations with parameters at distal tibia are weaker than those at distal radius. Higher quartiles of distal tibia failure load and vBMD were associated with a decreasing fracture incidence rate in both normal and low FN aBMD groups.In community-dwelling older men, lower failure load and total vBMD are robust predictors for risks of clinical fractures and hip fractures. Lower total area was associated with reduced hip fracture risk. HR-pQCT parameters provide fracture prediction independent of existing fracture risk assessment tools.

Table. Estimated hazard ratios (per decrement SD) and 95% confidence intervals (CI) of volumetric BMD, total bone area and failure load for clinical fractures and hip fractures.

	Model 1[1] (Total hip aBMD + CRFs)		Model 2[2] (FRAX with FN aBMD)

Association of Serum Pentosidine with Fracture in Women from the Canadian Multicentre Osteoporosis Study *Lindsie Blencowe[1], Andrea Bozovic[2], Vathany Kulasingam[2], George Tomlinson[2], Evelyn Wong[2], Claudie Berger[3], Jerilynn Prior[6], Robert Josse[5], Brian Lentle[6], Alexandra Papaioannou[7], Suzanne Morin[8], William Leslie[9], Stephanie Kaiser[10], Christopher Kovacs[11], DAVID GOLTZMAN[8], Jonathan Adachi[12], Angela Cheung[13]. [1]University of Toronto, University Health Network, . [2]University Health Network, Canada. [3]Research Institute of the McGill University Health Center, Canada. [6]University of British Columbia, Canada. [5]St. Michael s Hospital, University of Toronto, Canada. [6]University of British Columbia, . [7]McMaster University , Canada. [8]McGill University, Canada. [9]University of Manitoba, Canada. [10]Dalhousie University, Canada. [11]Memorial University of Newfoundland, Canada. [12]St. Joseph s Hospital/McMaster University, Canada. [13]University Health Network-University of Toronto, Canada

Purpose: The glycation of bone collagen results in compounds known as advanced glycation end-products (AGEs). The accumulation of AGEs in bone has been associated with increased fracture risk. Pentosidine (PEN) is a cross-link AGE found in bone. Serum PEN has been shown to correlate with the PEN content of bone and may be a useful biomarker. Serum PEN was assessed in women participating in the Canadian Multicentre Osteoporosis Study (CaMos) to explore its association with fracture.Methods: Total serum PEN was assessed using liquid-chromatography tandem mass spectrometry in stored serum samples from 1200 women (aged 41-72 years), at year 10 in CaMos. The association between serum PEN and All Fractures (any site), Major Osteoporotic Fracture (MOF), Fragility Fracture (FF, defined as low trauma, nonvertebral fractures, excluding the head, hand and foot), Hip Fracture (HF) and Vertebral Fracture (VF, Genant Grade >1) was explored using multivariable logistic regression. We adjusted for age or estimated glomerular filtration rate (eGFR), as age and eGFR are the most significant predictors of serum PEN. Given the limited number of fractures in the cohort, we could only adjust for one covariate at a time. Serum PEN quartiles were used in the analyses to allow for non-linear associations with fracture. Our analyses explored timepoints at years 1-10 and 11-15 for All Fractures, MOF, FF, and HF and at years 10 and 16 for VF.Results: Serum PEN ranged from 0.31 to 41.0 nmol/g albumin (median 0.92 nmol/g). From years 1-10 and years 11-15 there were 250 and 176 total fractures, 87 and 55 MOF, 149 and 102 FF, 11 and 18 HF, respectively. For years 10 and 16, there were 77 and 16 VF, respectively. After Age adjustment, serum PEN was associated with FF (years 11-15) (OR: 2.12, 95% CI: 1.11-4.02), but was not associated with any other fracture outcomes or timepoints. After eGFR adjustment, the 3rd quartile serum PEN level was significantly associated with MOF and FF (years 1-10 and years 11-15) (ORs: 2.27-2.93, 95% CIs: 1.18-6.89) and was associated VF at year 10 (OR: 2.14, 95% CI: 1.03-4.48) but was not associated with All Fractures. There were too few HFs (all time points) and VFs (year 16) to be able to interpret and draw conclusions from the results.Conclusions: Our results suggest that there may be an association between serum PEN levels and fracture, particularly fragility fracture. Further exploration into the utility of serum PEN as a fracture biomarker is warranted.

Hip fracture rate and osteoporosis treatment in long-term care: Ontario Osteoporosis Strategy *Hajar AbuAlrob[1], Susan Jaglal[2], Crystal MacKay[3], Cathy Cameron[2], Yinan Li[4], Haley Golding[4], Lesley Plumptree[4], Ravi Jain[5], George Ioannidis[1], Loretta Hillier[6], Alexandra Papaioannou[1]. [1]McMaster University, Canada. [2]University of Toronto, Canada. [3]Westpark Hospital, Canada. [4]Institute for Clinical Evaluative Sciences, Canada. [5]Osteoporosis Canada , Canada. [6]Ontario Osteoporosis Strategy, Canada

Aim: This population-based study reports trends in hip fracture rates and osteoporosis treatment according to fracture risk level in long-term care (LTC) adults >=65 years from 2014/15-2018/19.Methods: Osteoporotic fracture were identified using Public Health Agency of Canada algorithm and ICD-10 codes. Health administrative data was linked using unique, encoded identifiers and analyzed at ICES. Fracture risk was determined using the Fracture Risk Scale (FRS). FRS predicts hip fracture over a 1-year period using data readily available in RAI MDS 2.0 and LTC-specific risk factors and consists of 8 risk levels (1 lowest risk, 8 highest risk).Results: There has been a 41.2% increase in the age standardized rate of hip fracture in LTC (from 223.6 per 10,000 in 2014/15 to 315.7 per 10,000 in 2018/19). The rate increased for both women (+47.0%) and men (+56.5%), adults 66-79 years (+63.8%) and 80+ years (+28.5%), and across setting (+85.6% in rural +44.7% in urban). From 2014/15 to 2018/19 the proportion of LTC residents 66+ not investigated or treated within 6 months after discharge from a hip fracture decreased from 83% to 73%. The overall rate of osteoporosis treatment among LTC residents at high-risk of fracture (Fracture Risk Scale score 4+) increased by 8.7% (23.3% in 2014/15 to 25.4% in 2018/19). Among LTC residents at high fracture risk (FRS 4+), treatment rate was higher for females than males (31.2% for women vs 11.6% for men 2018/19), adults 80+ years compared to 66-79 (19.3% for 66-79 age group, 26.3% for 80+ 2018/19), and large LTC facility size compared to small and medium (11.5% for small, 22.1% for medium, 26.2% for large, in 2018/19). Conclusion: The hip fracture rate in LTC in Ontario, Canada has increased over time, and is higher for women and seniors 80+ years. Treatment rate for LTC residents at high risk for fracture has increased over time, and treatment rate varies across age groups and LTC facility size. Residents in LTC are at very high risk for fracture and need individualized treatment. Care needs to be patient centred and individualized based on goals of care and life expectancy. Fracture Risk Scale score should be used to identify those at high risk for fracture in LTC.

SUN-427

Abaloparatide Increases Distal Femur BMD Post Total Knee Arthroplasty *Neil Binkley[1], DIANE KRUEGER[2], Gretta Borchardt[3], Brian Nickel[3], Paul Anderson[3]. [1]University of Wisconsin, Madison, United States. [2]UNIVERSITY OF WISCONSIN, United States. [3]University of Wisconsin, United States

Purpose: Osteoporosis is common in total joint replacement patients and increases risk for adverse outcomes including revision surgery and periprosthetic fracture. Existing data indicates total knee arthroplasty (TKA) leads to rapid distal femur bone loss. We hypothesized that Abaloparatide (ABL) would mitigate this loss. The purpose of this preliminary analysis is to evaluate the effect of ABL begun ~3 months prior to TKA on distal femur BMD.Methods: Female and male TKA candidates age >= 55 years were enrolled in this open-label 18-month study. Those with clinical osteoporosis, defined as T-score <= -2.5, or < -1.0 with prior low-trauma fracture, received subcutaneous ABL up to 80 mcg daily. Subjects with osteopenia but without fracture comprised the an untreated control (CON) group. BMD was measured at the lumbar spine, total hip, 0.3 radius and distal femur at screening (~3 months pre-TKA), 1 week pre-op, 6 and 15-months post-op. Distal femur BMD was measured at regions of interest (ROIs) placed at 15% and 25% of femur length. Groups were compared at baseline by t-test. For this preliminary analysis in study completers (n = 10 ABL/17 CON) BMD change at all measured sites was assess by ANOVA.Results: To this point, 27 of the planned 29 ABL subjects and all 29 controls have been recruited. Mean (SD) age and BMI did not differ between ABL and CON groups; 70.6 (7.4) vs. 68.5 (7.0) years and 31.9 (6.5) vs. 30 (4.6) kg/m2 respectively. ABL group screening BMD was lower (p <= 0.05) at all measured sites. ABL was administered for mean (SD) 89 (67) days prior to TKA. At the 15% distal femur ROI, BMD percentage change from screening was higher than control (p < 0.05) at pre-op, 6 and 15 months by 1.6%, 5.5% and 8.6% respectively. Similarly, at the 25% ROI BMD change was greater (p < 0.05) at 6 (3.6%) and 15 months (5.2%; Table). At 15 mo, spine and total hip BMD change from baseline was greater (p < 0.001) in the ABL group (9.9% and 6.3% respectively).Conclusion: In this preliminary analysis, ABL increased distal femur BMD following TKA. This increase was demonstrable with ~3 months of treatment.

Most patients on denosumab with hypocalcemia continued treatment without further hypocalcemia on follow-up *Cherie Chiang[1], Nadia Pocci[1], Jasmine Seah[1], Sharjeel Ahmad[1], Peter Mount[1]. [1]Austin Health, Australia

Impaired renal function is a known risk factor for hypocalcemia in de novo denosumab use, however the prevalence of hypocalcemia in established denosumab users with declining eGFR is unknown. We conducted a retrospective longitudinal cohort study to assess the incidence and risk factors of hypocalcemia in patients on long-term established or de novo denosumab treatment stratified by severity of kidney disease. 312 patients prescribed denosumab at Austin Health from 2016-2020 who had follow-up pathology were included. The breakdown of CKD stages at baseline was CKD 2 = 70%, CKD 3a = 20%, CKD 3b = 9%, CKD 4 = 1%, at most recent follow-up was: CKD 2 = 65%, CKD 3a = 19%, CKD 3b = 10%, CKD 4 = 6%. Hypocalcemia (any low total or corrected or ionised Ca) was found in 26% (total calcium = 2.0 +/- 0.17, corrected calcium 2.2 =+/- 0.16, iCa = 1.06 +/- 0.08 mmol/L). Compared to the normocalcemic cohort, the hypocalcemic cohort had a higher CKD stage at baseline (p = 0.015), lower eGFR (p < 0.001), lower albumin (p < 0.001), lower corrected calcium (p 1 year), hypocalcemia was present in 27% (72/263), neither recent eGFR or change in eGFR was associated with hypocalcemia. Of the 81 hypocalcemic subjects, 2 patients had hypocalcemic symptoms requiring admission, 57 continued denosumab (13/57 had eGFR < 45) and 3 patients had recurrent low corrected calcium. Of the 32 subjects with baseline eGFR < 45, 13 ceased denosumab (6 deceased, 1 declining eGFR, 3 clinician's choice, 3 no information). Of the 19 who continued denosumab (follow-up 3.3 +/- 2.4 years, recent mean eGFR 37 +/- 10), only one patient had an asymptomatic low corrected Ca of 2.0 and albumin of 23 g/L on recent pathology. In conclusion, hypocalcemia was common in de novo or established denosumab use, mostly driven by low albumin. Hospital presentations due to symptomatic hypocalcemia were rare. Hypocalcemia was not associated with magnitude of eGFR decline, most hypocalcemic patients continued denosumab without further episodes.

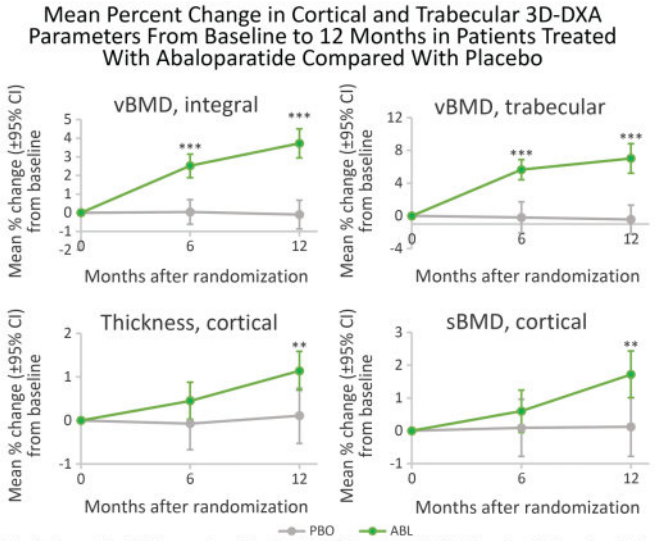
Effects of Abaloparatide on Cortical and Trabecular Compartments by 3D-DXA in Men with Osteoporosis *Ruban Dhaliwal[1], John Boxberger[2], Yamei Wang[3], Bruce Mitlak[2], Ludovic Humbert[4], Neil Binkley[5]. [1]State University of New York Upstate Medical University, . [2]Radius Health, United States. [3]Radius Health, Inc., United States. [4]3D-Shaper Medical, Spain. [5]University of Wisconsin, Madison, United States

Abaloparatide (ABL) increases bone mineral density (BMD) in men with osteoporosis. In the Abaloparatide for the Treatment of Men with Osteoporosis (ATOM) trial, DXA-measured BMD change with ABL 80 ?g/day was greater than placebo (PBO) at the lumbar spine, total hip, and femoral neck. The purpose of this study was to evaluate the effects of ABL on cortical and trabecular compartments of the proximal femur in men with osteoporosis using 3D-DXA modeling. Blinded hip DXA images from all randomized patients in the ATOM trial (n=149 ABL; n=79 PBO) were retrospectively analyzed using 3D-DXA 3D-Shaper software (v2.12.0, 3D-Shaper Medical) to evaluate changes from baseline at months 6 and 12 at the total hip. Comparisons from baseline were made using paired t tests. Between-group comparisons were made for percent change from baseline data based on a mixed-effect repeated-measure model with treatment, visit, treatment-by-visit interaction and DXA scanner as fixed effects. Other covariates include body mass index (BMI), age, and value at baseline. At 12 months, significant within group increases from baseline (P<0.0001) in integral volumetric BMD (vBMD) (3.7%), trabecular vBMD (7.0%), cortical thickness (1.1%), and cortical surface BMD (sBMD; 1.7%) were observed with ABL. Mean percent change from baseline was greater for ABL compared to PBO (P<0.01) for all 4 variables (integral vBMD, trabecular vBMD, cortical thickness, cortical sBMD) at 12 months (Figure).

Greater increases (P<0.0001) were also observed at 6 months between ABL and placebo for integral vBMD (2.5% vs 0.04%) and trabecular vBMD (5.7% vs ?0.2%). In conclusion, in men with osteoporosis in ATOM, 12 months of treatment with ABL improved cortical and trabecular 3D-DXA parameters at the total hip, consistent with the results in postmenopausal women in the ACTIVE study.



ABL, abaloparatide; BMD, bone mineral density; CI, confidence interval; PBO, placebo; sBMD, surface BMD; vBMD, volumetric BMD.

Impact of Bisphosphonate Use Following Hip Fracture: A Decade-Long Follow-Up of a Cohort Within a Private Healthcare System *Betiana Perez[1], Maria Eugenia Vera[1], Luisa Carmen Plantalech[1], Maria Diehl[1]. [1]Hospital Italiano de Buenos Aires, Argentina

Bisphosphonate use after hip fracture is useful for secondary prevention and may reduce post-fracture morbidity and mortality. Aims To evaluate the long-term impact of bisphosphonate use after hip fracture in mortality and morbidity. Methods Retrospective cohort study of patients >=50 years from a closed health system hospitalized for a fragility hip fracture between July 2005 and December 2010. Deaths and readmissions were analyzed. Kaplan Meier survival analysis and Cox regressions were performed. Sensitivity analysis with propensity score matching (PSM), considering age, sex, previous fracture and comorbidities was employed to adjust for prescription bias. Results We included 965 patients. The median age was 82.4 years (IQR 77.8-86.6), and 80.7% were female. Secondary prevention with bisphosphonates was administered to 39% of cases within the year after hip fracture. Mortality in the first year was 14.9% and at 10 years 73.2%. Median survival was 5.6 years. The median survival of patients with hip fracture treated with bisphosphonates was 8.33 years, and for those not treated it was 4.06 years (p<0.0001), and remained significantly different after PSM (p= 0.022). Median survival free of readmissions was 2.93 years; 4.02 years for treated with bisphosphonates, and 2.09 years for not treated (p<0.0001), and also remained different after PSM (p= 0.045). Multivariate Cox regression showed that secondary prevention with bisphosphonates remains an independent predictor of survival and survival free of readmissions, even after adjusting for significant covariates (table 1). Conclusions Bisphosphonates positively impacted survival and readmissions in our study after adjusting by demographic variables, comorbidities. However, we could not assess other relevant covariates such as educational level and social support.

	Mortality	Readmissions
Age (each year)	1.08(1.07-1.09) [a]	1.04 (1.03-1.05) [a]
Male sex	1.22(1.01-1.48) [b]	1.12 (0.92-1.37)
Intracapsular fracture	1.46(1.22-1.74) [a]	1.32 (1.10-1.59) [c]
Charlson Index (each point)	1.14(1.08-1.20) [a]	1.17 (1.11-1.23) [a]
Dementia	1.74(1.46-2.07) [a]	1.23 (1.03-1.48) [d]
Congestive heart failure	1.68(1.30-2.17) [a]	1.99 (1.50-2.65) [a]
Secondary prevention with bisphoshonate	0.68 (0.58-0.80) [a]	0.72 (0.61-0.86) [a]

A Randomized, Double-blind, Phase III Study to Compare SB16 (Proposed Denosumab Biosimilar) to Reference Denosumab in Patients with Postmenopausal Osteoporosis *Richard Eastell[1], Bente Langdahl[2], Yoon-Sok Chung[3], Rafal Plebanski[4], Edward Czerwinski[5], Eva Dokoupilova[6], Jerzy Supronik[7], Jan Rosa[8], Anna Rowi?ska-Osuch[9], Ki Hyun Baek[10], Audrone Urboniene[11], SoHui Ahn[12], Young Hee Rho[12], Jisuk Ban[12]. [1]University of Sheffield, United Kingdom. [2]Aarhus University Hospital, Denmark. [3]Ajou University Hospital, Republic of Korea. [4]Klinika Zdrowej Kosci, Poland. [5]Krakowskie Centrum Medyczne sp z oo, Poland. [6]MEDICAL PLUS sro; Masaryk University, Czech Republic. [7]OsteoMedic sc A Racewicz J Supronik, Poland. [8]Affidea Praha sro, Czech Republic. [9]ETG Warszawa, Poland. [10]Yeouido St Mary's Hospital, Republic of Korea. [11]JSC Saules seimos medicinos centras, Lithuania. [12]Samsung Bioepis, Republic of Korea

Introduction: SB16 is a human monoclonal antibody to the receptor activator of nuclear factor ?? ligand that has been developed as a proposed biosimilar to reference denosumab (brand name: Prolia, DEN hereafter).Objective: This Phase III study was a randomized double-blind study to compare efficacy, safety, pharmacokinetics (PK), pharmacodynamics (PD) and immunogenicity of SB16 with DEN in postmenopausal osteoporosis (PMO) patients (NCT04664959). Results up to Month 12 are presented here.Methods: PMO patients were randomized in a 1:1 ratio to receive either 60 mg of SB16 or DEN subcutaneously at Month 0, Month 6, and Month 12. At Month 12, patients in DEN were re-randomized in a 1:1 ratio to switch to SB16 or maintain DEN. The primary endpoint was percent (%) change from baseline in lumbar spine bone mineral density (BMD) at Month 12. Equivalence between SB16 and DEN was declared if the 95% confidence interval (CI) of least squares means (LSMeans) difference of % change in lumbar spine BMD at Month 12 was within the pre-defined equivalence margin. Other secondary efficacy, PD (serum C-telopeptide of type I collagen [CTX] and procollagen type I N-terminal propeptide [P1NP]), PK and safety endpoints were also measured.Results: Among 457 patients, 225 patients were randomized to SB16 and 232 patients to DEN. Baseline characteristics were comparable between SB16 and DEN. The mean % change from baseline in lumbar spine BMD at Month 12 was 5.6% and 5.3% in SB16 and DEN, respectively (Figure 1), and the difference in LSMeans was 0.39, 95% CI [?0.36, 1.13] for the per-protocol set, and 0.33, 90% CI [?0.25, 0.91] for the full analysis set, both within the pre-defined equivalence margin. The mean % change from baseline in total hip BMD at Month 12 was 3.5% and 3.2% in SB16 and DEN, respectively. The mean % change from baseline in femoral neck BMD at Month 12 was 2.8% and 2.3% in SB16 and DEN, respectively. The incidence and distribution of adverse events were comparable between SB16 and DEN up to Month 12. Serum CTX, P1NP and denosumab concentrations were comparable between SB16 and DEN up to Month 12. The median % change from baseline in serum CTX concentration over time was a decrease of at least 50% at all time points. Only 3 subjects (1 in SB16 and 2 in DEN) had non-neutralizing anti-drug antibodies.Conclusion: This study demonstrated biosimilarity of SB16 to DEN through equivalent efficacy and comparable PD, PK, immunogenicity and safety up to Month 12.

A Real-World Review of the Use of Romosozumab for Fracture Risk Reduction and Bone Optimization in an Orthopaedic-Based Fracture Liaison Service *Michael Gardner[1], Andrea Fox[1]. [1]Stanford University School of Medicine, United States

The novel bone-forming medication, romosozumab, was approved by the FDA in 2019 for use in postmenopausal females with a high risk of fracture. There is limited data on real-world experience with romosozumab in the US. This retrospective review describes the experience of 131 postmenopausal women at high risk of fracture who completed one year of romosozumab therapy between 2019-2022 in the setting of an orthopedic Fracture Liaison Service (FLS) clinic. Women were referred to the FLS for very recent fracture (n=84, 64.1%), bone optimization prior to elective surgery (n=35 patients, 25.7%), and high risk of fracture risk identified via DXA BMD or FRAX assessments (n=12 patients, 9.2%). Patients ranged in age from 51-93 with a mean age of 73 years. Forty-one patients (31.3%) were treatment naïve, while 90 (68.7%) had used a variety of antiresorptive (n=53, 55.7%) or anabolic (n=9, 0.1%) agents in the past. Reasons for selecting romosozumab as the treatment agent of choice included patient preference (32.8%), contraindications to PTH analogs (32.8%), current hypercalcemia or history of hyperparathyroidism (19.1%), aversion to daily injections (11.5%), cost as a hindrance to PTH analogs (10.7%), prior PTH intolerance (7.6%), and provider preference (4.6%). BMD increased at all measured sites over 12 months of therapy with romosozumab. Mean spine T-score improved from -1.99 to -1.14 with mean right hip increasing from -2.28 to -1.86. Few fractures on therapy were observed (n=9) during the treatment course. Of the 35 patients treated for bone optimization prior to surgical intervention, 18 patients (85.7%) met expected outcomes per surgical follow-up notes, 14 surgeries were still pending and 3 (14.3%) of patients had a documented interoperative or postoperative complication related to bone. Overall, treatment with romosozumab was well tolerated. The most commonly reported side effects were myalgias (9 patients, 6.9%) , injection site reactions (8 patients, 6.1%) , and headaches (3 patients, 2.3%) . Romosozumab was found to be an effective option for osteoporosis treatment in postmenopausal women at high fracture risk and those referred for surgical bone health optimization in an orthopedic-based FLS.

Effect of risedronate on bone loss after hematopoietic stems cell transplantation: A Prospective, Double-blinded, Randomized Controlled Trial *Jeonghoon Ha[1], Jinyoung Kim[1], Chaiho Jeong[1], Jeongmin Lee[1], Yeeje Lim[2], Ki-Hyun Baek[1]. [1]The Catholic University of Korea, Republic of Korea. [2]Seoul National University Bundang Hospital, Republic of Korea

Background Bone marrow transplantation (BMT) is an effective treatment for hematological diseases; however, it often leads to bone loss, the complex causes of which are not fully understood. Although bisphosphonates are recommended for these patients, there is limited evidence, particularly regarding risedronate. This study aims to evaluate risedronate as a potential solution for preventing bone loss in bone marrow transplant recipients. Methods We conducted a prospective, double-blinded, randomized controlled trial with 50 allogeneic BMT patients to assess the efficacy and safety of risedronate in preventing post-transplant bone loss. Participants were randomized into treatment (35 mg risedronate weekly) (n=26) or placebo groups (n=24), with both receiving calcium and vitamin D supplements. Intention-to-treat and per-protocol analyses were conducted. The primary endpoint was the change in bone mineral density (BMD) at the lumbar spine and femoral neck, measured at baseline, 24, and 48 weeks using dual-energy X-ray absorptiometry. Secondary endpoints included changes in serum calcium, phosphorus, 25-hydroxyvitamin D, osteocalcin, and carboxy-terminal cross-linked telopeptide of type I collagen (1CTP) levels. Results There were no statistically significant differences in age, gender, underlying hematologic conditions, bone turnover markers, and BMD between the two groups. At week 48, lumbar BMD decreased from baseline in both groups, with a 1.5% decrease in the risedronate group and a 6.5% decrease in the placebo group. For femoral neck BMD, there was an 8.7% decrease from baseline to week 48 in the risedronate group, compared to a 12.1% decrease in the placebo group. Total hip BMD decreased by 7.7% at 48 weeks in the risedronate group, in contrast to an 11.2% decrease in the placebo group. For 1CTP, levels rose rapidly in the placebo group 8 weeks after transplantation and then declined. In the risedronate group, levels rose slowly until week 24 and then declined. Overall, 1CTP levels were more suppressed in the risedronate group throughout the study. Conclusion Administering risedronate at a dose of 35 mg weekly for 48 weeks following allogeneic hematopoietic stem cell transplantation did not entirely prevent post-transplant bone loss. However, it reduce bone loss without serious side effects when compared to the placebo group.

Trends in osteoporosis drug initiation and use among community dwelling older adults *Kaleen Hayes[1], Sulbh Aggarwal[2], Suzanne Cadarette[2]. [1]Brown University, . [2]University of Toronto, Canada

Background: Many different therapy options exist for the treatment and prevention of osteoporosis. Introduction of new therapeutic options, updates to practice guidelines, media coverage of adverse drug events, and healthcare policy changes have likely affected the use of osteoporosis medications over time.Objective: To estimate the number of older adults with use of osteoporosis drugs and describe trends over time in Ontario, Canada, 1996-2022.Methods: The Ontario Drug Benefit (ODB) program covers prescription drugs listed on the formulary for all residents aged 65 years or older. We leveraged pharmacy claims (ODB) data to identify all community-dwelling older adults (aged 66 or more years) with dispensed prescriptions for oral bisphosphonates (alendronate, etidronate, risedronate), intravenous bisphosphonate (zoledronic acid), denosumab, teriparatide, nasal calcitonin, or raloxifene (females only) between May 27, 1996 (date of earliest claim) and December 31, 2022. The number of patients with initial use (no prior exposure history) and any use of each medication was plotted by calendar year, and patient age was summarized using descriptive statistics.Results: In total, we identified 712,036 unique community-dwelling older adults with use of an eligible osteoporosis medication during the study period (mean age=75.6 [standard deviation=7.2] years). Risedronate was the most common osteoporosis medication used, with 460,647 unique users, followed by alendronate (n=310,482), etidronate (n=303,620), denosumab (n=193,104), and raloxifene (n=22,205). Teriparatide (n=233) and calcitonin (n=1,669) were the least commonly used osteoporosis medications, likely due to ODB formulary restrictions for these medications and calcitonin's removal from the Canadian market in 2013. Large shifts were observed in the total number of users of any osteoporosis medication annually, from n=28,403 in 1997 to a peak of n=240,640 in 2009, then to n=200,912 in 2022. Shifts were especially large for denosumab (from n=12,580 in 2012 to a peak of n=114,778 in 2022) and etidronate (from a peak of n=126,478 in 2002 to virtually no users beyond 2017).Conclusion: We observed major fluctuations in the number of users of osteoporosis medications over time that likely reflect changes in policy, public perception, and clinical practice. Consideration must be given to the absolute number of users of each medication as well as time-trends when designing pharmacoepidemiologic studies of drug safety and effectiveness in this population.

SUN-438

Effect of combination therapy of eldecalcitol and risedronate on aromatase inhibitor induced bone loss in postmenopausal women with early-stage breast cancer: an open-label randomized trial *Yasuo Imanishi[1], Takumi Imai[2], Hisako Fujii[3], Rei Aida[2], Yuki Nagata[4], Tetsuo Shoji[4], Shinichiro Kashiwagi[5], Tsutomu Takashima[5], Masanori Emoto[1]. [1]Department of Metabolism, Endocrinology, and Molecular Medicine, Osaka Metropolitan University Graduate School of Medicine, Japan. [2]Department of Medical Statistics, Osaka Metropolitan University Graduate School of Medicine, Japan. [3]Department of Health and Medical Innovation, Osaka Metropolitan University Graduate School of Medicine, Japan. [4]Department of Vascular Medicine, Osaka Metropolitan University Graduate School of Medicine, Japan. [5]Department of Breast Surgical Oncology, Osaka Metropolitan University Graduate School of Medicine, Japan

As aromatase inhibitors (AIs) induces bone loss and increases fracture risk in women with hormone-positive, early-stage breast cancer (EBC), antiresorptive bone agents are

recommended to the patients with risk of fragility fractures. We aimed to compare the bone quantity and quality of the combination therapy of eldecalcitol and risedronate with risedronate alone in an open-label randomized control trial for 24 months. Postmenopausal women with hormone receptor-positive EBC (TNM stage 0-3A) treated with risedronate more than 12 months, and with T< -1.0 bone mineral density (BMD) at lumber spine (LS), femoral neck (FN), or total hip (TH), or fragility fractures on LS were randomly assigned to combination therapy or risedronate monotherapy. The primary outcome of this study is group difference in the change of LS BMD at 24 months, and BMD at FN and TH, and trabecular bone score (TBS) were also assessed for 24 months. A total of 200 patients were enrolled to the study between October 2012 to December 2019. Excluding the patients with no follow-up BMD data, 98 patients in each group were selected as a full analysis set. The increase in LS, FN and TH BMD at 24 months was larger in combination therapy group compared to monotherapy group, with a group difference (combination therapy minus monotherapy) estimate of 0.020 g/cm2 (95% confidence interval (CI) 0.010 to 0.029 g/cm2, p<0.001) for LS, 0.013 g/cm2 (95% CI 0.005 to 0.021 g/cm2, p=0.001) for FN, 0.017 g/cm2 (95% CI 0.008 to 0.025 g/cm2, p<0.001) for TH. However, no group difference was detected in the change in TBS at 24 months (estimate 0.008, 95% CI -0.006 to 0.021, p=0.266). Patients with osteopenic to osteoporotic status after risedronate treatment may be added on eldecalcitol in order to avoid bone loss induced by AIs.

SUN-439

Prognostic effect of Vitamin B12 and D levels on post hip fracture recovery *Angela G Juby[1], Christopher MJ Davis[2], Paula M Zubick[3], Mary Dunwald[3], Sebastian Lackey[4], Hoa Kong[4]. [1]University of Alberta, Faculty of Medicine and Dentistry, Canada. [2]University of Alberta, Faculty of Kinesiology, Canada. [3]University of Alberta Hospital Fracture Liaison Service, Canada. [4]Alberta Bone & Joint Health Institute, Canada

PurposeEpidemiological studies on the impact on bone of Vitamin B12 deficiency vary, but generally suggest that the lower the B12 level the higher the homocysteine level, and the higher the fracture risk. Yet other studies only showed an increased fracture risk with low plasma folate levels, but not plasma B12. Mouse studies also suggest low B12 may affect fracture healing. There are no reported studies evaluating the potential effects of B12 levels on post hip fracture recovery. This study was done to assess the prognostic effect of Vitamin B12 status on hip fracture outcomes. The hypothesis was that Vitamin B12 levels would be negatively associated with length of stay in post hip fracture patients.MethodsRetrospective analysis of hip fracture patients enrolled in a Fracture Liaison Service (FLS) in Alberta, Canada. Vitamin D and B12 levels measured on admission. Fracture outcomes were assessed by length of acute care stay (LOS-A), length of total hospitalisation (acute and rehabilitation) (LOS-T), and discharge location (compared to baseline). B12 and D levels were evaluated as both continuous and categorical variables (low <400pmol/L, sufficient >=400pmol/L; low < 80nmol/L, sufficient >=80nmol/L, respectively). Outcomes were corrected for patients' age and sex.ResultsData obtained from 456 patients seen between January 2017 and October 2019 (pre COVID-19). Age averaged 80.6 years (51-100), median 83yr, and included 354 females (77.6%). Low B12 was identified in 57.3% females, 57.8% males. Low D occurred in 55.9%. LOS assessments excluded those who died (10 patients, all in acute stage). Average LOS-A was 11.9 (2.2-119.3) days and LOS-T was 34.3 (2.6-445.9) days. LOS-A and LOS-T were significantly positively associated with age (p<.001) but not B12 or D categories. There was no interaction between age, gender, and B12 or D levels. LOS-A was weakly positively associated with absolute B12 levels (p=0.03) but not D levels (p=0.7). LOS-T showed no such association. LOS-T was correlated with LOS-A (p<.001).ConclusionsBoth absolute B12 and D levels, and categorical B12 and D status did not appear to be associated with acute or total hospital length of stay in this post hip fracture cohort. Longer length of stay was associated with increased age.

Antiresorptive Therapy to Reduce Fracture Risk and Effects on Dental Implant Outcomes in Patients with Osteoporosis: A Systematic Review and Consensus Statement *Aliya A. Khan[1], Dalal S. Ali[1], Reza Mirza[2], Archibald Morrison[3], Salvatore Ruggiero[4], Gordon Guyatt[2], Sotirios Tetradis[5]. [1]Division of Endocrinology and Metabolism, McMaster University, Canada. [2]Department of Health Research Methods, Evidence, and Impact at McMaster University, Canada. [3]Citadel Oral and Maxillofacial Surgery, Canada. [4]NYCOMS, United States. [5]University of California, Los Angeles, United States

Background: Placement of a dental implant in a patient on antiresorptive therapy has been hypothesized to increase the risk of Medication-Related Osteonecrosis of the Jaw (MRONJ) and/or impact implant survival. In patients with osteoporosis, the risk of MRONJ with antiresorptive therapy is only marginally higher than observed in the general population1. Due to the invasive nature of implant placement and the increased risk of MRONJ seen in patients undergoing an oral procedure or event2, the International ONJ Taskforce further evaluated this issue.Methods: A systematic review of the literature was conducted and evaluated the outcomes of implant placement in individuals with osteoporosis or osteopenia receiving antiresorptive therapy. The risk of implant failure was evaluated in comparison to age matched individuals not on antiresorptive therapy.Results: Seven studies reported comparative risk estimates of dental implant failure with and without antiresorptive therapy for osteoporosis or osteopenia. A random-effects meta-analysis revealed a non-significant increased risk with antiresorptive agents with wide confidence intervals (RR 1.56, 0.43 - 5.70). The data were reviewed by the International Taskforce, and consensus was achieved on the graded recommendation3,4.Conclusion: In patients with osteoporosis on antiresorptive therapy, the Taskforce suggests that antiresorptive therapy does not need to be stopped prior to proceeding with dental implant (weak recommendation, very low-quality evidence). Current evidence does not suggest an association between antiresorptive therapy and implant failure. There is no evidence that cessation of bisphosphonate or denosumab therapy improves implant survival or reduces the development of MRONJ. Cessation of denosumab is not advised as it has been associated with rebound bone loss and an increased risk of multiple vertebral fractures. This presentation will provide the recommendations of the International Taskforce and also provide details regarding possible pathogenesis and differences in healing following dental extraction in comparison to implant placementReferences: 1.Khan, et al., Diagnosis and Management of ONJ: A Systematic Review and International Consensus. SUN-441

Is it necessary to repeat BMD for patients receiving denosumab? Baseline results from a Quality Improvement initiative *Tayyab Khan[1], Mohammed AlAgha[2], Jenny Thain[2], Kristin Clemens[3]. [1]Department of Medicine, Western University, Canada. [2]Western University, Canada. [3]Division of Endocrinology and Metabolism, Western University, Canada

The utility of repeating Bone Mineral Densitometry (BMD) to monitor patients' response to anti-osteoporosis therapy has been questioned as a vanishingly small number of patients taking antiresorptive therapies (ie. bisphosphonates or denosumab) have convincing evidence of bone loss. This could be particularly the case for denosumab, which is the most potent among anti-resorptive therapies. In this quality improvement project, we aimed to reduce the proportion of patients who receive BMD testing every 2 years or less while on denosumab. As the first step in this process, we assessed the proportion of participants who had convincing evidence of bone loss defined as loss of BMD at the same site on repeat measurements, or loss of BMD at multiple sites on one measurement, and those who required a change in therapy. We then implemented our test of change (a policy to promote repeating BMD at >2year intervals in patients receiving denosumab) and measured outcome, process and balance measures. We included postmenopausal women being treated with denosumab at our institution who had at least two repeat BMD measurements following a baseline study. Prior to the implementation of our intervention, 20 consecutive patients with a mean age of 64.9 + 6.7 years had received denosumab for 7.1 + 3.4 years. Baseline BMD T scores were -2.6+1.2 at the lumbar spine (LS) and -2.4 + 0.5 at the femoral neck (FN). The average interval between baseline and first repeat, and between first and second repeat BMD was 23.0 + 11.7 months and 28.0 + 17.9 months, respectively. Only one of twenty patients (5%) experienced significant loss of LS BMD which stabilized on repeat measurement. No patient experienced a decrease in FN BMD from baseline to the first repeat BMD, while only one of 19 (5.2%) experienced loss in BMD at this site between first and second repeat measurement. No patient experienced loss of BMD at both sites between the baseline and final measurements. Four patients experienced fractures while on denosumab, but none of them were candidates for more potent therapies due to concerns regarding cost or contraindications. Our initiative suggests that among postmenopausal women treated with denosumab at the Osteoporosis and Bone Disease Program in London, Ontario, no patient demonstrated convincing loss of BMD at repeat measurements. We will investigate the utility and safety of reducing BMD testing in patients taking denosumab at our centre.

SUN-443

Cardiovascular Risk and Fracture Risk Among Women Initiating Treatment with Romosozumab or Denosumab *Ye Liu[1], Tarun Arora[2], Jingyi Zhang[1], S. Bobo Tanner[3], Jeffrey Curtis[1]. [1]University of Alabama at Birmingham, United States. [2]Foundation for Advancing Science, Technology Education and Research, United States. [3]Vanderbilt University Medical Center, United States

Background: Romosozumab (romo) and denosumab (dmab) are recommended for postmenopausal women with osteoporosis (OP) at high risk of fracture. The U.S. prescribing information includes a boxed warning that romo should not be initiated in patients with prior myocardial infarction or stroke in the prior year. For all other patients without recent MI or stroke, the warning recommends to consider whether the benefits of romo outweigh its risks. This study evaluated CV and fracture risks among patients who initiated romo referent to dmab users.Methods: We used Medicare data from 1/1/2017 to 9/30/2021 to identify women age >=55 newly initiating romo or dmab after 4/1/2019. Claims data was linked to electronic medical record (EMR) data from multiple PCORNet Clinical Research Networks. Comorbidities and medical history were identified from claims while biometric data and lipid test results were obtained from the EMR. The ACC/AHA pooled cohort risk equation was used

to calculate the 10-year CV risk. The FRAX algorithm was used to calculate 10-year risk of hip and major fracture (clinical spine, forearm, hip, or shoulder). We set the 75 percentile of each risk score as the cut-off for high CV and fracture risk. A scatter plot with 95% prediction ellipse was used to illustrate the relationship between CV risk versus the risk of fractures (Figure 1) at a patient level and to compare the cohort of romo vs. dmab patients. Multivariable logistic regression was used to evaluate the relationship between high CV or fracture risk and medication initiation.Results: A total of 197,515 new users of romo (n=14,596) or dmab (n=182,919) were eligible for analysis and 1072 were linked to PCORNet data. Figure 1 showed romo users had lower CV risk but comparable or higher risk for hip or major fracture compared with dmab users. Romo was more likely to be prescribed to patients with higher fracture risk but lower CV risk, compared with dmab. The odds ratios (95% CI) for initiating romo vs. dmab for high CV risk, hip fracture risk, and major fracture risk were 0.46 (0.26, 0.80), 0.97 (0.47, 2.01), and 1.83 (0.89, 3.75), respectively.Conclusion: In this cohort of older women with claims data linked to EHR data, patients with high CV risk were less likely to be given romo compared with dmab. These data suggest that the boxed warning regarding CV risk for romo appropriately influences clinical decision making of physicians when prescribing anabolic medications for osteoporosis patients.

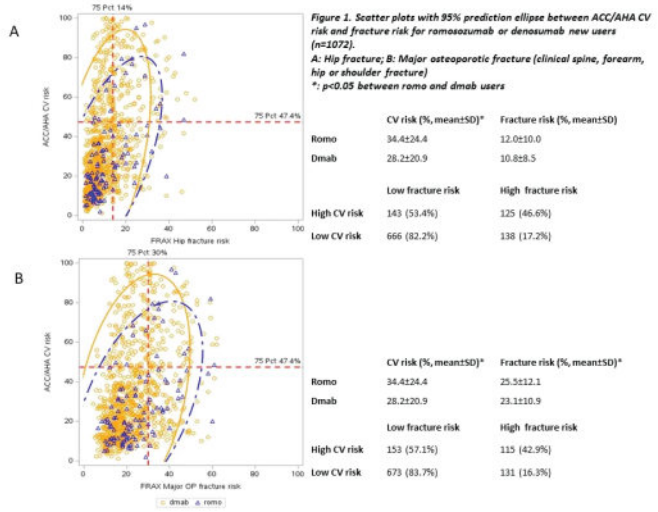

Figure 1. Scatter plots with 95% prediction ellipse between ACC/AHA CV risk and fracture risk for romosozumab or denosumab new users (n=1072).
A: Hip fracture; B: Major osteoporotic fracture (clinical spine, forearm, hip or shoulder fracture)
**: p<0.05 between romo and dmab users*

	CV risk (%, mean±SD)*	Fracture risk (%, mean±SD)
Romo	34.4±24.4	12.0±10.0
Dmab	28.2±20.9	10.8±8.5
	Low fracture risk	High fracture risk
High CV risk	143 (53.4%)	125 (46.6%)
Low CV risk	666 (82.2%)	138 (17.2%)

	CV risk (%, mean±SD)*	Fracture risk (%, mean±SD)*
Romo	34.4±24.4	25.5±12.1
Dmab	28.2±20.9	23.1±10.9
	Low fracture risk	High fracture risk
High CV risk	153 (57.1%)	115 (42.9%)
Low CV risk	673 (83.7%)	131 (16.3%)

Femur Geometrical Phenotypes in Atypical Femoral Fractures *Rashad Madi[2,] Julio Ojea Quintana[2,] Christiana Cottrel[2,] Rasleen Grewal[2,] Ani Ural[3,] Bruce J. Kneeland[2,] Gregory Chang[4,] Chamith S. Rajapakse[2,] [2]University of Pennsylvania, [,2]University of Pennsylvania, United States[,3]Villanova University, United States[,4]New York University, United States

Osteoporosis is a bone disorder characterized by the deterioration of bone microarchitecture, leading to fragility fractures in older individuals (1). Bisphosphonates are commonly employed as a first-line treatment for osteoporosis due to their ability to inhibit osteoclast function by binding to the bone's mineral matrix (2). Despite their effectiveness, long-term use has been associated with potential side effects, including atypical femoral fractures (AFF) (3). Our study investigates the demographic and radiological factors influencing AFF pathogenesis to improve prevention, diagnosis, and treatment strategies.Methods: We conducted a retrospective analysis of 65 patients who experienced AFFs after being treated with bisphosphonates for 3-15 years. The sample population consisted of 62 females and 3 males with an average age of 70.9 +/- 8.8 years. We utilized Sectra MSK (Version 24.2.6.5829, Linkoping, Sweden) to measure the following parameters on hip X-rays: 1) the distance from the lesser trochanter to the fracture, 2) medial and lateral cortical thicknesses, 3) femoral offset and 4) femoral neck angle (Figure 1).Results: The average distance from the lesser trochanter to the AFF was 59.1 mm (IQR: 32.3-96.9). The medial cortex width measured 7.3 mm (IQR: 6.5-8.4), while the lateral cortex width was 10.9 mm +/-2.5. Additionally, patients exhibited a femoral offset of 43.9 mm +/-7.1 and a femoral neck angle of 128.7° +/-4.8.Discussion: The etiology of AFFs is still not well understood. Several studies have identified potential geometrical features of the femur that may contribute to AFF formation in certain patients and at particular lateral subtrochanteric locations. Factors such as a decreased femoral shaft neck angle and increased femoral offset have been associated with heightened stress on the lateral subtrochanteric area, potentially explaining why fractures occur there (4). Recent advances in imaging analyses, such as CT and MRI finite element analyses, will facilitate further examination of the influence of geometrical, compositional, and biomechanical factors on AFFs. By integrating these findings with demographic and risk factor data, clinicians may be better equipped to predict which patients are at a high risk of developing AFFs before initiating bisphosphonate therapy. This information could help us consider alternative osteoporosis treatments or the implementation of more frequent bisphosphonate-free holidays for high-risk patients.

Effectiveness of zoledronic acid treatment within 14 days of hip fracture surgery. *Betiana Perez[1,] Ariela Kitaigrodsky[1,] Natalia Aliquo Maciel[1,] Ullman Tamara[1,] Lucia Coli[1,] Rodrigo Greco[1,] Ivan Huespe[1,] Mirena Buttazzoni[1,] Maria Diehl[1,] [1]Hospital Italiano de Buenos Aires, Argentina

Treatment with zoledronic acid (ZA) within 90 days after surgical repair of a hip fracture reduces the occurrence of clinical fractures and mortality. However, there is limited available data regarding the effectiveness of using ZA within the first two weeks. As lockdown limited follow-up during Covid-19 pandemic, ZA began to be indicated during hospitalization with calcium and vitamin D supplementation in our institution. AimTo evaluate the effectiveness of administering ZA within 14 days after surgical resolution of a hip fracture.MethodsRetrospective cohort study of patients >=65 years from a closed health system hospitalized in a tertiary care hospital for a fragility hip fracture between 04/2018 and 04/2022, comparing patients who received ZA within 14 days after surgery (Early-ZA) with those treated between days 15 and 90 after surgery (Later-ZA). The main outcome was the combined event of death or refracture. Analysis was made with chi2 or Fisher for qualitative variables and Wilcoxon for quantitative variables. We performed Kaplan-Meier survival analysis and Cox regressions. We adjusted the regression analysis considering age, Charlson Index and length of the initial hospital stay as potential confounders.ResultsOut of 848 patients, 220 received ZA within 90 days: 163 (74%) within 14 days following hip fracture surgery (Early-ZA) and 57 (26%) between days 15 and 90 (Later-ZA). Median age Early-ZA 88 (IQR 81-92) and Later-ZA 85 (IQR 80-88) p=0.054; 14% male without differences between groups (15.3% vs 10.5%, p=0.36). Median Charlson Comorbidity Index was significantly higher in patients receiving Early-ZA (median 5 IQR 4-5; vs Later-ZA 0 IQR 0-1; p<0.0001). Median hospitalization for hip fracture was 7 days (IQR 5-9) for both groups (p=0.76). During a median follow-up of 502 days, 38 patients died (17.3%); 27 had new fractures (12.3%). Regarding the combined outcome (death or refracture) we did not observe significant differences (Figure), with a crude HR of 1.314 (95%CI 0.74-2.35), and an adjusted HR of 1.011 (95%CI 0.46-2.22). ConclusionsZA administration during in-hospital stay enhances access to secondary fracture prevention. We did not observe differences in the combined outcome of refracture or

mortality between Early-ZA and Later-ZA after hip fracture in this preliminary study. After adjusting for confounding variables, HR changed substantially, suggesting a higher burden of comorbidities in patients treated in the first two weeks.

Baseline FRAX Score and Effectiveness of Romosozumab in Patients with Osteoporosis at a High Risk of Fracture in Japan: A Multicenter Retrospective Study *Akimitsu Miyauchi[1,] Etsuro Hamaya[2,] Junichiro Shimauchi[2,] Cae Tolman[3.] [1]Miyauchi Medical Center, Japan. [2]Amgen K.K., Japan. [3]Amgen Asia, China

Background: FRAX® has been incorporated into the initiation criteria for pharmacological treatment in the Japanese guidelines for prevention and treatment of osteoporosis (OP) (Orimo H, 2012). Efficacy of romosozumab on clinical, osteoporotic and major osteoporotic fractures was significantly greater in patients at high baseline FRAX probability compared with placebo in the FRAME study (McCloskey EV, 2021). Previously, we conducted a chart review of patients with OP at a high risk of fracture who received romosozumab for 12 months and then transitioned to another OP therapy for >=6 months to better understand the therapeutic profile of romosozumab in a real-world setting in Japan (Miyauchi A, 2021). In this analysis of the real-world study, we aim to explore the relationship between baseline fracture probability as measured by FRAX and the effectiveness of romosozumab based on absolute and percentage change in bone mineral density (BMD) from baseline. Methods: In this observational, multicenter, retrospective medical chart review, data were collected from 19 sites across Japan during the baseline period (12 months before romosozumab initiation [ie, index date]), the romosozumab treatment period (12 months), and a follow-up of >=18 months after the index date. Baseline FRAX scores were calculated with actual femoral neck BMD (g/cm2) or T-score. This analysis will include data collected from treatment-naïve patients during the baseline and the 12-month romosozumab treatment period.Results: Of the 462 treatment-naïve patients included in the chart review, baseline FRAX score was available for 217 patients (mean [SD]: 27.0 [10.68]) and baseline lumbar spine T-score was available for 346 patients (mean [SD]: -2.58 [1.31]). Final results will be reported on the day of presentation.Conclusion: Results of this study may provide insights into the clinical management of Japanese patients at higher baseline fracture risk receiving romosozumab treatment.

SUN-447

Parathyroid hormone levels following denosumab therapy vs. zoledronic acid therapy for osteoporosis *Pnina ROTMAN PIKIELNY[1.] [1]MEIR MEDICAL CENTER, ENDOCRINE INSTITUTE, Israel

Background:Denosumab (DMAb) and zoledronic acid (ZA) are potent, anti-resorptive agents used to treat patients with osteoporosis. It has been suggested that they increase parathyroid hormone (PTH) levels in response to their antiresorptive effect, and that PTH elevation might be responsible for DMAb modeling actions on bone. The timeline and magnitude of PTH elevation post-DMAb and ZA has not been characterized in a large patient population.Objective:To characterize PTH levels post-DMAb injection vs. baseline and vs. ZA infusion.Material and Methods:Female osteoporotic patients, >=50 years, treated with DMAb or ZA, 2008-2020 were included if PTH was 2mg/dl, vitamin D <50nmol/l or hyperparathyroidism. Post-injection PTH levels were linked time-wise to previous injections. Results: A total of 35,375 women, >=50 years received DMAb or ZA for the first time in 2008-2020; 26,341 met the exclusion criteria. Of the remaining women, 5,640 received a first DMAb injection and 3,394 ZA. The DMAb group was older (73.2 vs. 69.8 years), was treated more frequently with osteoporosis medications before the injection (56.5% vs. 50.3%) and more had sustained a fracture (15.8% vs. 13.9%) compared to the ZA group. Vitamin D level was 80.9+/-21.9 nmol/l. Repeat PTH was available for 2,206 DMAb patients and 1,444 ZA. Among 772 PTH measurements in the first month post-DMAb, it was >1.5ULN in 156 (20.1%) and >2.5ULN in 74 (5.1%), whereas among 807 PTH measurements 5-months post-injection, it was >1.5ULN in 112 (13.9%) and >2.5ULN in 9 (1.1%). One-month post-ZA, PTH was >1.5ULN in 35/169 (20.7%) and >2.5ULN in 11 (6.5%), and decreased to >1.5ULN in 23/213 (10.7%) and to >2.5ULN in 2/213 (0.9%), 5 months after injection.DiscussionThis is the first study to examine PTH levels in a large population receiving DMAb or ZA injections, with precisely-timed PTH measurements post-injection. PTH levels increased by >1.5ULN in 20% of osteoporotic patients who received DMAb or ZA, while it increased to >2.5ULN in ~5% post-injection. PTH levels declined gradually after treatment in both groups. It seems that PTH elevation is related to the antiresorptive effects of the drugs and is not a disease phenomenon. It is suggested to avoid checking PTH in the first few months post-DMAb and ZA therapy.

[10]Department of Hematology and Oncology, Ordensklinikum Linz - Barmherzige Schwestern, Linz, Austria, Austria. [11]Department of Internal Medicine III with Haematology, Medical Oncology, Haemostaseology, Infectiology and Rheumatology, Oncologic Center, Paracelsus Medical University Salzburg, Salzburg, Austria, Austria. [12]Medical University of Vienna, Comprehensive Cancer Center, Vienna, Austria; ABCSG, Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria, Austria

Background: The placebo controlled randomized phase III ABCSG-18 trial demonstrated that denosumab significantly reduced clinical fractures in postmenopausal patients with breast cancer. Concern exists about a potential rebound effect after treatment discontinuation with denosumab. In line with this, an earlier analysis of ABCSG-18 showed an increased risk for vertebral and multiple vertebral fractures after stopping denosumab. We have therefore conducted a randomized sub-study investigating the use of a single dose of zoledronic acid (ZA) at the end of denosumab therapy. Here we present the first data on bone turnover markers (BTM).Patients And Methods: Patients of the ABCSG-18 trial who had completed denosumab treatment were randomized to a single dose of ZA 5mg i.v. versus nil(=SOC). ZA was administered 8 months+/-4 weeks after the last dose of denosumab (day 1 of this sub-study). DXA scans, lateral spine X-rays and BTM (CTX and osteocalcin) were assessed at baseline and at 6, 12 and 18 months thereafter. New fractures were assessed throughout. The percent change from baseline was derived and compared between arms with stratified Wilcoxon rank sum tests.Results: 50 patients with a median age of 71 years were randomized into this prospective sub-study. 24 received ZA, and 26 did not. Patient groups were well balanced with respect to baseline bone health factors. All patients of the ZA arm and 25 of the SOC arm received 7 doses of denosumab in the ABCSG-18 trial. At baseline, mean CTX was 0.57 ng/ml in both arms, mean osteocalcin was 19.5 ng/ml in the ZA arm and 18.8.ng/ml in the SoC arm. Percentage change of CTX differed significantly between the two arms with a median decrease of CTX after 6 months (-50.0%) and 12 months (-49.5%) in the ZA arm, and a median decrease after 6 months (-7.0%) and after 12 months (-6.5%) in the SOC arm. Accordingly, osteocalcin decreased by a median 17.0% after 6 months and 13.9% after 12months in the ZA arm, but increased by 110.8% after 6 months and by 29.4% after 12 months in the SOC arm. No significant difference of the BTM could be seen after 18 months. Importantly, the observed increase of BTM in the SOC arm was driven by a few patients with major changes - up to 778.6% for CTX and up to 679.6% for osteocalcin.Conclusion: These first data of the randomized sub-study of the ABCSG-18 trial demonstrate that a single

dose of ZA prevents a high bone turnover state that occurs in some patients of the SOC arm after stopping denosumab.

Introduction of a Standardized Hip Fracture Order Set Improves Osteoporosis Medication Initiation and Persistence: A Population-Based Before-After Analysis *Gabriel Larose[1], Saeed Al-Azazi[1], Lisa Lix[1], Eric Bohm[1], William Leslie[1]. [1]University of Manitoba, Canada

Background: Osteoporosis-related fractures pose a great burden for society, with a high risk of subsequent fractures after a first fragility fracture. Introducing standardized care can improve the rate of initiation of osteoporosis treatment. This project evaluated osteoporosis medication initiation, persistence and fracture prevention after hip fracture.Methods: Within the Canadian health system, our region introduced a hip fracture order set (OS) that included recommendations for the initiation of osteoporosis medication for secondary prevention beginning in one of the hospitals in 2015 (Group 1). A control group (Group 2) had delayed introduction of the same OS in other hospitals (after 2017). A retrospective cohort study was conducted using linked administrative health data. All women and men 50+ years with surgical treatment for a low-energy hip fracture between 2010 and 2019 were included. Individuals were followed until 2021 for evaluation of osteoporosis medication initiation, medication persistence at 1 year and secondary fractures. Group comparisons used chi-square tests. Logistic regression models tested the impact of patient factors on initiation and persistence of osteoporosis medication.Results: Group 1 (early OS) included 813 patients and Group 2 (delayed OS) included 2150 patients. No significant differences in demographics, socioeconomic status or comorbidities were observed. A significant increase in osteoporosis medication initiation by 30 days post-fracture was seen with OS introduction (Figure 1). Group 1 treatment initiation was 9.7% in the year before and 47.8% in the year after OS introduction (P<0.001). This increase was sustained in later years and contrasted with Group 2 where no comparable change was seen. Similar improvements were seen in medication initiation by 90 days, 180 days and 365 days post-fracture. Persistence on osteoporosis medication at 1 year was also increased (Group 1 year before OS: 16.8%; year after OS: 35.0%, p<0.001). Logistic regression showed a significant impact of sex, diagnosis of osteoporosis, and OS utilization on medication initiation and persistence at 1 year. No difference in secondary fragility fractures was observed (Group 1: 19.8%; Group 2: 18.8% p=0.38).Conclusion: Introduction of the hip fracture OS significantly increased osteoporosis medication initiation and persistence at one-year post-fracture. However, there were no significant differences in secondary fractures.

SUN-450

Evaluation and treatment of Osteoporosis after hospitalization with hip fractures: how effective are we *Catherine Anastasopoulou[1], Sri Ram Teja Sathi[2], Corina Nava Suarez[2], Sana Ahsun[2], Abhiram Javvaji[2], Michael Ngu[3]. [1]Sidney Kimmel Medical College at Jefferson University, United States. [2]Einstein Endocrinology, United States. [3]Einstein Medical Center, United States

Background: Hip fractures substantially increase the risk of major morbidity and death in older patients. Osteoporosis is a major risk factor for hip fracture. Patients with hip fractures have an increased risk for recurrent fractures following the first one [1] and low bone mineral density appears to be an additional and independent indicator for future fracture risk [2]. It is, therefore, important to assess bone mineral density to evaluate and properly treat osteoporosis after a hip fracture to decrease the risk for recurrent fractures [3,4].Purpose: The purpose of our study was to identify how effective we are in evaluating and treating osteoporosis in patients who have sustained a hip fracture.Methods: A total of 260 patients with a fragility hip fracture (low-trauma) occurring between 2015 and 2019 were identified from medical records at a large tertiary care hospital in USA. Data was collected about demographics, recurrent fractures, DXA scans, 25 hydroxy vitamin D levels, and type of treatment offered.Results: Out of 260 patients, 172 (66.1%) were female and 88 (33.9%) were male with a median age 79 [35-105]. Demographics showed 121 of total 260 (50.3%) were African American, 95 (36.5%) Caucasian, 14 (5.3%) Asian, and 21 (8.0%) other. 19 of the total 260 (7.3%) had a DXA scan done, and 20 (7.6%) received osteoporosis treatment after hip fracture. Of the 20 patients treated, 16 received bisphosphonate (one patient got IV medication and 15 oral therapy), 2 denosumab, 1 estrogen, and 1 teriparatide. 20 patients (7.6%) had a subsequent fracture. 25 hydroxy vitamin D level was checked in 101 (38.8%), vitamin D was supplemented in 91 (35%) and calcium supplements were initiated in 40 (15.3%) patients.Conclusion: In the post-operative follow up for fragility hip fracture, osteoporosis is still underrecognized and undertreated. In our study, fragility hip fractures, which already indicate significant osteoporosis complication, did not prompt physicians into further action. This calls for initiatives to increase awareness for better recognition and treatment of osteoporosis and further studies could help identify barriers to promote interventions.

SUN-451

The efficacy of sequential therapy with romosozumab followed by denosumab compared to denosumab alone in hemodialysis patients *Yuichiro Tamagawa[1], Hitoshi Tanigawa[2]. [1]Japan Community Health care Organization Shiga hospital, Japan. [2]Center for Regenerative Medicine and Skeletal Development, Uconn Health, United States

Hemodialysis patients have a high rate of osteoporosis and are a high-risk group for fractures. However, some osteoporosis drugs are contraindicated to severe renal failure patients, and treatment strategies for patients with severe osteoporosis aren't well established. Romosozumab is a monoclonal anti-sclerostin antibody that has the dual effect of increasing bone formation and suppressing bone resorption, reducing the risk of fracture within 12 months. This study aimed to compare the effects of one year of romosozumab followed by one year of denosumab (group R) to two years of denosumab (group D) on bone mineral density (BMD) and bone metabolism markers in hemodialysis patients with severe osteoporosis. This study was a single-center, retrospective study. 19 patients were in group R and 23 in group D, they are all hemodialysis patients. All patients were given these treatments as their first treatment for osteoporosis. Both groups showed significant increase in BMD(T-score) at the lumbar spine and femoral neck after 6 months treatment (group D: +0.32; group R: +0.70), with group R showing a significant increase compared to group D in BMD at the lumbar spine (p=0.0024). The bone metabolism marker P1NP increased significantly in group R at 6 months (+57.4%, p=0.002 vs baseline), and decreased significantly at 12 months (-17.4%, p=0.001 vs baseline). Adverse events were few and none were fatal, including cardiovascular events. P1NP level of group D showed a consistent decrease from baseline. The bone resorption marker TRACP-5b also showed a significant decrease compared to baseline after 6 months in both groups (group D: -42.9%; group R: -17.4%), with group D showing a consistently greater decrease in all the periods. No obvious fractures were not observed. These results suggest that romosozumab treatment followed by denosumab may be a potentially good strategy for hemodialysis patients with severe osteoporosis.

SUN-452

Cost-Effectiveness of Four Treatment Approaches for Osteoporotic US Women and Men With a Recent Hip Fracture *Mickael Hiligsmann[1], Yamei Wang[2], LENY PEARMAN[4], John Caminis[4], Stuart Silverman[5], Andrea Singer[6], Jean-Yves Reginster[7]. [1]Maastricht University, Netherlands. [2]Radius Health, Inc., United States. [4]Radius Health, . [4]Radius Health, United States. [5]Cedars-Sinai/UCLA, United States. [6]MedStar Georgetown University Hospital, United States. [7]University of Liège, Belgium

Hip fracture is the most severe osteoporotic-related event, with dramatic consequences to the patients' quality and quantity of life. Furthermore, hip fractures substantially increase the risk of a subsequent fracture, especially in the near term. Common treatment approaches for these patients at very high fracture risk include sequential treatment with an anabolic agent (either abaloparatide [ABL] or unbranded teriparatide [TPTD]) followed by an antiresorptive agent (eg, alendronate [ALN]), or monotherapy with ALN. Many patients at very high fracture risk do not receive osteoporosis medication; unfortunately, "no treatment" must therefore be included as a comparator. Few economic evaluations have assessed the cost-effectiveness of these four treatment approaches, and in particular in patients with a recent hip fracture. Using a microsimulation-based Markov model previously validated, lifetime healthcare costs (in 2022 dollars) and quality-adjusted life years (QALYs) were estimated for the four treatment approaches: sequential ABL/ALN, sequential unbranded TPTD/ALN, ALN monotherapy, and no treatment. Analyses were conducted in US women and men aged 50-90 years who had a recent hip fracture and bone mineral density T-score <=?2.5. In both sexes and over the full age range, no treatment was dominated (ie, it incurred higher costs for lower QALYs) by ALN monotherapy, and sequential unbranded TPTD/ALN was dominated by sequential ABL/ALN. Between the two remaining approaches, sequential ABL/ALN was cost-effective compared to ALN monotherapy in men aged >=50 years and in women aged >=55 years at the US threshold for cost-effectiveness, estimated at $150,000

per QALY gained. Results were robust over various sensitivity analyses. By example, probabilistic sensitivity analyses revealed that sequential ABL/ALN was cost-effective in at least 90% of the simulations in both US men and women aged 70 years. In conclusion, this study suggests that sequential ABL/ALN is the most cost-effective intervention among the four treatment approaches in both US men (aged >=50 years) and women (aged >=55 years) with osteoporosis and a recent hip fracture. Treating patients with recent hip fractures by sequential ABL/ALN could lead to cost-effective use of healthcare resources.

Pharmacokinetic Equivalence of CT-P41 to Reference Prolia: A Randomized Phase I Study in Healthy Male Subjects *Anhye Kim[1], Janghee Hong[2], Wonsuk Shin[1], Hyounggyoon Yoo[1], Jin-Gyu Jung[2], Jean-Yves Reginster[3], Sunghyun Kim[4], Yunju Bae[4], Jeehye Suh[4], Sera Kim[4], Eunkyung Lee[4], Stuart Silverman[5]. [1]Department of Clinical Pharmacology and Therapeutics, CHA Bundang Medical Center, CHA University School of Medicine, Republic of Korea. [2]Chungnam National University, Republic of Korea. [3]Division of Public Health, Epidemiology and Health Economics, University of Liège, Belgium. [4]Celltrion, Inc., Republic of Korea. [5]Cedars-Sinai/UCLA, United States

Purpose: CT-P41 is a human monoclonal antibody developed as a biosimilar to the reference product, Prolia. This study aimed to demonstrate pharmacokinetic (PK) equivalence of the proposed biosimilar, CT-P41 to US-licensed Prolia in healthy male subjects.Methods: In this double-blind, parallel-group, phase I trial, healthy male subjects were randomized (1:1) to receive a single 60 mg subcutaneous injection of CT-P41 or US-licensed Prolia and followed up until Day 253. The primary endpoints for PK equivalence were area under the concentration-time curve from time zero to infinity (AUC0-inf), AUC from time zero to the last quantifiable concentration (AUC0-last) and maximum serum concentration (Cmax). PK equivalence was concluded if 90% CIs for geometric least-square means (GLSMs) ratios were within the equivalence margin of 80-125%, using ANCOVA. Additional PK, pharmacodynamics (PD) measured with bone turnover marker (serum type 1 C-telopeptides [s-CTX]), safety, and immunogenicity were evaluated as secondary objectives.Results: Of the 154 randomized subjects aged from 28 to 55, 151 subjects (CT-P41:74; US-licensed Prolia: 77) received the study drug. The 90% CIs of GLSMs ratios for all primary endpoints were within the prespecified equivalence margin (AUC0-inf: 100.39-114.65; AUC0-last: 99.92-114.28; Cmax: 95.20-107.34). Secondary PK parameters and mean serum concentrations were comparable between the treatment groups. As serum concentrations of CT-P41 and US-licensed Prolia increased, serum level of s-CTX was decreased by 87% from baseline (Figure 1). Median % change from baseline of s-CTX was comparable between the treatment groups and trended toward back to baseline.Overall, 55 (74.3%) and 59 (76.6%) subjects reported >=1 treatment-emergent adverse event (TEAE) in the CT-P41 and US-licensed Prolia treatment groups, respectively. The most frequently reported TEAE was blood calcium decreased (CT-P41: 37.8%; US-licensed Prolia: 45.5%), and all were Grade 1 or 2 in intensity. No treatment-emergent serious adverse event was reported. The immunogenicity profiles were comparable between the treatment groups.Conclusions: In conclusion, PK equivalence for single-dose administration of CT-P41 and US-licensed Prolia was demonstrated in healthy male subjects. Mean serum concentrations, secondary PK parameters, PD, and safety profiles, including immunogenicity, were comparable between the treatment groups and no new safety signals with CT-P41 were identified.

Allograft vs Cement Void Filler and Postoperative Metabolic Drug Therapy: Impact on Pain, Function, and Height Restoration in the 1-Year Period After Kyphoplasty for Vertebral Compression Fractures *Moshe Schneiderman[1], Jeri Nieves[2], Edward Yoon[3], Joseph Lane[3]. [1]Hospital for Special Surgery; SUNY Downstate College of Medicine, United States. [2]Columbia University and Hospital for Special Surgery, . [3]Hospital for Special Surgery, United States

PURPOSE: Osteoporotic VFs are a serious public-health issue. Both the actual treatment of the fracture and the metabolic drug therapy may influence patient outcomes. Although cement kyphoplasty is a valuable tool in the treatment of VFs, the use of cement comes with risks, including potential embolization to the lungs or heart. To lessen these risks, we switched to performing kyphoplasty using structural allograft beads of bone, which are too large to enter the venous system. We tested the allograph vs cement for functional efficacy and analyzed the impact of metabolic drug therapy on pain, function, and height restoration in the year following kyphoplasty.METHOD: We performed a retrospective study of patients who underwent kyphoplasty between January 2018 and April 2023 for osteoporotic VFs and were treated by the same surgeon at the same institution in a large urban area. Patients with at least one MRI/CT or PROMIS-29 completed within the 1-year postoperative period were included. A total of 100 patients met these criteria. Vertebral height restoration was measured by comparing pre- and post-operative MRI/CT. Postoperative PROMIS-29 NRS Pain and Physical Function scores were recorded. A linear mixed-effects model for repeated measures was used to analyze the data. Independent variables included allograft vs cement and duration of postoperative osteoporosis drug therapy. Gender, smoking status, weekly alcohol consumption, and time since surgery were included as covariates.RESULTS: Allograft was associated with less postoperative pain (p=.03) and greater physical function (p=.009) than cement kyphoplasty during the 1-yr postoperative period. For anterior height, there was a dose-response relationship between postoperative time on teriparatide (p=.02), or on denosumab (p=.03), and increased height retention over the 1-yr period. For medial height, allograft was associated with significantly greater height retention than cement (p<.001) over the 1-yr period. Abaloparatide also showed a dose-dependent effect on height retention: Longer time on the drug was associated with greater medial (p=.03) and posterior (p=.001) height retention.CONCLUSIONS: Allograft kyphoplasty is associated with significantly less pain, greater physical function, and greater medial height restoration. There was no difference in anterior or posterior height restoration between allograft and cement. Metabolic drug therapy after kyphoplasty improves retention of vertebral height.

Effect of geographic region on zoledronic acid-related fracture risk reduction in postmenopausal osteoporosis *Austin Thompson[1], Elaine Yu[2], Annette Adams[3], Mary Bouxsein[4], Richard Eastell[5], Dennis Black[6]. [1]University of California, San Francisco, , [2]Massachusetts General Hospital, United States, [3]Kaiser Permanente Southern California, United States, [4]Beth Israel Deaconess Medical Center, Harvard Medical School, United States, [5]University of Sheffield, United Kingdom, [6]UC San Francisco,

Geographic differences in osteoporosis prevalence exist. Bisphosphonates (BP) are commonly used to treat osteoporosis, yet some evidence suggests the bioavailability or effectiveness of BPs may vary by geographic regions. Additionally, important differences in BP treatment and incidence of hip and atypical femoral fractures by race have been documented. We sought to evaluate whether the fracture reduction effects of zoledronic acid (ZOL) is greater in Asian regions compared to non-Asian regions.This secondary analysis of the Health Outcomes and Reduced Incidence with Zoledronic Acid Once Yearly (HORIZON) Pivotal Fracture Trial included postmenopausal women with osteoporosis and/or vertebral fractures who were randomly allocated to receive ZOL or placebo. Radiographs were used to assess morphometric vertebral fractures at baseline and at 12, 24, and 36 months, and clinical fractures were ascertained and adjudicated at each interview and clinic visit. Each participating clinical site was categorized as an Asian or non-Asian regional site. Estimated associations between ZOL treatment and fracture outcomes (morphometric vertebral, hip, non-vertebral, any clinical, and clinical vertebral fractures) were quantified as risk ratios (RR) or hazard ratios (HR) with 95% confidence intervals (CI) using a log-binomial regression and proportional hazard models, respectively. Effect modification by geographic region was evaluated using an interaction term for treatment and geographic region in each model. Among 7,765 post-menopausal women (1,090 from Asian regions), baseline characteristics were similar between treatment and placebo groups; although, women from Asian regions were more likely to be younger, have lower BMI, have lower BMD, and have baseline vertebral fracture. Those treated with ZOL were less likely to have morphometric vertebral fractures compared to women on placebo (RR 0.32, CI 0.26-0.39). This association differed by geographic region (RR 0.20, CI 0.11-0.34 in Asian regions; RR 0.35, CI 0.29-0.44 in non-Asian regions, p = 0.048) (Figure). In general, the other fracture outcomes followed a similar trend, although not statistically significant.These results suggest morphometric vertebral fracture risk reduction with ZOL treatment may vary by geographic region (Asian vs. non-Asian), though substantial risk reductions existed in each region. Future research should substantiate these findings with bone markers.

Comparative Microarchitecture Changes of Alendronate or Raloxifene after Denosumab (CARD HR-pQCT) *Joy Tsai[1], Mackenzie Jordan[2], Savannah Ryan[2], Benjamin Leder[3]. [1]MASSACHUSETTS GENERAL HOSPITAL, United States, [2]Massachusetts General Hospital, United States, [3]Massachusetts General Hospital Harvard Medical School, United States

Background: When denosumab is discontinued, antiresorptive therapy is necessary to mitigate high bone turnover bone density losses. In the CARD study, we demonstrated that after 12-month of denosumab, 12-months of alendronate was better able to maintain bone mineral density gains versus 12-months of raloxifene (manuscript in press). In this exploratory analysis, we wished to evaluate the comparative changes in peripheral compartmental volumetric bone mineral density and microarchitecture among those receiving alendronate and raloxifene.Methods: Postmenopausal women (60-81yo) at high fracture risk received denosumab 60-mg SC every 6 months for 12-months followed by 12-months of alendronate 70 mg weekly (N=26) or raloxifene 60 mg daily (N=22). Total, trabecular, and cortical density (Tot.vBMD, Tb.vBMD, Ct.vBMD) and cortical porosity (Ct.Po) were measured by high-resolution peripheral quantitative CT (HR-pQCT) of the distal tibia and radius.Results: As shown in the figure below, after 12-months of denosumab treatment, Tot. vBMD and Ct.vBMD at the tibia increased significantly. These increases were maintained during months 12-24 in both those randomized to alendronate or to raloxifene, with no significant between-group differences. Tb.vBMD at the tibia did not significantly change after 12-months of denosumab but then trended toward an increase between months 12-24 in both the alendronate and raloxifene groups with no significant between group differences. At the radius, similar changes in Tot.vBMD, Ct.vBMD, Tb.vBMD were observed. Ct.Po remained stable over the entire study period at the radius and tibia in both treatment groups.Conclusions: 12-months of denosumab modestly improved compartmental bone density without significantly changing cortical porosity at both the distal tibia and distal radius. These vBMD changes were maintained by both 12-months of alendronate or raloxifene. In conjunction with the previously presented aBMD by DXA results, these results support the consideration of raloxifene after short term denosumab as alternate therapy for those who cannot or do not wish to take bisphosphonates.

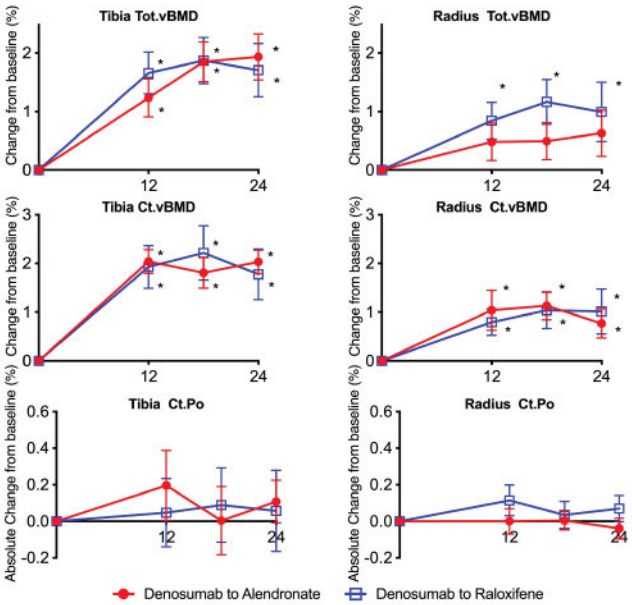

Figure. Mean % change (SEM) in bone density. *P<0.05 within group change from month 0.

The long-term effect of omeprazole on BMD in patients treated with calcicum, vitamin D and antiresorptive drugs *Vaclav Vyskocil[1], Radka Stepanova[2], Marie Simeckova[2]. [1]Charles University Hospital, Czech Republic. [2]ANOVA, Czech Republic

The authors analyzed a group of 399 patients treated with omeprazole for more than 2 years to determine the negative impact on BMD in patients treated with calcium, vitamin D, and antiresorptive drugs. The control group consisted of 340 patients selected to match the demographics of the study group. The primary endpoints were changes in BMD in the spine and hip, incidence of fractures, and their number in selected locations - hip, spine, upper limbs, lower limbs except for the hip, and other locations.The effect of the dose and duration of omeprazole treatment and of BMI on changes in spine and hip (active group) was tested. Additionally, the effect of vitamin D level was examined, the threshold was set to 50 nmol/L and 75 nmol/L. Majority of the treated patients had BMI higher than 25 (81.1%), respectively higher than 30 (44.5%), vitamin D values higher than 50 nmol/L was in 81.7% of patients. The mean age was 72.5 (+/-4.32) years. The most frequently used dose of omeprazole was 40 mg in 44.1% and 20 mg in 40.6% patients. The average duration of treatment was 6.4 (+/-3.23) years. The t-test for indepentend groups, linear models and Poisson regression were used for statistical testing.Results:No statistically significant difference was found in the spine and left hip BMD between groups. The effect of omeprazole dose and duration of treatment examined by a linear model was not statistically significant on both variables. The effect of BMI on BMD % change in the spine or hip was not statistically significant, both in the group with a threshold of 25kg/m2 and 30kg/m2. No statistically significant effect of vitamin D treatment was found on BMD changes in the hip or spine in both subgroups (thresholds of 50 nmol/l and 75 nmol/l). Similarly, the dose or duration of omeprazole treatment did not affect the number of fractures . Regarding the interaction of dose and duration of omeprazole treatment and the occurrence of fractures for the above-mentioned 5 locations, statistical significance was not found.The effect of dose or duration of omeprazole treatment on BMD or fracture occurrence was not proven considering vitamin D levels and BMI. Additional analysis of extended sample as well as update of clinical data needs to be performed.

Clinical and Radiological Characteristics of Southeast Asian Women with Atypical Femoral Fracture Compared with Age Matched Controls with Similar Bisphosphonate Exposure *Kuan Swen Choo[1], Le Roy Chong[1], Jemima Koh[1], Li Hnn Goh[1], Thomas FJ King[1], Linsey Utami Gani[1]. [1]Changi General Hospital, Singapore, Singapore

Bisphosphonate (BP) remains the 1st line of osteoporosis treatment in most patients due to its effectiveness in reducing osteoporotic fractures. Asians have upto 6 times higher risk of developing atypical femoral fracture(AFF) compared to Caucasians, with those from Southeast Asia displaying the highest incidence. In this study, we aim to characterize the clinical risk factors and femoral geometries in Singaporean women with AFF compared with age matched controls with similar BP exposure. We hope to elucidate predisposing risk factors for AFF in patients on BP.Methods: A case control study was conducted on female subjects admitted to Changi General Hospital, Singapore, with AFF from 2009 to 2022. 35 subjects were matched to 35 controls in terms of age. AFF was ascertained by the ASBMR 2014 criteria. Demographic data, clinical and medication history, and bone mineral density were extracted from the hospital electronic database. Femoral geometry parameters obtained from full-length lower limb radiographs were analysed for lateral bowing angle, femorotibial angle, femoral neck-head offset ratio, femoral neck-shaft angle, hip axis length, femoral offset, lever-arm ratio, line bisecting long axis of femur and pelvic center, and femoral shaft lateral cortical thickness index. 2 groups comparison were tested based on the nature and distribution of the outcomes.Results: The 2 groups of AFF and controls were well matched in their demographics and clinical characteristics (Table1). 26 out of the 70 subjects had previous osteoporotic fracture. Mean duration of BP use was similar in both groups [77.3 versus 73.4months for AFF and controls (p-value 0.608)]. Pre-BP treatment BMD in the AFF group were significantly higher at femoral neck. BMD at the time of AFF were also higher compared to controls at the time of recruitment. There were no significant differences in the femoral geometry parameters, except femoral head-neck offset ratio was statistically smaller in AFF group [0.671 versus 0.695, p-value 0.018], but the small ratio difference was unlikely of clinical significance.Conclusion: In a well-matched group of women with similar BP exposure, there were no significant differences in clinical characteristic and femoral geometry that suggest higher risk for AFF formation. We observed higher BMD at pre-BP treatment and time of fracture for patients with AFF. Further studies are needed to elucidate predisposing factors for AFF development in this high-risk group.

Table 1: Comparison of demographics, clinical variables, bone mineral density (BMD) and femoral geometries between the AFF and control groups.

Impact of Multidisciplinary Fracture Liaison Service in Post-fracture Care in Acute Hospital *Yasumasa Yoshino[1], Yohei Asada[1], Hidemi Muramatsu[2], Takahiro Toda[3], Takao Tobe[3], Shiho Asai[4], Masahiro Hidaka[5], Mitsuhiro Morita[6], Nobuyuki Fujita[6], Atsushi Suzuki[1]. [1]Department of Endocrinology, Diabetes and Metabolism, Fujita Health University, Japan. [2]Nursing Department, Fujita Health University Hospital, Japan. [3]Department of Pharmacy, Fujita Health University Hospital, Japan. [4]Food and Nutrition Service Department, Fujita Health University Hospital, Japan. [5]Department of Rehabilitation, Fujita Health University Hospital, Japan. [6]Department of Orthopedic Surgery, Fujita Health University, Japan

?Purpose? Fracture Liaison Service (FLS) is nowadays well accepted as effective coordinator-based system to prevent secondary fracture. Japan Osteoporosis Society offered multidisciplinary approach with a framework named as Osteoporosis Liaison Service (OLS)-7 (Suzuki A: Endocr J in press) in order to provide coordinated care for patients with osteoporosis. In this study, we aimed to explore the efficacy of multidisciplinary team care for post-fracture patients in acute care hospital.?Methods?The patients with primary osteoporosis (n=75, M/F=19/56, age 79.8 +/- 8.6 years old), who admitted to our hospital due to hip fracture or new clinical vertebral fracture, were recruited from 2018 to 2020. At enrollment, risk assessment as well as guidance of nutrition, medication and exercise were provided according to the OLS-7. On discharge, anti-osteoporotic medications were initiated. The questionnaires to each patient were conducted at 6, 12, 24, and 36 months after fracture.?Results? The study subjects included 65 hip fractures and 10 clinical vertebral fractures. OLS-7 includes 7 elements: (1) Fracture risk assessment, (2) Prevalent fracture and other causes of secondary osteoporosis, (3) Nutrition, (4) Fall risk and exercise, (5) Medication review and guidance, (6) QOL and ADL, (7) Database. Multidisciplinary team was in charge of assessment and guidance on post-fracture patients with OLS-7 framework. Medications for secondary fracture prevention was initiated in all patients. The breakdown was 41 bisphosphonates, 27 denosumab, 3 teriparatide, 1 romosozumab and 3 alfacalcidol alone. A total of 35 patients discontinued the medication at 36 months (11 died, 2 poor general condition, 10 refused to continue, 10 were unreachable, and 2 developed other skeletal dysplasia). Of the 40 patients confirmed alive at 36 months, 38 continued the medication, and 2 discontinued. Secondary fractures were observed in 12 cases in 10 patients.?Conclusion?Medication adherence was 95.0 % in surviving patients with a continuous approach, though it stayed at 50.7 % of the patients at enrollment.

SUN-461

Co-morbidity in Patients with Fragility Fracture and Impact on Osteoporosis Treatment Choices *Amina Anwar[1], Lucas Steele[1], Aamir Kadri[2], Madhumathi Rao[2]. [1]University of Kentucky College of Medicine, United States. [2]University of Kentucky,

Introduction Among patients who sustain a fragility fracture, <20% receive treatment for osteoporosis. The 2020 AACE guidelines characterized these patients as very high risk for re-fracture and recommended osteo-anabolics as first line for secondary fracture prevention. However, patients with fragility fractures have a high burden of co-morbidities that can significantly impact choice of osteoporosis therapy. We undertook a study of patients who sustained a fragility fracture to characterize their co-morbidity and evaluate the impact on subsequent therapy choices in the context of AACE guidelines and FDA label indications. Methods Retrospective chart review of patients with fragility fracture treated at a single institution from 2021-2022, and obtained data regarding demographics, co-morbidities, osteoporosis risk factors, lab values, clinical outcomes, and post-fracture treatment. We characterized the distribution of comorbidity and estimated the proportion of patients who post-fracture care. In addition, we approximated the proportion of patients where co-morbid conditions could preclude the use of osteo-anabolic agents. Proportions compared using Chi-square analysis and means using the independent sample t-test with significance at p=0.05. Results 197 patients with mean age 78 years (SD=9.6 years), gender distribution 76.1% female (n=150). Major comorbidities included diabetes (32%), coronary artery disease (CAD) (28.4%), COPD (23.4%), dementia (21.8%), chronic kidney disease (CKD) stage 3 or worse (19.8%), chronic malnutrition (48.7%); 64% used ambulatory or assistive devices pre-fracture. There was a significantly higher prevalence of comorbidities in men - CKD stage 3 or worse (p=0.049), diabetes (p=0.012), CAD (p=0.001). Mortality was 10.7% (n=21), re-hospitalization 13.7%, and 23.4% (n=46) followed up for care. We projected use of osteo-anabolic agents was not feasible in 23.4% of male patients and 32.7% of female patients based on comorbidity. Conclusion Patients with fragility fracture carry a significant disease burden that appears more pronounced in men. Almost a third of female patients, and a quarter of male patients were ineligible for first-line anabolic treatment based on co-morbid conditions, hence detailed clinical workup should inform decision-making for osteoporosis treatment. In addition, there are clearly significant barriers to post-fracture osteoporosis treatment that need to be overcome so as to close the treatment gap.

KY-265, a Novel Benzofuran Derivative, has Osteogenic Effects on Femur Cortical but not Trabecular Bone in Ovariectomized Female Rats *Megumi Yamamoto[1], Masafumi Ando[1], Yuma Ito[1], Masaki Fukui[1], Kazuya Otake[1], Yoshimichi Shoji[1], Eiichi Hinoi[2], Hiroaki Shirahase[1], Tatsuya Kitao[1]. [1]Kyoto Pharmaceutical Industries, Ltd., Japan. [2]Gifu Pharmaceutical University, Japan

Osteoporosis develops due to an imbalance between bone formation via osteoblasts and bone resorption via osteoclasts, and is treated with parenteral and oral resorption inhibitors and parenteral osteogenic drugs. A number of small osteogenic molecules have been reported, which have not been successfully developed. In the present study, we synthesized a novel benzofuran derivative, 3-{4-[2-(2-ethoxyethoxy)ethoxy]phenyl}benzofuran-5-carboxamide (KY-265), and examined its effects on osteoblast differentiation and experimental osteoporosis.Mouse-derived mesenchymal stem cells (ST2) and rat bone marrow mesenchymal stem cells (MSCs) were cultured for 4 days with or without KY-265, and alkaline phosphatase (ALP) activities were determined. Female rats were ovariectomized and orally administered KY-265 at 3 or 10 mg/kg/day for 8 weeks. The femur was scanned using in vivo micro-computed tomography (micro-CT) before OVX and after repeated administrations. Plasma bone-type ALP activity was determined and the isolated femurs were scanned using dual-energy X-ray absorptiometry (DEXA).In ST2 cells and MSCs, KY-265 enhanced ALP activities at 10-7 - 10-5 M, indicating the promoting effects on osteoblast differentiation. In female rats, ovariectomy markedly reduced the uterine weight but had little effect on plasma bone-type ALP activity. In DEXA scanning, ovariectomy reduced areal bone mineral density (aBMD) in distal but not diaphyseal femurs. KY-265 significantly increased distal femur aBMD in ovariectomized (OVX) rats. Micro-CT after administration demonstrated that OVX significantly reduced femur metaphysis trabecular and cortical bone volumes, but not diaphysis cortical bone volume. KY-265 did not affect the reduced metaphysis trabecular bone volume or micro-architectural parameters in OVX rats. On the other hand, KY-265 significantly increased metaphysis cortical bone volume. Changes in micro-CT parameters over the experimental period further suggested that KY-265 promoted cortical but not trabecular bone growth, resulting in an increased cortical bone strength index.The present findings showed that KY-265 has osteogenic effects on cortical bone but not trabecular bone, possibly via promoting osteoblast differentiation, being a potential candidate for bone fracture and osteoporosis therapies.

From Sea to Bone: Marine Sulfated Polysaccharides as Dual Regulators in Bone Remodeling *Jessica S. Landeros-Juárez[1], Enrique Hernández-Garibay[2], Rodrigo Beas-Luna[3], Pierrick Fournier[1], Patricia Juárez[1]. [1]Ensenada Center for Scientific Research and Higher Education, Mexico. [2]Centro Regional de Investigación Pesquera de Ensenada, Mexico. [3]Faculty of Marine Sciences, Autonomous University of Baja California, Mexico

Bones are active living tissue in constant turnover. An imbalance in bone remodeling could lead to bone diseases such as osteoporosis. Nowadays, some therapeutants protect bones from disease or delay the outcome of such pathologies. However, long-term consumption causes adverse side effects. In this work, we characterized the anabolic and antiresorptive effect of a sulfated polysaccharide isolated from three species of brown macroalgae. Chemical characterization of sulfated polysaccharides extracted by acid hydrolysis confirmed that they were mainly composed of fucose (14.5-31.5%), organic sulfates (26.5-41.5%), and uronic acids (42-44%). In mineralization assays on mouse bone marrow cells (BMCs) or preosteoblasts MC3T3-E1, measured with alizarin red staining, the sulfated polysaccharides showed an increase in mineralization as compared to controls after 21 days of culture. In contrast, in osteoclastogenesis assays, sulfated polysaccharides significantly decreased osteoclast formation induced by the cytokines RANKL and M-CSF in a dose-dependent manner. In gene expression studies of osteoprotegerin (OPG) and RANKL, we found a downregulation in the expression of RANKL gene but not OPG. This change in the gene expression ratio RANKL/OPG suggests that sulfated polysaccharides could modulate the bone remodeling process by inhibiting the RANKL signaling pathway.Finally, the effect of sulfated polysaccharides on bone remodeling was evaluated ex vivo using bone calvaria from 4-6-day-old Balb/c mice. After 7 days of culture, the histomorphometric analysis showed that new bone area and the number of osteoblasts increased significantly (i. e. 30-60% and 22-31%, respectively. One-way ANOVA, Bonferroni's Post-test, P>0.05) compared to control-treated calvaria. We demonstrated that sulfated polysaccharides have a dual effect on the bone remodeling process by promoting mineralization and inhibiting osteoclast formation in a dose-dependent manner in vitro. These novel findings suggest that sulfated polysaccharides are anabolic molecules with biomedical potential for treating bone-related diseases.

From bench to bedside: Transcriptome profiling in a medaka fish osteoporosis model identifies CXCL9 as a blood marker that predicts the risk for osteoporotic hip fractures in men *Christoph Winkler[1], Quang Tien Phan[1], Kevin Yiqiang Chua[1], Aizhen Yin[1], Woon-Puay Koh[1], [1]National University of Singapore, Singapore

Bone homeostasis requires reciprocal communication between bone-forming osteoblasts and bone resorbing osteoclasts to maintain bone health. Communication failures result in bone diseases, such as osteoporosis, where uncontrolled osteoclast activity results in excessive bone resorption and bone fractures. To identify novel signalling factors implicated in osteoblast-osteoclast communication, our lab had earlier conducted transcriptome profiling of bone cells in a medaka fish osteoporosis model, which allows high-resolution live imaging of dynamic bone cell behaviour in intact specimen. In this model, transgenic induction of the osteoclast inducer Rankl resulted in excessive osteoclast formation and osteoporotic bone lesions. We showed that under Rankl+ conditions, osteoblasts strongly upregulated expression of the chemokine Cxcl9l. This chemokine in turn led to osteoclast recruitment and differentiation at bone matrix and excessive bone resorption. Mutations in cxcl9l and its cognate receptor cxcr3.2, or treatment with chemical Cxcr3.2 antagonists prevented excessive osteoclast formation and protected medaka bone form osteoporotic lesions. To validate a possible association of the CXCL9 ortholog and osteoporosis or fracture risk in humans, we conducted a matched case-control study nested in the prospective, population-based Singapore Chinese Health Study. This study included 55 men and 119 women who had experienced a hip fracture with an average of 6.3 years after their blood was collected. Participants were matched individually to controls who did not develop hip fractures. We found significantly higher levels of CXCL9 in pre-fracture blood samples of men with subsequent hip fractures compared with their non-fracture controls. Surprisingly, no such differences were seen in women. This suggests that elevated CXCL9 levels affect older men and women differently, possibly due to changes in sex hormone levels during aging. These findings open the possibility that early interventions targeting CXCL9-CXCR3 signalling could be beneficial in preventing hip fractures in older men. This work is funded by a grant from the Singapore Ministry of Education (MOE-T2EP30221-0008).

Spatial and time-dependent inhibition of human osteoclastic bone resorption with cathepsin K inhibitors. A time-lapse study *PREETY PANWAR[1], Jacob Olesen[2], Galia Blum[3], Jean-Marie Delaisse[4], Kent Soe[5], Dieter Bromme[1], [1]University of British Columbia, Canada, [2]University of Southern Denmark, Denmark, [3]The Hebrew University, Israel, [4]Odense University Hospital, KI, University of Southern Denmark, Denmark, [5]Odense University Hospital, University of Southern Denmark, Denmark

Therapeutic approaches that regulate bone resorption by inhibiting cathepsin K (CatK), an essential collagenase in osteoclasts (OCs), have gained attention in past decades. Bone resorption requires a directed OC movement over the bone surface. Using live cell imaging, we monitored the movement and bone resorptive activity of human OCs for 72h and analyzed any change in the resorptive behaviour during dose dependent inhibition of CatK by an ectosteric (T06) and active site-directed inhibitor, odanacatib (ODN). These experiments were performed using 3-5 different human donors and the number of OCs analyzed in each experiment was between 55 and 150. CatK inhibition of OCs by both inhibitors caused drastic changes in resorption speed (Control (147.2 ?m2/h), T06 (500 nM; 42.9 ?m2/h) and ODN (15 nM; 40.3 ?m2/h); $P < 0.0001$). The majority of these CatK-inhibited OCs showed frequent stops (Control; 10% and T06 (1µM; 95%) and ODN (50 nM; 95%); P 80% of the monitoring time. Surprisingly, we also observed frequent fusions of OCs during ongoing bone resorption in control and CatK-inhibited OCs, which both increased their resorption speed up to 10-20%. Fifty percent inhibition of CatK activity displayed a 2-fold increase in OC-fusion ($P < 0.0001$) during ongoing bone resorption, possibly in an attempt to compensate for the CatK-inhibition. Nevertheless, more fusion could not counterweigh the overall loss of resorption speed in the presence of inhibitors. Finally, we were also able to detect the localization of active CatK in bone resorbing OCs by using an activity-based protease inhibitor and confirmed the ectosteric inhibition by T06. In conclusion, with these data we are able to show, using live cell imaging, how OCs respond to CatK-inhibition with respect to movement, bone resorption, and that they seemingly attempt to compensate for inhibition by reactivating fusion.

The beneficial effect of a probiotic mix on bone and lean mass is dependent on the diet in mice. *Klara Sjogren[1], Lina Lawenius[1], Yiwen Jiang[1], Karin Horkeby[1], Jianyao Wu[1], Karin Nilsson[2], Sofia Movérare-Skrtic[3], PETRA HENNING[4], Claes Ohlsson[5], [1]Sahlgrenska Osteoporosis Centre, Sweden, [2], Sweden, [3]Medicine, Sweden, [4]UNIVERSITY OF GOTHENBURG, Sweden, [5]Center for Bone and Arthritis Research at the Sahlgrenska Academy, Sweden

We have previously demonstrated that a probiotic mixture of Lacticaseibacillus paracasei DSM13434, Lactiplantibacillus plantarum DSM 15312 and DSM 15313 (L. Mix) prevents bone loss in ovariectomized (ovx) female mice and postmenopausal women1,2. It is unknown if the beneficial effects of probiotics are modified by the diet. The purpose of the present study is to test if the effects of L. Mix on bone mass is modified by the fat content in the diet.Ten-week-old mice were subjected to either sham or ovx surgery and treated with L. Mix at a concentration of 109 colony forming units/mL or vehicle in the drinking water for 12 weeks. We fed the mice a high fat diet (HFD) with 60% kcal from fat (D12492, Research Diets) or a control low fat diet (LFD) with 10% kcal from fat (D12450J). At the end of the experiment, mice were analysed by dual-energy X-ray absorptiometry (DXA) and dissected bones by peripheral quantitative CT (pQCT).As expected, mice on a HFD had increased body weight and fat % measured by DXA compared to mice on a LFD. L. Mix treatment resulted in higher total body BMD ($p = 0.012$ for the overall treatment effect) and protected mice from loss of BMD after ovx in mice on a LFD but not in mice on HFD (Figure 1). In addition, L. Mix increased total body lean mass in mice on LFD ($p= 0.035$ for the overall treatment effect) but not in mice on HFD. More detailed analysis of the long bones by pQCT showed that L. Mix increased the cortical thickness both in the tibia ($p=0.026$) and femur ($p=0.053$) in mice on LFD but not in mice on HFD.In conclusion, data indicates that the beneficial effect of a probiotic mix on bone and lean mass is dependent on the diet. The LFD may promote the production of some necessary metabolite or cause changes in gut microbiota composition and nutrient absorption. These findings indicate that a combination of certain probiotic bacteria and a healthy diet is beneficial for the musculoskeletal health. Ohlsson, C., et al. PloS one 9 (2014)Jansson, P.A., et al. Sclerostin Loop3-LRP4 Interaction Required by Sclerostin for Antagonizing Wnt Signaling and Osteogenic Potential in Osteoblasts *Luyao Wang[1], Xiaohui Tao[1], Hewen Jiang[2], Ning Zhang[2], Dijie Li[1], Jin Liu[1], Yuanyuan Yu[1], Yihao Zhang[1], Aiping Lyu[1], Baoting Zhang[2], Ge Zhang[1], [1]Law Sau Fai Institute for Advancing Translational Medicine in Bone and Joint Diseases (TMBJ), School of Chinese Medicine, Hong Kong Baptist University, Hong Kong, [2]The Chinese University of Hong Kong, Hong Kong

Sclerostin becomes a novel bone anabolic target. Sclerostin loop2 was reported to bind to YWTD repeats within LRP5/6 of osteoblasts, thereby antagonizing bone anabolic Wnt/?-catenin signaling pathway. Humanized sclerostin antibody which targeted sclerostin loop2 promoted bone formation, whereas imposed sever cardiovascular events in clinical trials. In our published work, sclerostin loop3 was notably found to contribute to the antagonistic effect of sclerostin on bone formation, while the cardiovascular protective effect of sclerostin was independent of loop3. Targeting sclerostin loop3 by our screened sclerostin loop3-specific aptamer promoted bone formation in SOSTki mice, ovariectomized osteoporotic rats and Col1a2+/G610C mice, without increasing cardiovascular risk. The sclerostin loop3 aptamer for osteogenesis imperfecta was granted Orphan Drug Designation by US-FDA (DRU-2019-6966). However, how sclerostin loop3 participates in the antagonistic ef-

fect of sclerostin on bone formation remains unclear. In our pull-down and biolayer interferometry (BLI) studies, sclerostin loop3 was found to bind to LRP4 in osteoblasts (Fig.1a-b). It was reported that osteoblastic LRP4 could facilitate the binding of sclerostin to LRP6 for antagonizing bone formation. After identification of the interaction residues, LRP4m (LRP4-Y200A, G201A, L214A, D215A, I216A, Y217A, H218A, C219A) was designed to genetically block sclerostin loop3-LRP4 interaction in vitro. The antagonistic effect of sclerostin on Wnt signaling and osteogenic potential in osteoblasts were inhibited upon LRP4m, while no changes in Wnt signaling and osteogenic potential were found in the absence of sclerostin before and after expression of LRP4m (Fig.1c-d). Based on the interaction, a peptide tool LRP4-Pep was designed to pharmacologically block sclerostin loop3-LRP4 interaction. The antagonistic effects of sclerostin on Wnt signaling and osteogenic potential in osteoblasts were inhibited after pretreatment of the exogenous LRP4-Pep (Fig.1e-f). Sclerostin loop3-LRP4 interaction was required by sclerostin for antagonizing Wnt signaling pathway and osteogenic potential in osteoblasts in vitro.

Post-prandial timing of PTH treatment alters the osteoanabolic effect in mice *Santosh Thapa[1], Elizabeth Rendina-Ruedy[2]. [1], . [2]Vanderbilt University Medical Center, United States

Osteoporosis and osteopenia are late-onset diseases affecting a staggering 54 million people in the U.S. While anabolic agents that increase bone formation, such as intermittent parathyroid hormone (iPTH), have aided in the management of osteoporosis, patients still experience adverse side-effects. Therefore, continued development of refined therapeutic options is necessary. Our lab and others have recently demonstrated that PTH's osteoanabolic effect relies on exogenous substrates, including fatty acids, to support the energy requirements of bone formation by the osteoblast. As such, we aimed to test the hypothesis that the osteoanabolic actions of iPTH can be enhanced by synchronizing PTH treatment with exogenous substrate availability. The study included 12-week-old male and female C57BL/6NJ mice. A subset of mice experienced standard light/ dark cycle conditions (light 7am-7pm; dark 7pm-7am), while the other subset was acclimated to a reverse light/dark cycle (light 7pm-7am; dark 7am-7pm) regimen. Mice were further divided to receive a subcutaneous injection of PTH (100 µg/kg bodyweight) or vehicle control (Veh) 5 days/ week for 4 weeks. Importantly, treatment injections occurred ~4 hours into the active dark cycle to allow for food ingestion and postprandial substrates circulation. Male mice receiving PTH during their dark cycle demonstrated an increase in BMD as early as 2 weeks following treatment, which was maintained at 4 weeks as well. The increase in BMD was only documented in female mice after 4 weeks of receiving PTH treatment during the dark cycle. There was no detectable difference in bone turnover markers, serum CTx and PINP was elevated in mice receiving PTH, regardless of timing. (C-terminal telopeptide of type I collagen) and PINP (Procollagen type I N-propeptide), in male mice following 2 weeks of treatment in either light/dark cycle. Female mice displayed differences in serum CTx and PINP as early as 2 weeks. By 4 weeks, serum PINP remained elevated in female mice during both light/dark cycle groups. These data are compelling and provide strong evidence that the timing of iPTH treatment can significantly alter the osteoanabolic activity. Ongoing analyses are currently underway to assess bone microarchitecture, histology, and gene expression. Data from this study is expected to enhance clinical applicability and efficacy of the treatment of osteoporosis.

Affinity-targeting of Anti-sclerostin Antibody to the Bone Surface Significantly Increases Therapeutic Efficacy in an Ovariectomy Mouse Model of Osteoporosis *Boya Zhang[2], BEN SWANSON[2], Margaret Durden[3], Megan Weivoda[3], YUJI MISHINA[2], Colin Greineder[2]. [2]University of Michigan, United States. [2]University of Michigan, . [3]Mayo Clinic, United States

Background: We previously demonstrated targeting of globular proteins to the bone surface by site-specific modification with bisphosphonate or deca-aspartate affinity ligands. Bone accumulation of targeted proteins was further enhanced by extending circulation time via Fc-mediated recycling. Proteins anchored to the bone surface were shown to retain activity for at least 24 hours. Here, we extend this work by evaluating the impact of affinity targeting on bone accumulation and retention of anti-sclerostin antibody and determining if improved pharmacokinetics enhance therapeutic effects in a murine osteoporosis model. Methods: Deca-aspartate ligands were fused to the C-termini of murine specific anti-sclerostin antibody (Anti-SOST-D10) and non-therapeutic control IgG (IgG-D10). Blood, organ, and bone pharmacokinetics were determined in 14-week-old female C57BL/6J mice via quantitative radiotracing. Age-matched female mice were subjected to bilateral ovariectomy and treated weekly with i.v. administration of 5 mg/kg anti-SOST-D10, untargeted anti-SOST antibody, IgG-D10, or vehicle. Treatment outcomes were assessed by micro-computed tomography (uCT) phenotype analysis.Results: At 24 hours post-injection, both anti-SOST-D10 and IgG-D10 demonstrated markedly increased biodistribution to bone as compared to untargeted anti-SOST. Furthermore, bone levels of anti-SOST-D10 continued to increase out to 7 days, while anti-SOST decreased steadily to nearly undetectable levels (Figure 1A). In ovariectomized mice, weekly injection of anti-SOST-D10 produced significant increases in BV/TV, as compared to anti-SOST, IgG-D10, and vehicle controls (0.111+/-0.008 vs. 0.074+/-0.006 vs. 0.049+/-0.005 vs. 0.041+/-0.011 for femur, $p < 0.001$, and 0.256+/-0.019 vs. 0.217+/-0.019 vs. 0.170+/-0.017 vs. 0.172+/-0.014 for L4 vertebrae, $p < 0.001$) (Figure 1B). Other indices demonstrated a similar pattern between groups, with significantly increased connective tissue density ($p<0.001$) and decreased SMI in anti-SOST-D10 treated animals ($p<0.001$).Conclusions: Affinity-targeting of anti-sclerostin antibody increased bone accumulation and retention and enhanced therapeutic effects in ovariectomized mice. These results suggest that bone targeting may enable lower doses and longer dosing intervals of anti-sclerostin antibody therapy without reduction in therapeutic efficacy. Future studies will be needed to determine the translational potential of this strategy and its impact on off-target toxicities.

PTH Stabilizes YAP1 in Bone Marrow Stromal Cells through Src-dependent YAP-Tyrosine 428 Phosphorylation to Affect Osteoblast and Adipocyte Differentiation *Sara Monaci[1], Mengrui Wu[2], Roland Baron[3], Dr. Clifford ROsen[4], Francesca Gori[5]. [1]Harvard, United States. [2]Zhejiang University, China. [3]Harvard Medical School and School of Dental Medicine, United States. [4]Maine Medical Center, United States. [5]Harvard School of Dental Medicine, United States

PTH affects mesenchymal cells and cells of the osteoblast (OB) lineage, including osteocytes. Yes-associated protein 1 (YAP) is, together with TAZ, a key transcription factor for the Hippo pathway. YAP can be phosphorylated at various serine residues following its interaction with LATS1/2. This alters YAP cytoplasmic stability through ubiquitination and prevents its translocation to the nucleus to activate the transcription of target genes. Here, we show that in the marrow stromal cell line W20 and in Ocy454 cells, PTH stabilizes YAP, leads to its nuclear translocation, and promotes target gene expression. This effect is mediated through a decrease of YAP interaction with LATS1/2, preventing YAP ubiquitination. Examination of the YAP LATS1/2-binding site residues revealed 2 novel consensus sequences for tyrosine (Y) phosphorylation: Y375 and Y428. To determine Y375 or Y428's role in YAP function and in its stabilization by PTH, we mutated each of these two Y to prevent phosphorylation (Y375F and Y428F). Y428F favored YAP interaction with LATS1/2, leading to major YAP instability. This led to a significant decrease in YAP target genes expression and OB as well as adipocyte (AD) differentiation. We developed an antibody specific for phosphorylated YAP Y428 and showed that PTH induced Y428 phosphorylation. Preventing Y428 phosphorylation (Y428F) increased LATS1/2 binding and serine phosphorylation upon PTH stimulation, decreasing YAP stability and transcriptional activity. PTH-induced Y428 phosphorylation required Src tyrosine kinase activity which, when blocked by dasatinib, prevented PTH effects on YAP stability and on OB and AD differentiation, similar to

Y428F mutation. In contrast, mimicking Y428 phosphorylation (Y428D) restored YAP stability and mimicked the effects of PTH, showing the specificity of the Y428 phosphorylation event. Interestingly, preventing the phosphorylation of Y375 (Y375F) had opposite effects on the responses to PTH. Similar observations on the effects of PTH on YAP stability were made in the Ocy454 osteocyte cell line. These results demonstrate that 1/ PTH stabilizes YAP and allows its translocation into the nucleus by regulating the interaction of YAP with LATS1/2 via Src activation and tyrosine phosphorylation of Y428; 2/ These events regulate the OB and AD differentiation of marrow stromal cells in vitro. Thus, phosphorylation of YAP at specific tyrosine residues is critical for PTH-induced marrow stromal cell differentiation.

11?-Hydroxysteroid Dehydrogenase Type 1 protects against Ovariectomy-induced Osteoporosis by inhibiting Osteoclast Activation *Hao Chen[1], Hanwen Li[2]. [1]Institute of Translational Medicine, The Affiliated Hospital of Yangzhou University, China. [2]The First Affiliated Hospital of Soochow University, China

Objectives: Osteoporosis is a worldwide problem in postmenopausal women and the elderly. 11?-Hydroxysteroid dehydrogenase type 1 (11?-HSD1) is a bi-directional enzyme that primarily activates glucocorticoids (GCs) in vivo, which is a considerable potential target as a treatment for osteoporosis. Previous studies have demonstrated its effect on osteoblasts, while our study aims to demonstrate its role in osteoclastogenesis.Methods: In vivo, we performed ovariectomy-induced osteoporosis (OVX) with 11?-HSD1 global knock-out (KO) mice and the wild type (WT) mice to see the bone phenotypes and osteoclasts number. Furthermore, we generated osteoclastic-specific knockout of 11?-HSD1 mice (Ctsk-cre::11?-HSD1fl/fl) and performed OVX surgery with these mice. Micro-CT analysis, H&E, immunofluorescence staining and qPCR were performed to evaluate the bone phynotypes and osteoclastogenesis. In vitro, bone marrow mesenchymal stem cell (BMSC) and bone marrow-derived macrophages (BMM) of the KO and WT mice were extracted to test their osteogenic and osteoclastogenic abilities. Finally, we conducted the high-throughput sequencing to find out the related genes or signaling pathways to explain how 11?-HSD1 influence osteoclast activation. Results: We found that KO mice were resistant to osteoclast activation and the loss of bone trabeculae. The similar effect was observed in osteoclastic specific knock out of 11?-HSD1 mice. In vitro, we observed the osteoclastogenic ability of the BMM from the KO mice were significantly attenuated. Similarly, BVT-2733, a classic inhibitor of 11?-HSD1, also suppressed the osteoclastogenesis without affecting osteogenic effect. Finally, with high-throughput sequencing, we found that the Hippo signaling was enriched in the 11?-HSD1 induced osteoclastogenic process. Then, the YAP1 activator and inhibitor was used to confirm this, and the results demonstrated that the Hippo signaling was the key as the bridge.Conclusions: Our study revealed that, in the process of osteoporosis, 11?-HSD1 expression in osteoclasts is abnormally increased, which activates osteoclastogenesis and promotes osteoporosis. Hence, 11?-HSD1 might become a new target for treating osteoporosis by cutting off the activation of osteoclastogenesis.

A Longitudinal Study of Bone Strength Development at the Radius and Tibia from Childhood into Adolescence in Children Exposed to Recreational Gymnastics *Marta Erlandson[1], Brendan Ernst[2], Matthew Chapelski[2], Stefan Jackowksi[3], Adam Baxter-Jones[1]. [1]University of Saskatchewan, Canada. [2]University of Saskatchewan , Canada. [3]CHEO Research Institute , Canada

Bone development in childhood and adolescence is important because the bone that is accrued during the early years can have a profound impact on bone health throughout the lifespan. Bone responds to mechanical loading such as that from physical activity (PA). We have previously shown that exposure to recreational gymnastics in early life (4 to 6 years of age) provides skeletal benefits at the distal radius at 7 to 12 years of age; with no differences observed at the radial shaft or tibia. The purpose of this follow-up study was to identify if the positive effects of recreational gymnasts' bone development in childhood (7 to 12 years of age) were maintained into adolescence (11-16 years of age). Methods: In 2006 recreational gymnasts and non-gymnasts, between the ages of 4 and 6 years, were recruited into the Saskatchewan's Young Recreational Gymnast Study (YRGS); a mixed longitudinal study. One hundred and twenty-six children underwent repeated anthropometry, physical activity and dietary assessments, and peripheral Quantitative Computer Tomography (pQCT) scans (distal and shaft sites of the radius and tibia). At the last measurement occasion (2016) children were aged between 11 and 16 years. Multilevel modeling was used to assess the effect of gymnastics exposure on area, density, content, and estimated strength controlling for confounders of growth, maturation, PA, and diet. Results: Gymnastics exposure was a significant independent predictor at the distal radius (4%) on total area (25.43 +/- 6.95mm2), total content (9.58 +/- 2.42mg/mm), total density (14.19 +/- 6.46mg/cm3), trabecular density (13.07 +/- 6.21mg/cm3), and estimated strength (3.17 +/- 1.07mg2/mm4) with a confidence interval of 95% (p0.05). Discussion: Gymnastics exposure during childhood (4 to 6 years of age) significantly predicted improvements at the distal radius during adolescence (11 to 16 years of age). The positive effects of recreational gymnastics at the wrist observed in childhood are seen to be maintained in adolescence when the effects of growth are controlled. The results provided further evidence that exposure to childhood recreational gymnastics exposure is advantageous to bone development at the wrist in adolescence. Funding: Canadian Institute of Health Research, Canadian Foundation for Innovation, and Saskatchewan Health Research Foundation.

Non-Steroidal Anti-inflammatory Drugs are Associated with Increased Risk of Stress Fractures during U.S. Basic Combat Training *Julie Hughes[1], Jeffery Staab[1], Kristin Popp[2], Ian Hussian[1], Leila Walker[1], Ronald Matheny[3], Karl Friedl[1], Stefan Pasiakos[1], Susan Proctor[1], Mary Bouxsein[4], Stephen Foulis[1], Kathryn Taylor[1], Katelyn Guerriere[1]. [1]Military Performance Division, US Army Research Institute of Environmental Medicine, United States. [2]Massachusetts General Hospital, . [3]Military Operational Medicine Research Program, United States. [4]Beth Israel Deaconess Medical Center, Harvard Medical School, United States

Non-steroidal anti-inflammatory drugs (NSAIDs) are prescribed to 80% of soldiers and have been shown to blunt adaptive bone formation from physical activity which may predispose to stress fracture during physically rigorous military training. In a retrospective analysis of trainees undergoing U.S. Army Basic Combat Training (BCT), stress fracture risk was five-fold higher in those prescribed NSAIDs compared to those who were not. These results have not been confirmed in a prospective study of BCT. Whether the frequency of NSAID use modulates their association with stress fracture risk has not been studied. Trainees volunteered for a prospective observational study of injury risk factors during BCT and completed weekly surveys during BCT describing NSAID use. ICD-10 codes were used to identify stress fractures during BCT. Multivariate logistic regressions, adjusted for age, sex, race/ethnicity, BMI, and the number of weekly surveys collected, were used to assess the relationship between NSAID use and stress fracture risk during BCT. NSAID use during BCT was evaluated in three ways: ever used (yes/no), average number of days used per week (continuous), total weeks used during BCT (continuous). To account for reverse causation, NSAIDs exposure was lagged by excluding NSAID use two weeks before stress fractures were diagnosed. Of 2,482 participants (mean+/-SD; age=20.7+/-3.7, BMI= 24.7+/-3.5), 62% were male, 44% were Non-Hispanic White, and 24% were Non-Hispanic Black. We identified 49 trainees with at least one diagnosed stress fracture during BCT (16 men, 33 women). Stress fracture risk was greater for NSAID users compared to nonusers (odds ratios(95%CI)); 4.9(2.2,10.9). In men, stress fracture risk was 3.6-fold (2.3,5.5) greater for every 1-day increase in the average number of days NSAIDS were used per week and 2.1-fold (1.5,3.0) greater for each additional week NSAIDs were used. There were no significant relationships between the frequency of NSAID use and stress fractures in women. Stress fracture risk during BCT was nearly 5-fold greater in trainees using NSAIDs than those who were not. In men, stress fracture risk increased progressively when the frequency of NSAIDs use also increased. These results corroborate previous results and provide further evidence to recommend conservative approaches to NSAID prescriptions during BCT.

Is There a Causal Relationship Between Physical Activity and Bone Microarchitecture? A Study of Adult Female Twin Pairs *Frida Nissen[1], Vivenne F C Esser[2], Minh Bui[3], Shuai Li[3], John Hopper[3], Ashild Bjornerem[4], Ann Kristin Hansen[5]. [1], . [2]BHlthMedSc(Hons), Australia. [3]PhD, Australia. [4]UiT The Arctic University of Norway, Norway. [5]MD PhD, Norway

The reasons for the association between physical activity (PA) and bone microarchitecture traits are unclear. We examined whether these associations were consistent with causation and/or with shared familial factors using a cross-sectional study of 47 dizygotic and 93 monozygotic female twin pairs aged 31-77 years. Images of the nondominant dis-

tal tibia were obtained using high-resolution-peripheral quantitative computed tomography. The bone microarchitecture was assessed using StrAx1.0 software. Based on a self-completed questionnaire, a PA index was calculated as a weighted sum of weekly hours of light (walking, light gardening), moderate (social tennis, golf, hiking), and vigorous activity (competitive active sports) = light + 2*moderate + 3*vigorous. We applied Inference about Causation through Examination of FAmiliaL CONfounding (ICE FALCON) to test whether cross-pair cross-trait associations changed after adjustment for within-individual associations. Within-individuals distal tibia cortical cross-sectional area (CSA) and cortical thickness were positively associated with PA (regression coefficients (?) = 0.20 and 0.22) while porosity of the inner transitional zone was negatively associated with PA (? = -0.17), all p < 0.05. Trabecular vBMD and trabecular thickness were positively associated with PA (? = 0.13 and 0.14), and medullary CSA was negatively associated with PA (? = -0.22), all p <= 0.01. Cross-pair cross-trait associations of cortical thickness, cortical CSA and medullary CSA with PA attenuated after adjustment for the within-individual association (p = 0.048, p = 0.062 and p = 0.028 for changes). In conclusion, increasing PA was associated with thicker cortices, larger cortical area, lower porosity of the inner transitional zone, thicker trabeculae, and smaller medullary cavities. The attenuation of cross-pair cross-trait associations after accounting for the within-individual associations were consistent with PA having a causal effect on the improved cortical and trabecular microarchitecture of adult females, in addition to shared familial factors.

The Influence of Eight Months of Ballistic and Conventional Resistance Exercise Training on Bone Mineral Content in Postmenopausal Women: The REPROOF Study *Ogulcan Caliskan[1], Elisa Marques[1], Jonathan Folland[1], Katherine Brooke-Wavell[1]. [1]Loughborough University, United Kingdom

High load, progressive resistance training is recommended for osteoporosis prevention and management, but the effectiveness of lower load, higher velocity exercise on BMD is unclear. Fast ballistic resistance exercise involves moving as explosively as possible with a light/moderate load, attempting to launch the load, if possible, to maximise rate of force development. The aim was to investigate the influence of ballistic and conventional resistance training, relative to control, on BMC and BMD in postmenopausal women.The Resistance Exercise Programme on Risk of Osteoporosis and Osteoarthritis in Females (REPROOF) study was an eight-month randomised controlled trial. Participants were healthy women aged 50-75 years, >4 years postmenopause and without osteoporosis or other conditions/medications affecting bone. They were randomly allocated to ballistic resistance training (BRT), conventional resistance training (CRT) or control (CON) groups. Both RT groups attended similar twice-weekly training sessions, including warm-up and resistance exercises (hack squat and unilateral calf raise). The heaviest weight that could be lifted for one repetition maximum (1RM) was determined monthly and used to progressively increase the load. This ranged up to 50%1RM in BRT and the maximum load that could be lifted 8 times in CRT. Both hips and lumbar spine were measured by dual X-ray absorptiometry(GE iDXA). Mean femoral neck, total hip and lumbar spine BMC and BMD were the main and secondary outcomes, respectively. Comparisons between groups were made using linear regression models adjusting for baseline values.111 of 133 screened women were randomised (38 BRT, 39 CRT and 32 CON) of whom 82 (28 BRT, 29 CRT and 25 CON; 63.1+/-3.7 years; 24.5+/-3.5 kgm-2; femoral neck T-score -1.0 and lumbar spine T-score -0.8) completed the study and were included in the analysis. Mean adherence was 98.3%in BRT and 98.0% in CRT. BRT improved total hip BMC by mean (95%CI) 0.33 (0.07, 0.59) g (p=0.01) and BMD by 0.008 (0.001, 0.014) g cm-2 (p=0.02) relative to CON (Figure1). There were no other statistically significant differences between groups.Ballistic resistance training increased total hip BMC and BMD, whilst conventional resistance training did not. This contrasts with previous findings that high load resistance training is necessary for skeletal adaptation. Ballistic resistance exercise was feasible in healthy postmenopausal women and may have a role in osteoporosis prevention.

Applying novel analytic methods to 24-hour physical activity and sleep behaviors to determine associations with HR-pQCT parameters at the distal limbs in older adults: The Study of Muscle, Mobility and Aging (SOMMA). *Lauren S. Roe[1], Tong Yu[6], Nina Heilmann[6], Nicole M. Sekel[3], Kristen Koltun[6], Julie Hughes[4], Katelyn I. Guerriere[5], Kerri Freeland[6], Peggy Cawthon[7], Nancy W. Glynn[8], Kelley Pettee Gabriel[9], Bradley Nindl[3], Paolo Caserotti[10], Elsa Strotmeyer[6], Jane A. Cauley[11]. [1], [6]University of Pittsburgh, [3]2Neuromuscular Research Laboratory/Warrior Human Performance Research Center, Department of Sports Medicine and Nutrition, University of Pittsburgh, United States. [6]University of Pittsburgh, United States. [7]San Francisco Coordinating Center, United States. [8]University of Pittsburgh School of Public Health, Department of Epidemiology, United States. [9]Department of Epidemiology, The University of Alabama at Birmingham, United States. [10]Department of Sports Science and Clinical Biomechanics and the Center for Active and Healthy Ageing, University of Southern Denmark, Denmark. [11]UNIVERSITY OF PITTSBURGH, United States

Optimal time in moderate to vigorous intensity activity (MVPA), light intensity activity (LPA), and sleep are critical for bone health in older adults but are often considered separately. Given the finite 24-hrs in a day, MVPA, LPA, sedentary behaviors (SB), and sleep are inherently co-dependent. We examined associations between the composition of accelerometer-derived MVPA [>3940 vector magnitude counts (vcm)/min], LPA (2860-3940 vcm/min), SB (<2860 vcm/min), and sleep with High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) measures. This study included community-dwelling older men (n=105) and women [n=167; mean age: 76.2+/-4.52 yrs (same for men and women)] enrolled in the Study of Muscle, Mobility and Aging (SOMMA) Bone Ancillary Study. Participants wore an ActiGraph GT9X on their nondominant wrist for five 24-hr periods after the SOMMA baseline visit. At the 12-mo visit, distal radius (DR) and tibia (DT) estimated failure load, total volumetric bone mineral density (vBMD), and cortical and trabecular vBMD, bone area, and thickness were obtained from HR-pQCT. Compositional data analysis methods were applied to estimate associations between 24-hr movement profile (distribution of MVPA, LPA, SB, and sleep) with sex-specific standardized HR-pQCT parameters in linear regression models for men and women separately. Isotemporal compositional substitution methods were applied to estimate hypothetical changes in predicted continuous HR-pQCT measures (not standardized) if 30 minutes of MVPA displaced 30 minutes of SB. Mean composition of MVPA, LPA, SB, and sleep for men was 159, 95, 755, and 431 min/day, and for women was 206, 104, 687, and 442 min/day. In minimally adjusted models (age and race), the 24-hr movement profile was associated only with DR cortical area (Ct.Ar) in men (p=0.047), and DR trabecular thickness (Tb.Th) in women (p=0.01). Subsequent adjustment for ulna length, body mass index, and smoking status did not change results (p-values: for Ct.Ar=0.046, for Tb.Th=0.006). Theoretically displacing 30 min of SB for 30 min of MVPA increased the predicted Ct.Ar for men by 0.56 mm2 (mean: 74.48 vs. 75.04 mm2) and Tb.Th for women by 0.002 mm2 (mean: 0.23 vs. 0.24 mm2). Replacing SB with MVPA was related to improved Ct.Ar and Tb.Th at the non-weightbearing DR, a robust predictor of clinical and

major osteoporotic fractures, but no association were found between 24-hr activity composition with HR-pQCT measures at the weightbearing DT.

SUN-479

The Effect of 9 Months Whole Body Vibration, With or Without Osteogenic Exercise, on Indices of Bone Strength and Fracture Risk: the VIBMOR Trial *Belinda Beck[1], clinton rubin[2], Mark Forwood[1], Amy Harding[1], Luke Buizen[3]. [1]Griffith University, Australia. [2]State University of New York at Stony Brook, United States. [3]University of New South Wales, Australia

PurposeThe purpose of the VIBMOR randomised controlled trial was to determine the efficacy of low-intensity whole-body vibration (LIV), bone-targeted, high-intensity resistance and impact training (HiRIT), or the combination of LIV and HiRIT, on risk factors for hip fracture in postmenopausal (PM) women with osteopenia and osteoporosis.MethodsPostmenopausal women with low aBMD at the hip or spine, with or without a history of fragility fracture and on or off antiresorptive osteoporosis medications (OP meds), were recruited. Exclusions included: cognitive impairment, uncontrolled cardiovascular disease, anabolic bone medications, regular HiRIT or LIV in preceding 12 mths, malignancy, current or recent chemotherapy, conditions and medications adversely influencing bone health, recent fragility fracture, and unable to undertake 9 mths 2/wk supervised exercise training. Participants were randomly allocated to 9 mths of either LIV, HiRIT, LIV+HiRIT, or control (low-intensity home exercise) followed by 12 mths detraining. Allocation was block-randomized, stratified by use of OP meds. Testing occurred at baseline (T0), 9 mths (T1) and 21 mths (T2). The primary outcome was total hip aBMD (DXA, Norland Elite). Secondary outcomes included anthropometrics, aBMD at the spine, femoral neck, trochanter and whole body, 3D hip and pQCT indices of bone strength, lean and fat mass, functional performance, posture, muscle strength and power, balance, falls, and intervention compliance. Exploratory outcomes included bone turnover markers, pelvic floor health, quality of life, physical activity enjoyment, adverse events, and fracture. An economic evaluation was conducted. ResultsData collection was finalised Dec 2022 and data entry/cleaning was completed April 2023. Total study n was 252 (Con 62, LIV 64, HiRIT 61, LIV+HIRIT 65). Mean age was 68.7 +/- 7.0 yrs, height 160.4 +/- 11.9 cm, weight 64.1 +/- 11.9 kg and LS BMD T-score -1.2 +/- 1.0. Compliance with each intervention was CON 80.5 +/- 29.9%, LIV 85.1 +/- 21.3% and HiRIT 78.9 +/- 12.1%. Our submission is an 'initiated trial abstract' per the Abstract guidelines. Full data analysis is underway and results will be available by the ASBMR Annual Meeting.ConclusionsThe VIBMOR trial is the first to compare the effect of LIV alone or in combination with HiRIT on risk factors for hip fracture in PM women with low bone mass. Findings are highly relevant to those with low bone mass who are unwilling to take or adversely affected by OP meds.

Clinical Outcome Assessment Instruments for Neurofibromatosis Type 1 (NF1)-Related Skeletal Manifestations: A Targeted Literature Review *Ayo Adeyemi[1], Maria Marfa[2], Inga Gru?[3], Gail Doughton[4], Damien Simoneau[5]. [1]Alexion, AstraZeneca Rare Disease, Boston, MA, USA, United States. [2]Alexion, AstraZeneca Rare Disease, Barcelona, Spain, Spain. [3]IQVIA, New York, NY, USA, United States. [4]Alexion, AstraZeneca Rare Disease, Cambridge, UK, United Kingdom. [5]Alexion, AstraZeneca Rare Disease, Zurich, Switzerland, Switzerland

Purpose: People with NF1 can experience skeletal manifestations (SM), e.g. scoliosis; however, no approved pharmacotherapies for SM are currently available. To inform future clinical study design, identification of fit-for-purpose clinical outcome assessments (COA) is needed. Here, we aimed to develop a conceptual model to assess signs, symptoms and impacts of NF1-related SM. Then, the landscape of COAs used for NF1-related SM was reviewed to identify potential fit-for-purpose tools in this population.Methods: Information from a targeted literature review was used to create a preliminary conceptual model of the patient experience and identify relevant instruments for measuring these concepts. Information on content validity and psychometric criteria were included. Four sources were queried: published literature (PubMed, Cochrane Library and Embase), clinical trials, PROQOLID™, and PROLABELS™. Searches included disease and outcome-related terms and were limited to human studies in English with available abstracts, published <=10 years prior.Results: The conceptual model identified scoliosis as a core sign/symptom of NF1-related SM, with impacts on emotional, physical, social and general wellbeing. Across the 4 sources, 156 unique COAs relevant to NF1 were identified, of which 5 were related to SM: Scoliosis Research Society (SRS) Patient Questionnaire (v7 and 22), Early Onset Scoliosis 24-item Questionnaire (EOSQ24), Neck Disability Index (NDI), and Japanese Orthopedic Association (JOA) Scoring System. SRS instruments were the most relevant tools available to measure symptoms and impacts specific to scoliosis. Although the EOSQ24 focuses on measuring impacts, it does not cover signs/symptoms specific to SM. The NDI and JOA partially cover symptomatic cord compression/myelomalacia and cervical compression myelopathy, respectively. Other NF1-related and general quality of life tools were identified to better support concepts in the conceptual model: INF1-QOL and PedsQL NF1, and PedsQL core module. The content validity and psychometric properties of the tools were mostly seen as low as it relates to SM in patients with NF1.Conclusions: The signs, symptoms, and impacts of SM are varied and not covered comprehensively by any single instrument. The use of a combination of instruments, including generic tools maybe considered to capture the several domains of patient quality of life impacted by NF1-related SM.

SUN-481

Changes in Volumetric Bone Mineral Density and Microarchitecture in Adults With X-linked Hypophosphatemic Rickets: a Longitudinal Case Control Study *Thomas Funck-Brentano[1], Arnaud Vanjak[2], Agnes Ostertag[3], Corinne Collet[2], Bert Rietbergen[4], MARTINE COHEN-SOLAL[5]. [1]Univserité de Paris, France. [2]Université Paris Cité INSERM U1132 Bioscar, France. [3]INSERM U1132 Biscar, France. [4]Eindhoven University of Technology, Netherlands. [5]Inserm U1132 Bioscar and université Paris-Cité, France

X-Linked Hypophosphatemia (XLH) is the most common type of inherited rickets. Although the clinical features of this rare disease are well characterized, bone mineralization, microstructure and biomechanical changes over time are poorly known. Our aim was to analyze changes in bone properties assessed by High Resolution peripheral Quantitative Computed Tomography (HRpQCT) in the appendicular skeleton of adults with XLH. At baseline, each XLH patient (N= 14 adults; 9 females; age 50 +/- 15 years) was matched by sex, age and body mass index to a minimum of two healthy controls (N= 34). Patients and their matched controls were assessed by DXA and HRpQCT at baseline. Each continuous variable was compared between XLH patients and their matched controls using a paired T-test with multiple controls, according to the method described by Ury et al. Nine XLH patients were then followed for a median duration of 4 years with a new HRpQCT evaluation. For HR-pQCT, we evaluated 12 parameters at the tibia and the radius. After Bonferroni correction for multiple testing, a P value < 4.2x10-3 was considered significant. All participants gave their written consent to participate to the study and ethical approval was obtained by the local ethical committee.HRpQCT demonstrated that total volumetric BMD was decreased at the radius (mean difference -87.85 mgHA/cm3 +/- 22.24, P=0.001). Cortical thickness was decreased (-165.27 µm +/- 48.42, P=0.002) was with a preserved Cortical area in relation to an increased total area due to metaphyseal enlargement. A trend in trabecular bone volume fraction was also observed lower with fewer trabecular number (-0.60/mm² +/- 0.10, P<0.001). However, bone strength evaluated by micro-finite element analyzes revealed unaffected bone stiffness and maximum failure load. Similar trends were observed at the tibia. At follow-up cortical vBMD had further decreased at the tibia (-33.44 mgHA/cm3 +/- 25.65, P=0.004) as well as total vBMD (P nominal =0.02). Analysis of bone microarchitecture revealed a decreased cortical area and increased trabecular area suggesting of cortical trabecularisation over time. However, no significant change was observed at the radius.In adult XLH patients, bone mineral density and microarchitecture is impaired at the appendicular skeleton. With time, alterations of mineralization and microarchitecture worsen. The impact of secondary hyperparathyroidism on these changes could not be analyzed in this pilot study. The respective impact of conventional or targeted therapies for XLH should be further assessed in the future.

New Heterotopic Ossification Lesions in Patients with Fibrodysplasia Ossificans Progressiva Measured by PET/CT vs CT Only *Dinko Gonzalez Trotter[1], Jennifer McGinniss[1], Aris Economides[1], Kusha Mohammadi[1], Andrew Rankin[1], Bret Musser[1], Scott Mellis[1], Eduardo Forleo-Neto[1], Gary Herman[1]. [1]Regeneron Pharmaceuticals, Inc., United States

Purpose: Fibrodysplasia ossificans progressiva (FOP) is an ultra-rare disorder caused by mutations in the activin-A receptor type 1 (ACVR1) gene that render it responsive to activin-A. FOP is characterized by the deposition of bone in soft tissues known as heterotopic ossification (HO) and episodic painful flare-ups. Garetosmab, a fully human monoclonal antibody against activin-A, is being investigated for the prevention of new HO lesions in patients with FOP.Methods: This post hoc analysis compared the change from baseline in the number and volume of new HO lesions identified by 18F-labeled sodium fluoride (a bone-seeking tracer that measures bone deposition and turnover) positron emission tomography (PET) and X-ray computed tomography (CT) imaging (measures bone volume). Baseline and 28-week PET/CT and CT-only scans acquired during the initial double-blind, placebo-controlled period of the LUMINA-1 (NCT03188666) phase 2 study were independently read by two sets of blinded readers and an adjudicator for the presence and volume of new lesions. Number and volume of new lesions were compared between the two imaging modalities.Results: The number of patients with new lesions as detected by PET/CT and CT only was 14/44 (31.8%) and 12/44 (27.3%), respectively. The mean number (standard deviation) of new lesions per patient by PET/CT through Week 28 was 0.68 (1.57) vs 0.86 (1.95) detected by CT only. In patients with new lesions, the mean number of new lesions per patient was 2.14 (2.18) vs 3.17 (2.62) as detected by PET/CT vs CT only, respectively. The mean volume (cm3) of new lesions through Week 28 per patient detected by PET/CT was 6.05 (14.88) vs 5.94 (21.13) by CT only. In the subset of patients with new lesions, the mean volume of new lesions per patient detected by PET/CT was 19.02 (21.60) vs 21.79 (36.98)

by CT only. Moderate agreement between PET/CT and CT only detection was observed when identifying patients with new lesions, with a kappa coefficient of 0.46 (standard error: 0.146; 95% confidence interval: 0.17-0.74). Placebo vs garetosmab groups, respectively, showed aggregate new lesion number/volume (cm3) of 27/245.3 vs 3/21.3 by PET/CT, and 37/261.8 vs 1/0.1 by CT only.Conclusions: CT only imaging showed similar performance to PET/CT in the detection and characterization of new HO lesions and provides a viable option for the assessment of therapies that may inhibit the formation of new HO lesions in patients with FOP.

Bone microarchitecture and strength in Osteogenesis Imperfecta using HR-pQCT: comparison with normative data taking into account limb length and deviating axial scan angles *MELISSA BEVERS[1], Bert Rietbergen[2], Arjan Harsevoort[3], Koert Gooijer[3], Hans Feenstra[3], Guus Janus[3], Caroline Wyers[4], Joop Van Den Bergh[5]. [1]VieCuri Medical Center, , [2]Eindhoven University of Technology, Netherlands. [3]Expert Center for adults with Osteogenesis Imperfecta Isala Hospital, Netherlands. [4]VieCuri Medical Centre, Netherlands. [5]VieCuri MC Noord-Limburg and Maastricht UMC,

Purpose: Patients with osteogenesis imperfecta (OI) have increased bone fragility and fracture risk. High-resolution peripheral quantitative CT (HR-pQCT) has been used to study bone microarchitecture in OI as compared to non-OI groups, but short stature and bone deformities in OI may cause deviations in scanned region and limit comparison. The aim of this study was to assess bone microarchitecture and strength in adults with OI as compared to normative data using HR-pQCT with a limb-length dependent scan protocol and by taking into account deviating scanned regions. Methods: Limb-length dependent HR-pQCT scans of the distal radius and tibia were obtained from 118 adults with OI (41.8 [IQR: 25.1] year old). To evaluate potential deviations in the scanned region, the axial scan angle was computed using a new algorithm that quantifies the angle between the areal center of the bone on the first and last slice of a scan. The angle was compared to that of limb-length dependent HR-pQCT scans of 13 healthy young women. It was considered to be deviated when being outside the fence of 1.5xIQR from Q1 and Q3 in those women. Bone microarchitecture and strength were quantified and compared to normative data from literature (Warden et al. Osteoporos Int 2021). Results: 102 radius and 105 tibia scans could be analyzed, of which the axial scan angle was found to be deviating in 11 (radius; 10.8%) and 14 (tibia; 13.3%). In the radius scans without deviating angle, total BMD was low (Z-score: -1.0+/-1.8) as were trabecular BMD (Z-score: -1.6+/-1.3) and number (Z-score: -2.5+/-1.4) and total bone stiffness (Z-score: -1.4+/-1.5). Trabecular separation was high (Z-score: -2.7 [2.7]). Trabecular thickness and cortical BMD and microarchitecture were normal. Larger deviations were seen at the tibia. In the scans with a deviating axial angle, deviations from the normative data were smaller or similar (cortical bone) but more often larger (total and trabecular bone) than in the scans without deviating angle, most pronounced at the tibia (Fig.1). Conclusion: Bone microarchitecture and strength in OI are impaired, in particular at the trabecular compartment. It likely contributes to the increased fracture risk in OI and may provide valuable insights to improve treatments of reduced bone quality. Scans with a deviating scanned region, likely due to bone deformities and scan positioning limitations in OI, should be excluded in HR-pQCT studies on OI, especially when comparing study groups.

	Non-deviating	Deviating	Non-deviating	Deviating
Z<-1	51 (56%)	9 (82%)	78 (86%)	14 (100%)
Z<-4	4 (4%)	1 (9%)	5 (5%)	7 (50%)

SUN-486

New Insights into the Skeletal Consequences of Trisomy 21 from the Plasma Metabolome and Lipidome of Patients *COLE DAHLSTROM[1], ALYSSA FALCK[2], KIRBY M. SHERMAN[3], Matthew Galbraith[4], Joaquin Espinosa[4], Dana Gaddy[5], Larry Suva[6]. [1]Texas A&M University, , [2], United States. [3]Texas A&M University , , [4]Colorado University- Anschutz, United States. [5]College of Veterinary Medicine, Texas A&M University, United States. [6]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States

Bone turnover is a complex and coordinated activity that results from two processes: bone resorption and new bone formation. CTX-I and P1NP are biochemical markers of bone resorption and formation that we measured in a series of bisphosphonate-naïve individuals diagnosed with trisomy 21 (Ts21) (20 female; 20 male, n=40) and control age-matched patients (20 female; 20 male, n=40). Ts21 females had significantly increased CTX-I (p=0.0442); however, once corrected for vitamin D and thyroid hormone status, no significant differences were observed. However, age stratification of patients revealed a significant and sustained decline in both CTX-1 and P1NP in female Ts21 patients between ages 20 and 40 (p=0.02) that was not observed in control. No significant correlations were observed in males with Ts21, indicative of sexual dimorphism in bone turnover markers in Ts21 patients. We next performed a detailed metabolomic analysis of plasma from these patients using Vanquish UHPLC coupled online to a Q Exactive high resolution mass spectrometer. Profiles were analyzed using Maven in conjunction with the KEGG database and the metabolomic profiles correlated with measured CTX-1 and P1NP levels. Several fatty acid (FA) metabolites (e.g. palmitic acid, acylcarnitine) had strong positive correlations with P1NP in control patients (p=0.0225 & p=0.001 respectively) but were not correlated in Ts21, suggesting that Ts21 osteoblasts may have alterations in their energy utilization of FAs. Similarly, aspartate and glutamine, which are both required for mitochondrial energy production, were diminished in plasma from patients with Ts21 compared to control, supporting the conclusion of mitochondrial dysregulation in Ts21. Furthermore, metabolites that impact bone cell function such as tauroursodeoxycholic acid and picolinic acid (both known to be bone anabolic) were positively correlated with P1NP levels in control but not Ts21 (p=0.0008 & p=0.0045 respectively), further implicating systemic diminution of osteoblast activity in Ts21 patients. Collectively, these studies provide new insight into the circulating metabolome of Ts21 patients and suggest that both osteoclast (CTX-I) and osteoblast (P1NP) activity may be compromised when disconnected from bone-promoting circulating metabolites. As Ts21 patients age, the continued miscommunication between the metabolome and bone cell function is likely contributing to the increased fracture risk that we and others have reported.

A Prospective Study to Evaluate Patient-Reported Quality of Life Before and After Asfotase Alfa Treatment in Adults with Pediatric-Onset Hypophosphatasia *Kathryn Dahir[1], Steven Ing[2], Chad Deal[3], Andrew Messali[4], Toby Bates[4], Eric T. Rush[5]. [1]Vanderbilt University Medical Center, United States. [2]The Ohio State University Wexner Medical Center, United States. [3]Cleveland Clinic Foundation, United States. [4]Alexion, AstraZeneca Rare Disease, United States. [5]Children's Mercy Kansas City; University of Missouri - Kansas City School of Medicine, United States

Purpose: To evaluate the impact of asfotase alfa on patient-reported outcomes (PROs) in adults with pediatric onset hypophosphatasia (HPP).Methods: A longitudinal telephone-based survey was administered to adults with pediatric-onset HPP at baseline (prior to asfotase alfa initiation) and follow-up (3 [3M], 6 [6M], and 12 months [12M] post-initiation). Demographics and PROs (Patient Health Questionnaire-9 [PHQ-9], Patient-Reported Outcomes Measurement Information System [PROMIS-29], Routine Assessment of Patient Index Data 3 [RAPID3], and Work Productivity and Activity Impairment-Specific Health Problem [WPAI-SHP]) were assessed (Figure). McNemar's or Cochran-Mantel-Haenszel tests or paired t-tests were performed, as appropriate.Results: Among 50 enrolled patients, 29 were evaluable at 12M. Mean age at baseline was 46 (+/-15.4) years; 80% were female and 94% were White. At 12M, a statistically significant improvements from baseline were observed for PHQ-9 total score (10.6 baseline vs 4.2 12M, P<0.0001), PROMIS-29 domain scores (physical functioning: 38.0 vs 46.5, P<0.0001; anxiety: 57.5 vs 47.9, P<0.0001; depression: 52.6 vs 47.4, P=0.003; fatigue: 63.3 vs 51.3, P<0.0001; sleep disturbance: 58.8 vs 51.6, P=0.0008; social roles and activities: 42.6 vs 50.7, P=0.0001; pain interference: 63.8 vs 54.9, P<0.0001), and RAPID3 domain scores (functional status: 2.7 vs 1.1, P<0.0001; pain tolerance: 6.0 vs 3.2, P<0.0001; global health estimate: 5.1 vs 2.7, P<0.0001). WPAI-SHP domains showed significant improvement at 12M in presenteeism (39.6% vs 14.0%, P<0.0001), activity impairment (64% vs 30.0%, P<0.0001), and work productivity loss (41.9% vs 20.0%, P=0.012); however, the significant improvement seen at 6M in absenteeism (4.7% vs 0%, P=0.025) was not maintained at 12M (vs 8.0%, P=0.65). By 12M, the use of analgesic medications decreased from baseline (20%, n=10 vs 10.3%, n=3).Conclusion: Treatment with asfotase alfa improved anxiety, depression, physical functioning, fatigue, sleep, pain, and improved work and social relationships. These results illustrate the potential utility of adapting existing PRO instruments validated in diseases phenotypically similar to HPP.

SUN-488

A 14-day repeated oral administration of meclizine in child patients with achondroplasia to evaluate safety and pharmacokinetics *Masaki Matsushita[1], Kenichi Mishima[1], Yasunari Kamiya[1], Kenta Sawamura[1], Hiroshi Kitoh[2], Shiro Imagama[1]. [1]Nagoya University Graduate School of Medicine, Japan. [2]Aichi Children's Health and Medical Center, Japan

Achondroplasia (ACH) is a skeletal dysplasia characterized by shorten-limbed short stature. We employed a drug repositioning strategy and found meclizine, which has been used as an anti-motion sickness for more than 50 years, inhibited the fibroblast growth factor receptor 3 (FGFR3) signalings. Meclizine also revealed enhancing bone growth in a mouse model of ACH, and the plasma concentration of meclizine was lower than that for anti-motion sickness. A previous single-dose study of meclizine 25 and 50 mg for child patients with ACH showed no serious adverse events. According to the instruction of Pharmaceuticals and Medical Devices Agency, we performed additional pre-clinical studies using rats and dogs, including 2-week-repeated dose toxicity studies, toxicokinetic and pharmacokinetics (PK) studies, genotoxicity studies, safety pharmacology, pharmacodynamic studies, and juvenile animal toxicity studies. Thus, we conducted current study to evaluate the safety and PK for child patients with ACH after a 14-day-repeated dose of meclizine. Current study enrolled twelve patients with ACH, aged 5-10 years. Patients were randomly divided into meclizine 12.5 mg/day group (n = 6) and 25 mg/day group (n = 6), and they took meclizine after meals for 14 days. The adverse events (AEs) and PK were assessed. The patients were subjected to blood sampling immediately before drug dosing and at 1, 2, 3, 4, and 6 h after dosing on Days 1 and 14, and 10 and 24 h on Day 14 for PK evaluation. No patients experienced serious AEs in either group. The average maximum drug concentration (Cmax), peak drug concentration (Tmax), area under the curve (AUC0-24h), and terminal elimination half-life (t1/2) on Day 14 of meclizine 12.5 and 25 mg were 167 and 266 ng/mL, 3.7 and 2.8 h, 1170 and 1780 ng·h/mL, and 7.4 and 7.9 h, respectively. Cmax and AUC were increased in a dose-dependent manner. AUC0-6h on Day 14 was 1.5 times that on Day 1. The AUC0-24h on Day 14 revealed negatively correlation with patient weight. As proposing regimen of meclizine 12.5 and 25 mg in patients weighting <20 kg and >=20 kg, respectively, the coefficient of variation value for AUC0-24h was reduced from 54 to 21%. Compartment models demonstrated that the plasma concentration of meclizine achieved at steady state on Day 14. Meclizine 12.5 or 25 mg/day depending on the patients' weight is recommended for long-term administration of phase 2 clinical trial in child patients with ACH.

[5]University of Alberta,

X-linked Hypophosphatemia (XLH) is associated with elevated fibroblast growth factor 23 (FGF23) resulting in renal phosphate wasting and decreased 1,25 dihydroxyvitamin D. It is a multi-system disease with significant co-morbidities. Current treatment options include conventional therapy (phosphate and 1,25 dihydroxy vitamin D) or burosumab (anti-FGF23 therapy). High rates of hypertension (HTN) have been reported in adults, but it is unclear if HTN develops in childhood. We present data on HTN in pediatric XLH.Methods: We evaluated medical records of children (<18 years of age) with XLH followed at two tertiary care centers, the Stollery Children's Hospital (Edmonton, Canada), and the Children's Hospital of Los Angeles (Los Angeles, United States) from 2014-2022. Patients were included if they had three or more blood pressure (BP) recordings. Clinical data was collected including laboratory and treatment data and renal ultrasound results. HTN was defined as systolic or diastolic BP (SBP, DBP) greater than the 95th percentile for age, sex and height on three or more occasions, as per the Fourth Report on the Diagnosis, Evaluation, and Treatment of High Blood Pressure in Children and Adolescents. Descriptive analyses were performed. Results: Our cohort included 56 children (35 female, 63%) with XLH. HTN was found in 19 children (34% of the cohort, n=10 female), diagnosed at a mean age of 7.9 years (SD 4.2). SBP was higher than DBP with a SBP percentile average of 76 and DBP percentile average of 58 ($p<0.01$). 14 children had isolated systolic HTN, 4 had a combination of diastolic and systolic HTN, and 1 child had isolated diastolic HTN. HTN was not associated with body mass index, serum parathyroid hormone levels, nephrocalcinosis, or average weight-based phosphate or 1,25 dihydroxyvitamin D treatment over the study period. Furthermore, BP percentiles did not change with initiation of Burosumab therapy.Conclusion: Children with XLH demonstrate a high prevalence of hypertension as a third of our cohort met criteria for HTN. It is unclear why children with XLH develop HTN. FGF23 has been associated with vascular morbidity and elevated FGF23 drives the pathology in XLH. We did not see that anti-FGF23 treatment (Burosumab) lowered BP percentiles, but this could be confounded by a small sample size and the limited duration of follow up. HTN is an important comorbidity in XLH, and further studies are needed to identify risk factors.

microRNA Signature in Adult Patients with Hypophosphatasia *Roland Kocijan[1], Zora Messner[2], Benjamin Hadzimuratovic[3], Julia Feurstein[3], Jochen Zwerina[3], Andreas Diendorfer[4], Matthias Hackl[4], Heinrich Resch[2], Judith Haschka[5]. [1]Ludwig Boltzmann Institute of Osteology, . [2]St. Vincent Hospital Vienna, 2nd Medical Department, Vienna, Austria, Austria. [3]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of OEGK and AUVA Trauma Centre Meidling, 1st Medical Department Hanusch Hospital, Vienna, Austria, Austria. [4]TAmiRNA GmbH, Vienna, Austria, Austria. [5]Ludwig Boltzmann Institute for Osteology, Hanusch Hospital Vienna,

Background&Purpose Hypophosphatasia (HPP) is a rare genetic disorder, characterized by hypomineralization, recurrent fractures, musculoskeletal pain and extra-skeletal manifestations. The serological hallmark is low TNSALP (tissue non-specific alkaline phosphatase) activity and accumulation of natural substrates, such as PLP (Pyridoxalphosphate). Data on microRNAs (miRNAs) are lacking. Methods Circulating miRNAs, PLP and established bone turnover markers were analyzed in a cohort of adult HPP patients and healthy age- and sex-matched controls (CTRLs) in a cross-sectional design. Next-generation sequencing (NGS) of serum samples was performed and validation of selected miRNAs is ongoing using Reverse-transcriptase-quantitative PCR (RT-qPCR; TAmiRNA). Results Serum of 22 adult HPP patients and 23 CTRLs (47.9+/-14.2 vs.45.9+/-8.8 years, p=0.980) were analyzed. Alkaline phosphatase levels (ALPL) were significantly lower in HPP than

CTRLs (U/L;23+/-11 vs. 54+/-28, <0.0001). PLP-levels were above the reference range in 55% of patients (µg/L;36.3+/-98.2). 91% of patients reported musculoskeletal pain, 14 patients had history of fractures and 1 patient reported poor fracture healing. No patient had a history of seizures, diffuse neurological symptoms (e.g.headache) were reported of 41% of patients. In total, 84 miRNAs were differentially regulated in HPP vs. CTRLs (44 up- and 40 down-regulated, p-adj0.7, LOG FC 0.8/-0.8, p-adj.<0.05; e.g. miR-1-3p muscle, miR-107 brain, miR-26b-5p osteogenesis). Conclusion Adult HPP patients show a distinctive miRNA-signature compared to healthy population and an association to clinical manifestations. Differently regulated miRNAs display not only an affection of the musculoskeletal system including osteogenic differentiation/proliferation and muscle strength/dystrophy, but also display extra-skeletal manifestations in adult HPP.

SUN-492

A Phase 1, Open-label, Dose-escalating Study to Evaluate the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of ALXN1850 in Adults With Hypophosphatasia *KATHRYN DAHIR[1], Derek Dunn[2], Jawad Hasan[2], Amy Shannon[2], Wei-Jian Pan[2]. [1]Vanderbilt University Medical Center, [2]Alexion, AstraZeneca Rare Disease, United States

Hypophosphatasia (HPP) is a rare, inherited disorder associated with recurrent fractures/pseudofractures, orthopedic/dental burden, pain, mobility impairments, and diminished quality of life. ALXN1850 is an investigational enzyme replacement therapy being developed for the treatment of HPP.1-3 The primary objective of this study was to assess the safety and tolerability of ALXN1850 administered by IV weekly as 1 dose and SC for 3 weeks. Secondary objectives included pharmacokinetics (PK) of 1 IV and 3 SC doses, absolute bioavailability of SC, pharmacodynamic (PD) effects of 1 IV and 3 SC doses, and immunogenicity potential of ALXN1850. Of the 23 adult patients with HPP who signed informed consent, 15 were dosed, and each cohort of 5 received ALXN1850 (15, 45, or 90 mg) as 1 IV dose weekly and SC for 3 weeks; 3 patients missed doses due to COVID-19 but did not discontinue the study. Following IV and SC doses, peak and total exposure of ALXN1850 increased dose dependently (15-90 mg). Effective t1/2 was estimated at 3-6 days depending on dose. Mean bioavailability of SC doses was ~43% (range: 6%-75%). ALXN1850 achieved maximal lowering (nadir) of plasma inorganic pyrophosphate (PPi) in 7 days; ~40% post-dose PPi concentrations were below the limit of quantification (0.75µM). Mean PPi concentration was reduced for 3-4 weeks post-dose. There was no apparent impact of immunogenicity on ALXN1850 PK/PD. ALXN1850 has acceptable safety, tolerability, and PK profiles, demonstrating a sustained reduction in PPi concentrations in patients with HPP. These results will inform the selection of an appropriate therapeutic dose in future studies.References:1. Baumgartner-Sigl S et al. Bone. 2007;40(6):1655-1661.2. Whyte MP et al. Safety Overview Table

Safety finding, n (%)	Description (N = 15) of 4 weeks treatment with ALXN1850
Any TEAE	12 (80.0%); 46 events
Related TEAE	10 (66.7%); 29 events
Injection site reactions (ISRs)	8 (53.3%); 10 out of 41 (24.4%) SC injections led to an ISR event* • Four patients with 1 ISR (erythema) • One patient with 1 ISR (soreness, swelling, and redness) • One patient with 1 ISR (erythema and bruising) • One patient with 3 ISRs, 1 per each SC administration (erythema and pruritus; erythema and ecchymosis; erythema) • One patient with 1 ISR (bruise) Four patients had 1 ISR each of erythema, not reported as TEAEs but included in this ISR total. One patient experienced induration following the IV dose, which is not included in this ISR total
Injection associated reactions • **Systemic reactions**	1 (6.7%) Headache (grade 1), considered related to study drug,*** occurred following the start of the IV dose and resolved the same day following medical intervention.
TESAE	1 (6.7%) Atrial fibrillation (grade 3) considered not drug related***
TEAE/TESAE leading to study drug withdrawal	0
Immunogenicity (ADA+)**	4 (26.7%) Only 1 (6.7%) was treatment emergent; ADAs persisted to the end of the study. Per protocol, patient was offered follow-up via the HPP registry. No patients tested NAb+

*Most cases of erythema resolved in less than 2 hours following the SC dose. There was no pattern observed in the timing of SC administration (ie, first, second, or third dose) and the occurrence of erythema.
**Assays for measuring anti-ALXN1850 antibodies and neutralizing antibodies (NAbs) were fully validated for precision, specificity, selectivity, sensitivity, robustness, and drug tolerance following the current 2019 FDA guidance on ADA method validation.
***By the investigator.
ADA, antidrug antibody; AE, adverse event; HPP, hypophosphatasia; IV, intravenous; NAb, neutralizing antibody; SC, subcutaneous; TEAE, treatment-emergent adverse event; TESAE, treatment-emergent serious adverse event.

SUN-493

Utilization of EMR Filters to Identify Potential Cases of Occult Hypophosphatasia in a Single Health System *Camille Moeckel[1], Joshua Chen[1], Zara Karuman[1], Masayo Mesler[1], Edward Fox[1]. [1]Department of Orthopaedics and Rehabilitation, Penn State Milton S. Hershey Medical Center, United States

Occult hypophosphatasia (HPP) is a rare metabolic bone disorder caused by mutations in the ALPL gene; it is characterized by a wide variety of clinical symptoms including a persistently low tissue-non-specific alkaline phosphate (ALP). ALP is important for mineralization of the bones and teeth. Therefore, HPP can have serious consequences if left undiagnosed. Identifying patients with HPP can be challenging because a low ALP is uncommonly encountered in clinical practice and HPP has a nonspecific clinical presentation in milder forms. Electronic medical record (EMR) systems have become an integral part of patient care, and there is growing interest in their potential to improve disease surveillance and early diagnosis. The purpose of this study is to investigate the use of EMR filters in the identification of potential cases of occult HPP in a large, rural health system. After IRB approval, our Information Technology department utilized filters to identify adult patients (>18) who had visited the health system from 2014 to 2018 and had two consecutively low ALP levels (serum alkaline phosphatase <=30 IU/L). Patient charts that met the search criteria were then reviewed by the research team to confirm the potential diagnosis and collect data on their clinical characteristics. Exclusion criteria for patients included the presence of diseases and treatments known to decrease ALP levels, such as active cancer, multiple myeloma, overt hypothyroidism, malnutrition, pernicious or profound anemia, multiorgan/hepatic failure, bisphosphonate therapy, chronic glucocorticoids, and ongoing chemotherapy. Of the 733,860 unique patients seen between 2014 and 2018, 273 patients were identified with two consecutively low ALP levels. Among these patients, 28 were identified after chart review as potentially having occult HPP. Common symptoms reported included musculoskeletal pain, recurrent fractures, myalgia, chondrocalcinosis, and dental problems, such as periodontal disease. In conclusion, the utilization of EMR filters to identify potential cases of occult HPP has shown to be an effective approach; by leveraging the power of EMRs, healthcare providers can quickly identify patients at risk for HPP and initiate appropriate interventions. Going forward, the next step would be to contact the identified patients for further evaluation and management. By taking a proactive automated approach to screening and diagnosis, outcomes can potentially be improved for patients with HPP.

Prevalence of ENPP1 variants among patients with ossification of the posterior longitudinal ligament *Hajime Kato[1], Shivani Srivastava[2], Paul Stabach[3], Soichiro Kimura[4], Takashi Sunouchi[4], Yoshitomo Hoshino[4], Naoko Hidaka[4], Minae Koga[4], DEMETRIOS BRADDOCK[5], Nobuaki Ito[6,1], [2]Department of Pathology, Yale University, United States. [3]Department of Pathology, Yale Universty, United States. [4]Division of Nephrology and Endocrinology, The University of Tokyo Hospital, Japan. [5]YALE UNIVERSITY, United States. [6]The University of Tokyo Hospital, Japan

Background: Ossification of the posterior longitudinal ligament (OPLL) is a multifactorial disease that is caused by genetic and environmental factors. On the other hand, some hereditary FGF23-related hypophosphatemic rickets/osteomalacia (heterozygous PHEX mutation, homozygous ENPP1 mutation, homozygous DMP1 mutation) are known to develop OPLL. We, therefore, hypothesized that mild or undiagnosed cases of these diseases are included in the patients diagnosed with OPLL.Methods: We prospectively evaluated the frequency of cases with low-frequency variants (allele frequency in gnomAD: <0.5%) in the exonic regions of PHEX, ENPP1, and DMP1 genes in patients who underwent surgery for OPLL at our hospital. Clinical and biochemical data (i.e. calcium, phosphate, FGF23) of were collected. Plasma inorganic pyrophosphate (PPi) levels, which ENPP1 produces by hydrolyzing ATP, were also measured to evaluate the effect of the detected variants on ENPP1 catalytic activity.Results: The total of 50 patients with OPLL were included in this study (median age, 68 years [range, 37-86 years]; 14 women [28%]). All OPLL patients underwent genetic testing, and four types of heterozygous rare ENPP1 variants (c.802T>C [p.Y268H], c.1352A>C [p.Y451C], c.2089G>A [p.V697M], c.2335A>C [p.T779P]) were found in seven patients (14%). Clinical and biochemical data analysis showed that FGF23 levels of the OPLL patients with ENPP1 variants (median: 46 pg/mL [range: 36-102 pg/mL]) were higher than those of OPLL patients without ENPP1 variants (median: 36 pg/mL [range: 14-86 pg/mL]) (p=0.01). All of seven OPLL patients with heterozygous ENPP1 variants presented low plasma PPi levels (median: 1.8µM [range: 1.0-1.9 ?M], reference value 2-5 ?M). In vitro kinetic assays showed p.Y268H, p.Y451C, p.V697M and p.T779P variants possessed a catalytic velocity of 5%, 30%, 30%, and 1%, respectively, compared with that of wild-type ENPP1.Conclusion: This study revealed that patients with heterozygous ENPP1 variants were included in patients with OPLL and the prevalence of ENPP1 variant in this cohort was 14%. The establishment of the appropriate diagnostic criteria to select cases with pathogenic ENPP1 variants would be warranted.

BackgroundXLH is a rare, genetic, life-long disease caused by PHEX pathogenic variants. It is associated with progressive accumulation of musculoskeletal features and symptoms that evolve across the patient's lifetime if untreated. Although the disease is well characterised in children and adults, there are limited data describing the health outcomes and experiences of adolescents, particularly at end of skeletal growth (EOSG), a crucial phase during transition to adulthood.To explore these unmet needs, a collaborative, patient-centric, mixed-methods protocol was developed to assess functionality and health-related QoL (HRQoL) in adolescents with XLH at EOSG, including caregiver perspectives.MethodsMy XLH (NCT05181839) is a 12-month, multicentre, non-interventional, observational, prospective study using a mixed-methods approach. Research questions and methodology were designed collaboratively by patient-centred outcome research specialists, adolescents with XLH, caregivers, expert European physicians, and specialist technology providers.Descriptive analyses of quantitative and qualitative data will assess the experiences of adolescents and caregivers in the pre-index (before EOSG) and post-index (after EOSG) periods. Targets of 30 adolescents and 15 caregivers were considered sufficient to reflect diversity of opinions and experiences.The study setting is specialist centres in Europe that treat adolescents with XLH with burosumab.The target population is adolescents aged 12-17 years with genetically confirmed XLH treated with burosumab for >=12 months and confirmed as approaching EOSG. Patients non-adherent to treatment, or scheduled for orthopaedic surgery during the study will be excluded.Data will be collected for 4 weeks before and 26 weeks after EOSG. Analyses will be conducted to describe characteristics, symptoms, activities, and experiences of adolescents during treatment pre- and post-EOSG (with comparisons over time between patients continuing and discontinuing treatment post-index). Caregivers will be interviewed about their experiences and support needs of adolescents.ResultsRecruitment began on 24 November 2021. As of 18 April 2023, 24 patients have been enrolled. Enrolment is due to be completed by end of December 2023. Data analysis is planned to commence in 2024. ConclusionOur multistakeholder, mixed-methods research design in a rare disease offers an inclusive approach to better understand patient and caregiver experience.

[6]Université Paris Cité and APHP, France. [7]Johns Hopkins University, United States. [8]Yale University School of Medicine, United States

Background: Over the past 5 years, there have been rapid advances in our understanding of the multisystem manifestations of XLH and the development of new treatment paradigms. To offer guidance to clinicians and to promote evidence-based care, an International Working Group (IWG) of 52 experts in guideline development methodology and XLH in the pediatric and adult population has convened to develop new evidence-based guidelines on the evaluation, management, and monitoring of XLH.Methods: Four systematic reviews and meta-analyses were completed using the GRADE methodology addressing the management of XLH in relation to patient important outcomes and surrogate outcomes. In addition to the systematic reviews, expert clinical practices were captured with a comprehensive, 280 item questionnaire developed by the panel and administered to 44 experts treating patients with XLH. Data derived from the questionnaire were captured in expert-opinion based narrative reviews that address: 1) diagnosis of XLH including the role of genetic testing, 2) dental complications, 3) indications for treatment, 3) selection of treatment, 4) disease and treatment monitoring, 5) pregnancy and lactation in XLH, 5) agenda for future research.The new international guidelines on XLH will be reviewed by stakeholders including professional medical societies and patient advocacy organizations interested in endorsing these guidelines.Conclusions: These new guidelines will be presented for the first time internationally at the upcoming meeting of the ASBMR in October 2023.International Working Group Members:Aliya A. Khan (Chair), Dalal S. Ali, Maria L. Brandi, Eric Rush, Hajar Abualarob, Hatim Alalwani, Abdulrahman Alamri, Rana Aldabbagh, R.Todd Alexander, Farah Alsarraf, Natasha Appelman-Dijkstra, Signe Sparre Beck-Nielsen, Martin Biosse Duplan,Tom Carpenter, Catherine Chaussain, Martine Cohen-Solal, Rachel K. Investigating PTH-Independent CaSR Inhibition on Renal Calcium handling: Rationale and Design for a Phase 2 Clinical Trial (NCT05735015) *Iris Hartley[2], Rachel Gafni[2], Kelly Roszko[2], Karen Pozo[2], Kimberly Ampuero[2], Ananth Sridhar[3], Arun Mathew[3], Mary Scott Roberts[3], Scott Adler[3], Edward Nemeth[4], Michael Collins[2]. [2]National Institutes of Health, United States. [2]National Institutes of Health, , [3]Calcilytix Therapeutics, Inc., United States. [4]MetisMedica, Canada

Parathyroid hormone (PTH) and the Calcium-sensing receptor (CaSR) are the primary regulators of blood and urinary calcium levels. The relative and/or hierarchical contributions of PTH and the CaSR in regulating renal calcium handling, an important physiologic focus of their action, are not well understood, largely due to their intertwined physiology. CaSR activation and inhibition directly impact PTH secretion, thus confounding the ability to isolate their independent effects on calcium regulation. We propose that studying patients with absent or insufficient circulating PTH, as is seen in postsurgical hypoparathyroidism (PSH), with the oral negative allosteric CaSR modulator encaleret will reveal PTH-independent CaSR effects on calcium handling. We further hypothesize that encaleret will sufficiently lower urine calcium and increase blood calcium levels to serve as a primary or adjuvant oral treatment option for patients with PSH. To test these hypotheses, we have designed an open-label, phase 2, proof-of-principle study using encaleret to evaluate PTH-independent effects of CaSR modulation on renal calcium handling in PSH. The study will enroll up to 10 patients with PSH >1 year since surgery (permanent PSH) and up to 5 patients with PSH <1 year since surgery. Calcitriol will be discontinued, calcium supplementation continued and adjusted, and encaleret 162 mg administered every 12 hours for 5 inpatient days. Patients will undergo serial sampling of markers of mineral metabolism and 24-hour urine assessments. This dose, the highest studied to date, was selected to avoid missing a drug effect due to inadequate dosing. Participants with <1 year of PSH will be studied to assess the ability of high dose encaleret to identify PTH reserve in early PSH. The primary and secondary endpoints are: 1) change in fractional excretion of calcium and 2) the proportion of patients who achieve a concomitant normal fasting albumin-corrected blood calcium level and normal 24-hour urinary calcium excretion. Exploratory endpoints include pharmacokinetics, changes in albumin-corrected and ionized blood calcium, intact PTH, cyclic AMP excretion, 1,25-(OH)2 Vitamin D, C-telopeptide, procollagen type 1 N-propeptide, and urinary supersaturation analyses. We anticipate that the results will inform our understanding of renal mineral physiology and clarify the potential of encaleret as a treatment option for patients with PSH.

Age at diagnosis of XLH amongst children with and without a family history: Findings from the International XLH Registry *Suma Uday[1], Kerry Sandilands[2], Angela Williams[2], M. Zulf Mughal[3]. [1]Birmingham Women's and Children's Hospital & Institute of Metabolism and Systems Research, University of Birmingham, United Kingdom. [2]Kyowa Kirin International, United Kingdom. [3]Department of Paediatric Endocrinology & Metabolic Bone Disease, Royal Manchester Children's Hospital & The Faculty of Biology, Medicine & Health, University of Manchester, United Kingdom

Background: X-linked hypophosphatemia (XLH) is a rare, progressive, genetic phosphate wasting disorder leading to rickets, lower limb deformities as well as short and disproportionate stature. The condition is inherited in the majority, however spontaneous mutations are reported in ?30% of cases. Its rarity, coupled with its diverse clinical manifestations, may lead to delayed diagnosis and subsequently delayed treatment initiation. The objective of this analysis is to investigate if there is a delay in diagnosis for children without a family history (FH) compared to those with a FH.Methods: The International XLH Registry (NCT03193476) is a multicentre, prospective, non-interventional study initiated in 2017, aiming to recruit 1,200 people with XLH, collecting data prospectively for a period of 10 years. All participants of all ages with a confirmed diagnosis of XLH, regardless of their treatment and management, are included in the Registry.Results: At the database lock for the first analysis (29 March 2021), 579 participants had entered the registry before 30 November 2020, of which 360 were children. Date of diagnosis and data for FH were available for 195 of the 360 children. Of 195 children, 121 (62%) reported FH of XLH, defined as having a biological parent(s) affected, whereas 74 (38%) had no FH of XLH. Of those with a FH, the biological mother was affected in 77%, biological father affected in 22%, and both affected in 1% of cases. Children aged <18 years with no FH were significantly older at time of diagnosis (3.96 years) compared to those with a FH (1.47 years), p<0.001. Males (n=74) and females (n=121) did not differ in terms of age at diagnosis.Conclusions: All XLH patients without a FH of XLH were diagnosed significantly later than patients with a FH. Younger patients with a FH appear to be diagnosed more quickly than older patients, suggesting increased disease awareness.

Age Group Years	FAMILY HISTORY OF XLH		NO FAMILY HISTORY OF XLH		P-value
	n	Age at XLH Diagnosis (years), Mean (SE)	n	Age at XLH Diagnosis (years), Mean (SE)	
<5	28	0.43 (0.06)	4	0.97 (0.15)	p=0.07
5 < 12*	58	1.43 (0.25)	38	4.31 (0.34)	p<0.001

Efficacy of growth hormone therapy on height in children with achondroplasia *Takuo Kubota[1], Hirofumi Nakayama[2], Takeshi Ishimi[3], Chieko Yamada[3], Yukako Nakano[3], Ikumi Ueda[3], Tatsuya Nakamichi[3], Hiroyuki Saitou[3], Kenichi Yamamoto[4], Makoto Fujiwara[6], Yasuhisa Ohata[6], Taichi Kitaoka[1], Keiichi Ozono[1]. [1]Osaka University Graduate School of Medicine, Japan. [2]Department of Pediatrics, Graduate School of Medicine, The first Department of Oral and Maxillofacial Surgery, Graduate School of Dentistry, Osaka University , Japan. [3]Department of Pediatrics, Osaka University Graduate School of Medicine, Japan. [4]Department of Pediatrics, Division of Health Sciences, Osaka University Graduate School of Medicine, Japan. [6]Osaka University, . [6]Osaka University, Japan

Background: Achondroplasia (ACH) is a skeletal disorder with marked short stature and short limbs. The mean adult height has been reported to be 130.4 cm in males and 124.0 cm in females, respectively, in Japan, resulting in difficulties of daily life. Growth hormone (GH) therapy is available in children with ACH in Japan, although evidence on the efficacy of GH therapy on height growth is limited. Aim: To elucidate the efficacy of GH therapy on height growth in children with ACH. Methods: Children with ACH who visited our department from January 2011 to December 2022 and received GH therapy were included in this study. Height data between a year before and 5 years after the initiation of GH therapy were collected annually. Height SD values for healthy and ACH children and annual growth velocity (AGV) were evaluated. No further data were included after discontinuation of the therapy. A height increase due to lower limb lengthening was subtracted from the height measured. Results: Forty?one children (25 males) with ACH were included in the study. The median age was 4.00 years (range: 3.04 to 8.50) at the beginning of GH therapy. Height SD at that time was ?4.95 +/- 0.75 (mean +/- SD) for healthy children and ?0.24 +/- 0.71 for children with ACH. AGV was 4.45 +/- 1.62 cm. Regarding the efficacy of the therapy, the mean height SD of ?4.28, ?4.01, ?3.69, ?3.83, and ?3.84 for healthy children significantly increased 1 to 5 years after GH therapy, respectively, compared to that at the therapy initiation. In addition, the mean height SD of 0.25, 0.51, 0.95, 1.03 and 1.18 for children with ACH significantly increased in 1 to 5 years after GH therapy, respectively. AGV was 7.40, 5.76, 5.66, 4.84 and 4.77 cm 1 to 5 years after GH therapy, respectively, and significantly higher 1 to 3 years after GH therapy compared to that at the therapy initiation. Four and one patients underwent adenotonsillectomy and lower limb lengthening, respectively, after GH therapy initiation. GH therapy in 3 patients was changed to C-type natriuretic peptide analogue treatment. Except for the medical treatment change, no discontinuation of GH therapy occurred. Discussion: Height SD for both healthy and ACH children, and annual growth velocity were improved at least 1 to 3 years during GH therapy in this study, which shows the efficacy of GH therapy on height in children with ACH. Adult height needs to be evaluated in many patients with ACH after GH therapy.

SUN-503

Pharmacokinetics and Pharmacodynamics of Garetosmab in Patients with Fibrodysplasia Ossificans Progressiva *Yuhuan Wang[1], Jenny-Hoa Nguyen[1], Ruben De Ruiter[2], Jeanne Mendell[1], Dushyanth Srinivasan[1], John Davis[1], Elisabeth Eekhoff[3]. [1]Regeneron Pharmaceuticals, Inc., United States. [2], Netherlands. [3]Amsterdam UMC, location VU University Medical Center, Amsterdam, The Netherlands, Netherlands

Purpose: Fibrodysplasia ossificans progressiva (FOP) is a rare disorder caused by mutations in the bone-morphogenetic protein (BMP) type-1 activin-A receptor, characterized by episodes of soft tissue swellings, flare-ups, and progressive heterotopic ossification (HO) in skeletal muscles throughout the body. Garetosmab is an investigational fully human monoclonal antibody against activin-A that prevents formation of new HO. We report pharmacokinetic (PK) and immunogenicity data of garetosmab from the LUMINA-1 study.Methods: LUMINA-1 (NCT03188666) was a phase 2, randomized, double-blind, placebo-controlled study evaluating the safety and efficacy of garetosmab (10 mg/kg every 4 weeks intravenous) in adults with FOP over 28 weeks, followed by a 28-week open-label treatment period and a subsequent open-label extension. The PK, immunogenicity, concentrations of BMP9, and comparative exposure-response (E-R) analyses for efficacy and safety were performed with trough concentrations of functional garetosmab in serum (Ctrough) as exposure variables. Results: PK data were analyzed in 44 patients who received garetosmab. Plots of Ctrough over time showed that steady-state PK was reached 12-16 weeks after the first dose of garetosmab. After reaching steady state, Ctrough averaged (SD) 105 (30.8) mg/L. There was no meaningful difference in the PK profiles between patients who did and did not experience epistaxis. Immunogenicity assessments showed anti-garetosmab antibody formation with a persistently low titer in one patient (1/43; 2.3%), with no apparent impact on garetosmab PK or clinical effects. Median concentrations of BMP9 were approximately 40 pg/mL at baseline. Levels did not show treatment-related changes over time nor were differences seen between patients who did and did not experience epistaxis. The comparative E-R analyses demonstrated no association between Ctrough and efficacy (number of new HO lesions versus baseline) or safety (incidence or severity of treatment emergent adverse events of special interest, eg epistaxis or death).Conclusions: PK steady state was reached within ~12 weeks of starting garetosmab and no association was observed between higher serum exposures to functional garetosmab and the likelihood of experiencing adverse events. Incidence of anti-garetosmab antibodies was low and concentrations of BMP9 in serum had no apparent association with epistaxis. Garetosmab is being further evaluated in the phase 3 OPTIMA trial (NCT05394116).

A Phase 1/2, Open-Label, Multiple Ascending Dose Clinical Study to Evaluate the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of INZ-701 in Adults with ENPP1 Deficiency *Yves Sabbagh[1], Robert Wermers[2], Rainard Fuhr[3], Dirk Schnabel[4], Terra Arnason[5], Alix Besancon[6], Borut Cizman[1], Deborah Wenkert[7], Kurt Gunter[1]. [1]Inozyme Pharma, United States. [2]Mayo Clinic, United States. [3]Parexel International GmbH, Early Phase Clinical Unit Berlin, Germany. [4]Charitè, Universitätsmedizin Center for Chronic Sick Children, Pediatric Endocrinology, Germany. [5]University of Saskatchewan, Division of Endocrinology, Canada. [6]Hôpital Universitaire Necker Enfants Malades, Endocrino-diabetologie pediatrique , France. [7]Wenkert and Young, LLC, United States

Background: ENPP1 Deficiency is a rare disorder due to inactivating mutations in the ENPP1 gene. It is characterized by low levels of inorganic pyrophosphate (PPi), a critical regulator of mineralization; subsequent pathologic soft tissue calcification results in ~50% infant mortality and life-long musculoskeletal and cardiovascular morbidities. No targeted therapy exists for this disease. INZ-701 is a recombinant ENPP1-Fc investigational product which has demonstrated efficacy in preclinical models of ENPP1 Deficiency.Purpose: To determine the safety, tolerability, immunogenicity, pharmacokinetics and pharmacodynamics of INZ-701 following subcutaneous administration in adults with ENPP1 Deficiency. Methods: Phase 1/2, multicenter, open-label, multiple ascending dose study including three cohorts of three adults each, with genetic confirmation and PPi <1300 nM (NCT04686175). Participants were dosed at Day 1, then twice weekly from Day 8 to the end of the study.

Results: In all 3 dosing cohorts as of January 10, 2023, INZ-701 was well-tolerated with no related serious or severe adverse events. Low titers of non-neutralizing anti-drug antibodies (<160) were observed in 7/9 patients. Rapid increase in mean PPi from baseline of 426+/-407 nM of was noted in all patients, reaching the healthy volunteer range within 6 hours of the first dose. Mean PPi across the 0.2, 0.6, and 1.8 mg/kg dosing groups from day 32 through last data cut was 1299+/-490 nM, 1472+/-516 nM, and 1462+/-233 nM, respectively. Six of eight evaluable participants showed improvements in overall health on the Global Impression of Change (GIC) scale, as reported by both participants and clinicians. Long half-life of approximately 126 hours and drug accumulation as shown by a greater than dose proportional exposure suggests the potential for once weekly dosing. All participants enrolled in the phase 2 portion of the study.Conclusions: INZ-701 demonstrated a rapid and sustained increase in PPi levels in all participants, was well tolerated, and exhibited a favorable safety profile with a potential for once weekly dosing. Improvements in GIC score were observed in 6/8 patients and this ongoing study will elucidate the impact of INZ-701 on additional clinical and functional endpoints.

Medical care use among patients with monogenic osteoporosis due to rare variants in LRP5, PLS3, or WNT1 *Sara Verdonk[1], Silvia Storoni[1], Lidiia Zhytnik[2], Wenchao Zhong[2], Gerard Pals[3], Barend van Royen[4], Mariet Elting[3], Alessandra Maugeri[3], Elisabeth Eekhoff[5], Dimitra Micha[6]. [1]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Internal Medicine Section Endocrinology, Rare Bone Disease Center Amsterdam, Amsterdam Movement Sciences, Netherlands. [2]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Human Genetics, Rare Bone Disease Center Amsterdam, Amsterdam Movement Sciences, Netherlands. [3]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Human Genetics, Netherlands. [4]Amsterdam UMC location University of Amsterdam and location Vrije Universiteit Amsterdam, Department of Orthopedic Surgery and Sports Medicine, Netherlands. [5]Amsterdam UMC, location VU University Medical Center, Amsterdam, The Netherlands, Netherlands. [6]Amsterdam UMC locateon Vrije Universiteit Amsterdam, Department of Human Genetics, Rare Bone Disease Center Amsterdam, Amsterdam Movement Sciences, Netherlands

PurposePathogenic variants in the LRP5, PLS3, or WNT1 genes can significantly affect bone mineral density, causing monogenic osteoporosis. Much remains to be discovered about the phenotype and medical care needs of these patients. The purpose of this study was to examine the use of medical care among Dutch individuals identified between 2014 and 2021 with a pathogenic or suspicious rare variant in LRP5, PLS3, or WNT1. In addition, the aim was to compare their medical care utilization to both the overall Dutch population and the Dutch Osteogenesis Imperfecta (OI) population.MethodsThe Amsterdam UMC Genome Database was used to match 93 patients with the Statistics Netherlands (CBS) cohort. Patients were categorized based on their harbored variants: LRP5, PLS3, or WNT1. Hospital admissions, outpatient visits, medication data, and diagnosis treatment combinations (DTCs) were compared between the variant groups and, when possible, to the total population and OI population.ResultsCompared to the total population, patients with an LRP5, PLS3, or WNT1 variant had 1.61 times more hospital admissions, 2.0 times more opened DTCs, and a greater proportion using medication. Compared to OI patients, they had 0.61 times fewer admissions.ConclusionDutch patients with an LRP5, PLS3, or WNT1 variant appear to require on average more medical care than the total population. As expected, they made higher use of care at the surgical and orthopedic departments. Additionally, they used more care at the audiological centers and the otorhinolaryngology (ENT) department, suggesting a higher risk of hearing-related problems.

Table 1. Admission incidence rate comparing the number of hospitalizations of Dutch patients with a pathogenic or a rare suspicious variant in *LRP5*, *PLS3* or *WNT1* to the total population between 2013 and 2019.

Mean yearly admission incidence rate on average per person	0-24 y	24-44 y	45-64 y	≥65 y	Total
LRP5, *PLS3*, or *WNT1* cohort	0.48	0.13	0.31	0.53	0.31
Total Dutch population	0.10	0.12	0.20	0.44	0.20
Incidence rate ratios:	4.69	1.04	1.58	1.22	1.61

Admissions include both day-case and inpatient admissions.

Development of an 18F-NaF PET/CT-Based Tool for Quantification and Characterization of Soft Tissue Calcification in Hyperphosphatemic Familial Tumoral Calcinosis (HFTC) *Aaron Sheppard[1], Faraz Farhadi[2], IRIS HARTLEY[3], Rachel Gafni[7], Michael Collins[5], Babak Saboury[6], Kelly Roszko[7]. [1]NIH, United States. [2]Geisel School of Medicine, Dartmouth, United States. [3]NIDCR/NIH, . [7]National Institutes of Health, United States. [5]NIDCR, NIH, United States. [6]Clinical Center, Department of Radiology and Imaging Sciences, NIH, United States. [7]National Institutes of Health,

Hyperphosphatemic familial tumoral calcinosis (HFTC) is a rare disorder which results from a deficiency of FGF23 signaling. Biochemical abnormalities include hyperphosphatemia and an elevated calcium x phosphate product, which likely drives the development of disabling soft tissue calcification. The study of HFTC and its response to treatment suffers from the lack of a quantitative technique to measure disease burden and activity. To address this, we developed 18F-NaF PET/CT and CT only imaging and analysis techniques to characterize and quantify calcifications in the NIH HFTC cohort. 11 patients with HFTC underwent either CT or 18F-NaF PET/CT imaging and the PET and CT voxel-level data were exported to and analyzed with MIM and MATLAB software. Analyses included CT-based bone data - volume and density (Hounsfield Units, HU), and PET-based mineral metabolic activity (Standardized Uptake Value, SUV).82% of patients had ectopic calcifications. The most frequently occurring and largest lesions were at the hips (n=9) and shoulders (n=5), 546.5 +/- 573.5 cm3 and 388.8 +/- 535.1 cm3 respectively. Large variations in total lesion volume and individual lesion volume over the cohort illustrated the great degree of heterogeneity in HFTC. Calcifications were also identified in the sclera of the eye, the colonic mucosa, the brain parenchyma and meninges/dura, and the para-vertebral region of the neck. In one patient who had four CT scans, we found that surgical intervention or repeated trauma increased the rate of growth of the lesions. Another patient had two 18F-NaF PET/CT scans, and voxel-by-voxel analysis found that the lesion increased in volume and density while decreasing in metabolic activity. These data demonstrate the utility of 18F-NaF PET/CT in identifying and quantifying the presence and mineral metabolic activity of calcific lesions and illustrate that CT and PET data provide complementary information that may inform the underlying pathomechanisms of calcification in HFTC. This technique will be useful in quantifying response to treatment in HFTC and likely applicable to other diseases of ectopic calcification.

Bronchial Obstruction in Osteogenesis Imperfecta can be detected by the Forced Oscillation Technique (FOT) *SILVIA STORONI[1], SARA VERDONK[2], Dimitra Micha[1], Patrick M.C. Jak[1], Marianna Bugiani[1], Elisabeth Eekhoff[3], Joost G. Van den Aardweg[1]. [1]Amsterdam UMC, Netherlands. [2]VUmc, Netherlands. [3]Amsterdam UMC, location VU University Medical Center, Amsterdam, The Netherlands, Netherlands

ABSTRACT Introduction Respiratory complications are a primary cause of death in individuals with Osteogenesis Imperfecta (OI), occurring three times more frequently than in the general population. However, current pulmonary function tests such as spirometry and body plethysmography are sometimes difficult to perform by OI patients, while reference values are not always applicable. The Forced Oscillation Technique (FOT) requires no effort from the patient and is a more patient-friendly method for detecting respiratory abnormalities. Objective This study investigates the potential value of FOT in the evaluation of respiratory function and the clinical management in OI patients. Methods Spirometry, body plethysmography and FOT (Modified Master Screen IOS) were performed in twelve OI patients, including two with OI type IV, two with OI type III, and eight with OI type I. Each patient underwent four FOT measurements, two before and two after the administration of salbutamol. Results FOT provided sufficient data to identify obstructive and possibly also restrictive pulmonary patterns. The resistance at 8 Hz decreased after administration of salbutamol, indicating that FOT is able to measure (sensitively) bronchial obstruction and its relief by therapy ($P < 0.05$). There appears to be a correlation between the relative change in forced expiratory volume in 1 second (FEV1) and the relative change in respiratory resistance at 8 Hz after salbutamol ($r^2=0.15$). Conclusions Bronchial obstruction can be detected by FOT in patients with OI during quiet breathing, making it an easily executable alternative to other lung function measurements. It also has the potential to provide information on expiratory flow limitation, restriction and reduced lung compliance.

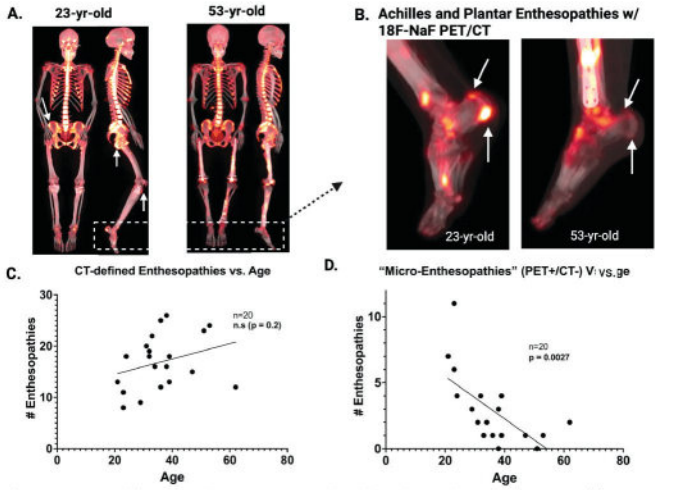
SUN-510

18F-NaF PET/CT is a Sensitive Tool for Detection of Prevalence and Activity of Enthesopathies in X-linked Hypophosphatemia *Aaron Sheppard[1], Babak Saboury[2], Juan Carlos Quintana[3], Oscar Contreras[3], Macarena Jimenez[4], Danisa Ivanovic-Zuvic[5], Annette Madison[5], Michael Collins[1], Pablo Florenzano[5]. [1]National Institutes of Health, National Institutes of Dental and Craniofacial Research, United States. [2]National Institutes of Health, Department of Radiology and Imaging Sciences, United States. [3]Pontificia Universidad Catolica de Chile, Radiology Department, Chile. [4]Pontificia Universidad Catolica de Chile, Endocrinology Department, Chile. [5]Pontificia Universidad Catolica de Chile, Endocrinology D, Chile

X-linked hypophosphatemia (XLH) is a rare metabolic bone disorder characterized by increased FGF23 production, which leads to chronic hypophosphatemia. Clinically, it presents with impaired skeletal mineralization and abnormal soft-tissue calcifications, including enthesopathies (Ens), leading to pain and diminished quality of life (QoL). To date, the natural history of Ens in XLH has been ill defined, due to the lack of a sensitive quantitative tool for its characterization and follow-up. Adult patients with genetically confirmed XLH were included. Clinical evaluations included severity surveys to assess QoL (SF23V), pain (BPI) and functionality (WOMAC/6MWT). 18F-NaF PET/CT scans, which can detect both the presence and metabolic activity of Ens, were acquired for all patient, and a comprehensive review of each patient's scan was performed. A subset of 14 common tendon/ligament insertion sites were chosen for further analysis, characterizing each site as CT-positive only (CT+) (macro-En) or PET-positive/CT-negative (PET+/CT-) (micro-En). Associations of macro- and micro-Ens with relevant clinical variables were performed, including linear regressions and Pearson's correlations. 20 patients were included, 70% women. Mean age at study was 35 years (21-62), with a mean age at diagnosis of 10 years (0.3-32). 18F-NaF PET was able to detect developing Ens in many locations before detection by CT (14.6% of all Ens). Notably, the number of PET+/CT- Ens was negatively correlated with age (r=-0.634, p=0.0027). The number of CT+ Ens had an insignificant positive correlation with age (r=+0.29, p=0.200). In addition, 18F-NaF PET offered synergistic information to CT, allowing the differentiation between metabolically active (PET+) vs stable (CT+/PET-) Ens. To illustrate, only 25% of macro-Ens at the ischial tuberosity were 18F-NaF avid, while 95.7% at the Achilles tendon were 18F-NaF avid. This, the first study to describe the use of 18F-NaF PET in characterizing Ens in XLH, demonstrated the ability of this modality to detect early En development at many sites. The fact that the number of detectable micro-Ens (PET+/CT-) was negatively correlated with age, suggests a progression pattern from a metabolically active early-lesion to a more structurally detectable, inactive lesion. 18F-NaF PET/CT is a promising tool that opens a window to better understand the natural history of the disease and may be used to assess the response of early Ens to therapeutic interventions.



[18]F-NaF PET/CT differentiates between active and stable enthesopathies (Ens) in XLH. *(A) maximum intensity projection (MIP) of [18]F-NaF PET scan overlayed on CT MIP for a 23-yr-old patient and a 53-yr-old. (B) A focused look at the heel of the same 23- and 53-yr-old patients. Increased [18]F-NaF PET signal is greatest at the Achilles and plantar ligament in the younger patient, illustrating how this modality may detect the actively forming Ens earlier in life. (C) The number of CT+ Ens was insignificantly positively correlated with age, whereas (D) the number of PET+/CT- Ens was negatively correlated with age*

SUN-512

3D-DXA reveals dramatic effects of burosumab on trabecular and cortical envelopes in symptomatic adults with X-linked Hypophosphatemia. *Rucha Patki[1], Karl Insogna[2], Thomas Carpenter[2], Keerti Murari[3], Stephen Parziale[4], Yanhong Deng[4], Ludovic Humbert[5], Mirella Lopez Picazo[5]. [1]Yale School of Medicine, United States. [2]Yale University School of Medicine, United States. [3]Optum Medical, Carmel/Brewster Campus, United States. [4]Yale School of Public Health, Yale Center for Analytical Sciences, United States. [5]3D-Shaper Medical, Spain

Burosumab heals fractures and improves osteomalacia in symptomatic adults with XLH but its effect on bone mineral density has not been well characterized. A study using quantitative backscattered electron imaging and FTIC of iliac crest bone biopsies, reported complex changes in cortical and trabecular bone mineralization following a year of burosumab treatment (doi: 10.1002/jbmr.4641).To quantify the effect of burosumab on trabecular and cortical bone density in the hip, a weight-bearing skeletal site prone to fracture in XLH, hip DXA scans and 3D-Shaper software (v2.12.1,3D-Shaper Medical, Spain) were used to analyze scans from 20 subjects who participated in the Phase 3 burosumab trial. DXA scans were obtained prior to and 6, 12 and 18-24 months after beginning treatment with 1mg/kg of drug every 4 weeks. The Month 6 BMD data were considered baseline for subjects receiving placebo for the first 6 months of the trial. Data were analyzed using a repeated-measures multivariate model that included age, gender, height, weight and time-point as covariates. Areal BMD at the total hip (TH) and femoral neck (FN) showed highly significant increases compared to baseline at every time point. For the TH, increases between 6 and 12 mo., 6 and 18-24 mo. and 12 and 18-24 mo. were highly significant. At the FN, increases between 6 and 12 mo. and 6 and 18-24 mo. were significant. The trabecular volumetric BMD (vBMD) at TH showed a progressive, highly significant and dramatic 13.6% increase over the study course. The trabecular vBMD at the FN also showed a significant 14.1% increase. At both skeletal sites, the interval increases from baseline in trabecular vBMD were also highly significant.Cortical surface BMD which incorporates cortical density and thickness, increased significantly between 6 and 12 mo. (p=0.03) and between 6 and 18-24 mo. (p= 0.01) for the FN. There was also a significant increase in the FN cross-sectional moment of inertia (CSMI), a predictor of strength, at 12 (p<0.05) and 24 (P<0.002) mo. compared to baseline (Figure1).We conclude that burosumab dramatically increases trabecular bone density in the TH and FN as well as the amount of FN cortical bone and increases FN CSMI. Since fractures in XLH often occur in cortically-enriched, weight-bearing lower extremity bones, including the FN, these changes may help explain the drug's efficacy in healing all fractures including FN and suggests that it may reduce the risk for future hip fractures.

[12]Ultragenyx Pharmaceutical Inc., United States. [13]Ultragenyx, United States. [14]Yale University School of Medicine, United States

Purpose: To provide an update from the XLH DMP, which is an ongoing, non-interventional, prospective study with a 10-year planned duration, that characterizes disease progression and long-term effectiveness and safety of burosumab and other treatments (NCT03651505).Methods: Children (peds; <18 years) and adults (>=18 years) at DMP enrollment (Month 0; M0) were grouped according to burosumab treatment: Group 1 (Gr1) began burosumab in a prior clinical trial and have the longest exposure among the study population; Group 2 (Gr2) began commercial burosumab prior to/during the DMP; Group 3 (Gr3) had no burosumab exposure, but most received conventional therapy (CT; eg, oral phosphate and active vitamin D). Results from patients (pts) who completed Year 3 (Y3) at data cutoff are reported.Results: As of February 2023, 347 peds and 461 adults were enrolled in the DMP; mean (SD) age at M0 was 9.0 (4.8) years and 39.0 (14.7) years, respectively. Mean duration of burosumab exposure was similar between peds (133.1 [65.5] weeks) and adults (135.0 [72.0] weeks). At Y3, mean serum alkaline phosphatase was lower in peds receiving burosumab vs CT (Gr1: 287.3 [151.6] U/L; Gr2: 277.0 [142.4] U/L; Gr3: 474.5 [170.2] U/L). Additionally, mean serum phosphate levels were higher in peds receiving burosumab vs CT (Fig 1A). Mean serum phosphate levels were also higher in Gr1 and Gr2 adults vs Gr 3 adults (Fig 1B). Rickets severity scores (RSS) in Gr1 peds remained low at Y3 (-0.1 change from M0) and improved in Gr2 peds (-0.7 change from M0); no Gr3 pts had completed RSS at Y3. At M0, 75 (16%) adults across all 3 groups reported an existing diagnosis of spinal stenosis (SS) or spinal cord (SC) compression, including 36 pts (37%) in Gr1, 28 pts (14%) in Gr2, and 11 pts (7%) in Gr3. The majority of pts who had a previous diagnosis of SS or SC compression did not report worsening of their condition and did not undergo a related surgery at Y3. Comparing M0 to Y3, 4 pts (2 each from Gr2 and Gr3) had renal ultrasound score increases of >=2 and 1 pt from Gr2 showed improvement with score decreases of >=2; no Gr1 pts had score increases >=2. Burosumab was not associated with declines in renal function (as assessed by eGFR), urinary protein/creatinine ratio, or any new safety concerns in peds or adults.Conclusions: Long-term exposure to burosumab for up to 3 years in the DMP was consistent with its previously reported benefits vs CT and positively affected markers of disease activity.

A Systematic Literature Review of the Impact and Measurement of Mobility Impairment in Rare Bone Diseases *Inês Alves[1], Gabor Barton[2], Edward Hsiao[3], Luca Sangiorgi[4], Jaymin Upadhyay[5], Ingunn Westerheim[6], Alexander Artyomenko[7], Kim Croskery[7]. [1]Associação Nacional de Displasias Ósseas (ANDO), Portugal. [2]Liverpool John Moores University, United Kingdom. [3]University of California San Francisco, United States. [4]IRCCS Istituto Ortopedico Rizzoli, Italy. [5]Harvard Medical School, United States. [6]Osteogenesis Imperfecta Federation Europe (OIFE), Belgium. [7]Ipsen, United Kingdom

Purpose: Rare bone diseases (RBDs) are a group of over 700 genetic disorders involving the skeletal system. While existing research characterizes the impact of mobility impairments in few specific RBDs, there is a lack of evidence on impacts on activities of daily living (ADLs) and quality of life (QoL) across RBDs. Furthermore, tools capable of measuring RBD-related mobility in real-world settings need to be identified. This systematic literature review aimed to investigate: 1) the impact of mobility impairment on ADLs and QoL in individuals with RBDs, and 2) the adequacy of tools for measuring mobility in RBDs. Methods: Searches of MEDLINE/Embase, Google, and conference proceedings were performed. Studies published between 2011-2022, in people with the 461 RBDs listed in the 2019 Nosology and Classification of Genetic Skeletal Disorders, were included. Non-English language studies, animal/cell studies, narrative reviews, and editorial letters were excluded. Risk of bias was minimized by two independent reviewers assessing each full-text article for inclusion. Data from included studies were extracted into a pre-specified extraction grid. Results: Of 4,587 studies identified, 113 met the inclusion criteria, in which only 39 different RBDs were investigated (population sizes: 1-959 individuals). Mobility impairments were described for 58 cohorts of individuals with RBDs; most common issues were with joint function and gait. In the cohorts of individuals identified under objective 1 (N=58), mobility impairment was associated with a negative impact on ADLs (n=47; most commonly walking [27/47; 57.4%]) and QoL (n=36; most related to pain [29/36; 80.6%]). Overall, 61 mobility tools were identified, including 34 functional assessments, 22 questionnaires, and 5 technologies/applications. Only 9 tools were evaluated as valid, reliable, or responsive in an RBD population, and therefore considered adequate (Table). Few digital tools were identified, with no assessment of their adequacy or use in a remote setting. Conclusion: Many tools used to measure mobility in RBDs were identified, reflecting a lack of consensus on the most appropriate tools. No adequate tools capable of capturing multiple factors impacting individuals' daily lives in a remote setting were identified. Development of adaptable tools, or exploring novel uses of existing tools, would facilitate data collection in the real world, better characterizing the impacts of mobility impairments across RBDs.

Table: Mobility tools deemed adequate for the assessment of mobility in RBDs

Mobility tool	RBDs assessed
Brief Pain Inventory Short Form (BPI-SF)	Hypophosphatasia (HPP) Morquio A syndrome **X-linked hypophosphatemia (XLH)**
Functional independence measure (FIM)	Achondroplasia **Mucopolysaccharidoses (MPS)**
FOP-Physical Function Questionnaire (FOP-PFQ)	**Fibrodysplasia ossificans progressiva (FOP)**
International Classification of Functioning, Disability and Health (ICF) self-report questionnaire	**Skeletal dysplasias**
Patient-Reported Mobility Assessment (PRMA)	**Fibrodysplasia ossificans progressiva (FOP)**
Patient Reported Outcome Measure Information System (PROMIS)	**Osteogenesis imperfecta (OI)** Proteus syndrome **X-linked hypophosphatemia (XLH)**
Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC)	Nail patella syndrome (NPS) **X-linked hypophosphatemia (XLH)**

Identification of progenitor cells that contribute to heterotopic ossification in normal and inflammatory environment *Qian Cong[1], Yingzi Yang[2]. [1]Harvard University, Harvard School of Dental Medicine, Armenia. [2]Harvard University, United States

Heterotopic ossification (HO) is a debilitating condition characterized by the pathologic formation of ectopic bone that occurs as a common complication after injury or as a manifestation of particular genetic disorders. The identity of progenitor cells that contribute to GNAS mutation induced heterotopic ossification relevant to progressive osseous hetero-

plasia (POH) is unknown, which limits the effective treatment or prevention of ectopic bone formation and expansion. Based on our single-cell RNA sequencing analysis from a well-established POH mouse model, we found that PDGF signaling was much increased in ectopic cell population. Utilizing an inducible lineage-tracing mouse (Gnasf/f; Pdgfr?-CreERT2; Rosa26LSL-TdTomato), we found that Pdgfr?+ progenitor cells were induced to become osteoblasts in POH. Moreover, local induction with Tamoxifen tibia subcutaneous injection cause dramatic HO compared to systemic Tamoxifen injection, suggesting that Pdgfr?+ cells is the major cell population in HO formation which will be promoted by an inflammatory microenvironment. Importantly, pharmacological inhibition of Pdgfr? abolished HO without affecting normal bone homeostasis, providing a previously unrecognized therapeutic rationale to prevent HO. Since we found that the ectopic bone invaded into deep muscular region 3 months post Ad-Cre injection in POH mouse models, we tested the hypothesis that the muscle satellite cells and committed muscle cells could also be reprogrammed to form ectopic bone. Consequently, Gnas mutant mature myotube cells cannot reprogram to ectopic bone. Skeletal muscle precursors and muscle satellite cells in vivo contributed minimally to heterotopic ossification, and this contribution was not increased by cardiotoxin injection, which induces muscle regeneration and mobilizes muscle stem cells. Taken together, Pdgfr?-expressing progenitor cells respond to an inflammatory trigger, differentiate into osteoblast, contribute to heterotopic bone formation and expansion in animal models of POH. The understanding of the cellular basis of heterotopic ossification aids in the development of targeted, cell-specific therapies for the treatment and prevention of heterotopic ossification.

Inhibition of ACVR1 with a Neutralizing Antibody Significantly Inhibits Recurrence of Trauma-induced Heterotopic Ossification Following Resection in a Burn and Tenotomy Mouse Model *Nanditha Das[1], Johanna Jimenez[1], Andrew Murphy[2], Aris Economides[1], Sarah Hatsell[1], Kalyan Nannuru[1]. [1]Regeneron Pharmaceuticals Inc, United States. [2]Regeneron Pharmceuticals Inc., United States

Heterotopic ossification (HO) can occur in an acquired form due to severe trauma, or in the rare genetic diseases such as Fibrodysplasia Ossificans Progressiva (FOP). Both forms of HO arise from the endochondral ossification process, resulting in ectopic bone formation in soft tissues, including muscles and tendons, hence the molecular mechanisms that drive these processes are postulated to be similar. FOP mutations in ACVR1 impart neofunction to the receptor by gaining responsiveness to Activin A, and inhibition of Activin A with a neutralizing antibody completely abrogates HO in mouse FOP models and human FOP patients. However, we have shown previously that blocking Activin A did not alter either the incidence or severity of trauma HO, suggesting that Activin A induced signaling does not drive HO development in trauma HO patients who have WT ACVR11. On the other hand, we and others2 have previously shown that inhibiting BMP signaling using an ALK3-Fc ligand trap or small molecule inhibitors can reduce ectopic bone formation in mouse models of trauma and burn-induced HO. We further showed that inhibiting BMP signaling by blocking ACVR1 prophylactically using an ACVR1 neutralizing antibody significantly reduced the formation and progression of trauma-induced HO in a burn/tenotomy mouse model.Trauma HO patients sometimes undergo resection surgery to remove HO, so establishing efficacy of ACVR1 blockade against recurrent HO following surgical resection is necessary. Hence, we tested whether our neutralizing ACVR1 antibody prevents HO recurrence post-resection. After inducing the models using the Achilles tenotomy and burn injury, mice were allowed to develop HO for 6 - 7 weeks, after which they underwent HO resection and ACVR1 antibody treatment at 25 mg/kg once weekly was initiated. The mice were treated for 12 weeks post-resection. We observed a significant inhibition in HO recurrence and its progression post-resection surgery in the ACVR1 antibody treated mice compared to isotype control treated group. These data, together with our previous data, suggest that ACVR1 signaling plays a major role in the development and recurrence of trauma-induced HO and blocking it offers an effective therapeutic option.References:1. Activin A does not drive post-traumatic heterotopic ossification, Bone. 138:115473, 20202. Strategic Targeting of Multiple BMP Receptors Prevents Trauma-Induced Heterotopic Ossification, Mol. Sexually Dimorphic Low Bone Mass in Down Syndrome Mice is Associated with Decreased Testis Weight but not Compromised Reproductive Hormone Levels *ALYSSA FALCK[1], KIRBY M. SHERMAN[2], Dana Gaddy[3], Sophia Schutmaat[1], Abigail Leon[1], Larry Suva[4]. [1]Texas A&M University, United States. [2]Texas A&M University , . [3]College of Veterinary Medicine, Texas A&M University, United States. [4]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States

Down syndrome (DS), the result of trisomy at human chromosome 21 (Ts21), manifests in a variety of clinical, behavioral, and physical abnormalities. People with Ts21 have low bone mass and increased fracture risk, associated with decreased bone formation. Interestingly, these skeletal complications are more prevalent in Ts21 men, despite low-normal hormone levels in the HPG axis including testosterone. We previously demonstrated low bone mass in male DS mice of both TS65 and DP16 strains is a result of low bone accrual, however the female TS65 bone phenotype is unknown. Given the well-established importance of sex steroids for normal bone accrual in both humans and mice, we hypothesized that the low bone accrual in Ts65 and DP16 DS mouse models might be associated with deficiencies across the reproductive axis. Therefore, 3-month-old male and female DP16 and Ts65 DS mice were assessed for whole body BMD by DEXA, tibial bone volume by microCT, and reproductive function by serum reproductive hormone levels and gonadal and accessory sex gland tissue wet weights. Whole body BMD measurements confirmed low bone mass in male Ts65 and DP16 mice; however, no bone phenotype was evident in TS65 DS females. Despite normal reproductive hormone levels, male DS mice had significantly decreased testis, but not seminal vesicle, weights compared to WT. Female DS Ts65 and DP16 mice did not show significant differences in ovarian or uterine weights compared to WT. These murine data are entirely consistent with previous human data demonstrating that testosterone, FSH and LH levels in Ts21 men are all in the low normal range, providing evidence that the hypothalamic-pituitary-gonadal axis is intact. Collectively, these data demonstrate for the first time that the low bone mass phenotype of male DS mice is independent of reproductive hormone levels and that female Ts65 DS do not have low bone mass at 3 months of age. Thus, the sexual dimorphism evident in the human Ts21 bone phenotype is replicated in DP16 and Ts65 DS mice. These data further validate the utility of multiple DS mouse lines to accurately reflect the human Ts21 phenotype and provide novel insight into the cellular and molecular mechanisms of low bone formation in DS. Importantly, it provides further evidence that low bone mass of Ts21 patients and DS mice is not simply the result of low sex steroid levels, as previously speculated in the field.

role of calcium related signalling in osteoblasts: what we learned From Osteogenesis Imperfecta *Roberta Besio[1], Barbara M Contento[1], Nadia Garibaldi[1], Marta Filibian[1], Stephan Sonntag[2], Doron Shmerling[3], Francesca Tonelli[1], Marco Biggiogera[1], Marisa Brini[4], Andrea Salmaso[4], Milena Jovanovic[5], Joan Marini[5], Antonio Rossi[1], Antonella Forlino[1]. [5]National Institute of Child Health and Human Development, United States

Osteogenesis imperfecta (OI) is a group of inherited brittle bone diseases associated to skeletal deformities and bone fragility and mainly due to defects in collagen type I. Both altered bone matrix and impaired osteoblast homeostasis have been described in OI. Even if the molecular basis of the disease has been deeply investigated, is still largely poorly defined. The characterization of the rarest recessive OI forms has been and will be extremely relevant to further elucidate the disease pathophysiology. Mutations in TMEM38B, encoding the TRIC-B potassium channel necessary for intracellular Ca2+ homeostasis, cause the autosomal recessive OI type XIV characterized by defects in osteoblast (OB) differentiation and activity. To understand the molecular mechanisms underlying OB impairment in OI type XIV, a Tmem38b osteoblast specific conditional knock-out mouse (Runx2Cre;Tmem38bfl/fl, cKO) was generated and used to investigate pathways relevant for OB differentiation. Among these, the SMAD pathway, acting downstream the TGF-? and the Ca2+-dependent CaMKII, was evaluated.At the cellular level, the Ca2+ imbalance caused delayed osteoblast differentiation and decreased collagen synthesis associated with reduced collagen incorporation in the extracellular matrix and poor mineralization. The osteoblast malfunction was proved to be associated to the impaired SMAD signalling detected in mutant mice, and validated in OI patient osteoblasts. The reduced SMAD phosphorylation and nuclear translocation were mainly caused by alteration in Ca2+ calmodulin kinase II (CaMKII)-mediated signalling and to a less extend by a lower TGF-? reservoir. Indeed, TGF-? treatment only partially rescued SMAD signalling, osteoblast differentiation and matrix mineralization, underlying the relevance of CaMKII-SMAD axes on osteoblast function. In conclusion, our study established the TRIC-B role in osteoblasts and strengthen the contribution of the CaMKII-SMAD signalling in bone.

Skeletal phenotype in mice with a homozygous truncating PTH1R mutation resembles skeletal abnormalities in Eiken Syndrome *Jakob Höppner[1], Thomas Gardella[2], Monica Reyes[3], PATRICK HANNA[4], Harald Jueppner[2], Ignacio Portales Castillo[4]. [1]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, United States. [2]Massachusetts General Hospital, United States. [3]Massachusetts General Hospital , United States. [4],

Eiken syndrome is an ultra-rare disease characterized by delayed bone ossification that is caused by homozygous mutations in the parathyroid hormone/parathyroid hormone-related protein receptor (PTH1R). One of these mutants, R485X-PTH1R, lacks most of the receptor C-terminal tail, and in vitro exhibits impaired interaction with ?-arrestins, which are necessary for normal PTH1R desensitization. In transfected HEK293 cells, R485X-PTH1R exhibits increased basal cAMP signaling as well as enhanced PTHrP-stimulated cAMP formation responses. To investigate how this PTH1R mutant impacts endochondral bone formation in-vivo, we used iGONAD (improved genome editing via oviductal nucleic acids

delivery) to generate R485X "humanized" hPTHR1 mice, which express the human PTH1R under the control of the endogenous mouse promoter. The resulting R485X-hPTHR1 knock-in mice were viable in both heterozygous and homozygous states and were analyzed at different ages along with age-matched controls. Homozygous R485X-PTH1R mice had short tails, but otherwise appeared normal. Heterozygous mice were indistinguishable from WT littermates. Whole mount skeletons of homozygous mice exhibited reduced mineralization of the long bones and carpals on postnatal days 1-6. Histology of H&E-stained tibial sections revealed expanded zones of proliferative and hypertrophic chondrocytes in the growth plate. Analysis of explant cultures of metatarsals obtained at postnatal day 1, 4 and 10 confirmed a major delay in mineralization of bones from homozygous mutant vs. WT mice. Beyond day 21, metatarsal mineralization and growth plate histology appeared similar in mutant and WT mice; however, the mutant tarsal bones and vertebrae appeared shorter and misshapen. Homozygous R485X mice exhibited normocalcemia but serum PTH levels tended to be elevated suggesting moderate PTH-resistance. These homozygous R485X-hPTH1R mutant mice thus recapitulate the main features of patients with Eiken Syndrome (delayed ossification). Further, the results support an important role for the PTH1R C-tail and its interaction with ?-arrestins which may have a previously unrecognized role in regulating PTH1R signaling during endochondral bone formation.

Genetic Modulation of Hedgehog Signaling Influences Exostoses Elongation, Orientation, and Proliferation in a Mouse Model of Hereditary Multiple Exostoses (HME) *Sarah Catheline[1], Christina Mundy[2], Maurizio Pacifici[3]. [1]University of Rochester, United States. [2]Children's Hospital of Philadelphia, United States. [3]The Children's Hospital of Philadelphia, United States

Hereditary Multiple Exostoses (HME) is a congenital pediatric disorder in which cartilaginous tumors called osteochondromas or exostoses develop perpendicular to growth plates of skeletal elements. Most HME patients have a mutation in?EXT1?or?EXT2 causing heparan sulfate (HS) deficiency. Normally, HS-rich proteoglycans (HSPGs) restrict growth factor availability, and the HS deficiency in HME growth plates could result in freely available growth factors, inducing exostosis formation. However, it is unknown why the exostoses grow orthogonally to the growth plate main axis. The Indian hedgehog (IHH)/PTHrP signaling axis is critical for growth plate zonal organization, and hedgehog proteins bind HSPGs. Thus, HS deficiency in HME could allow the proteins to escape the growth plate and trigger a neo IHH-PTHrP axis within perichondrium, causing orthogonal exostosis formation. To test this novel thesis, we used AggrecanCreERT2? mice to drive?Ext1?deletion in chondrocytes and perichondrium in 5 week-old mice. To ask whether hedgehog signaling is necessary and sufficient for exostosis formation, we combined this model with: (a) conditional deletion of hedgehog receptor?Smo?resulting in Hedgehog loss of function (LOF); or (b) conditional deletion of?Ptch1, a negative regulator of signaling, resulting in gain of function (GOF). Acan-Cre+/-ERT2; Ext1f/f;?Smof/f?mice displayed delayed exostosis formation 10 days after tamoxifen relative to Acan-Cre+/-ERT2; Ext1f/f?(Ext1 mutant) mice, significantly decreasing exostosis number and size 4 weeks post tamoxifen. In contrast,?Acan-Cre+/-ERT2; Ext1f/f; Ptch1f/+?mice showed greater number of exostoses at 10 days relative to Ext1?mutant mice, resulting in significantly longer, wider and more numerous exostoses by 4 weeks. Notably, Ext1 mutants showed enriched cell proliferation marked by Ki67 in perichondrium at the site of new exostoses, while LOF mice lacked proliferating perichondrial cells and GOF mice showed the greatest number of Ki67-positive cells, suggestive that hedgehog helps initiate perichondrial proliferation. ?-catenin expression throughout the exostoses, and Pthrp-LacZ specifically present at their leading edge, both increased in Ext1 mutant mice and were further increased in GOF mice, suggesting that crosstalk between these pathways is important in exostosis formation. Our current data implicate IHH/PTHrP signaling as a critical regulator of osteochondroma formation and orthogonal growth.

KMT9? maintains bone homeostasis via JAK1-STAT3-mediated osteogenesis *Shuang Jiang[1], Quan Yuan[1], Mingyue Lyu[1]. [1]Sichuan University, China

Maintenance of bone homeostasis depends on coordinated bone formation by osteoblasts and bone resorption by osteoclasts. Disruption in this tightly-regulated process results in skeletal disorders, such as osteoporosis or osteopetrosis. Autosomal recessive osteopetrosis (ARO) is a lethal genetic disease, characterized by increased bone mineral content and density. However, the mechanism underlying ARO is still unclear and the treatment strategy is limited. Lysine methyltransferase 9 (KMT9) is newly identified as a histone methyltransferase that writes the monomethylated mark on lysine 12 of histone H4. Here we raise the possibility that KMT9?-mediated JAK1-STAT3 signaling pathway is highly relevant in the onset of ARO.First, we generated a mouse model with Kmt9? specific knockout in mesenchymal stem cells by crossing Kmt9?fl/fl mice with Prx1-Cre mice. It was first noted that Kmt9?-knockout mice exhibited stunted growth of limbs, especially the femurs, compared to their littermates. To further identify the extent of the skeletal defects, we analyzed the femurs of Kmt9?-knockout mice using a micro-CT scanner. Notably, micro-CT analysis revealed that the femurs of Kmt9?-knockout mice were shorter, deformed, and exhibited increased cortical mineral density and cortical thickness. This finding was reproduced via histomorphometry, which showed massively increased amounts of trabecular bone and reduced bone marrow space in the mutant mice. Interestingly, we also observed an increase of growth plate thickness in the absence of KMT9?.Considering the mutant mice resemble the major symptoms of the human disease, we extracted information from public sequencing data in bone tissue of patients with autosomal dominant osteopetrosis. A significant enrichment of JAK-STAT signaling pathway in bone of patients was then noticed. To uncover the mechanism driving skeletal disorder in low-level KMT9? setting, we silenced KMT9? in mesenchymal stem cells using siRNA and traced the cellular responses. As expected, we found a surge of expression in JAK1-STAT3 pathway with KMT9? deficiency. We therefore proposed a possibility that the hyperactive bone formation in Kmt9?-knockout mice may directly or indirectly come from JAK1 and STAT3 actions.Taken together, these data demonstrates that KMT9? is vital for skeletal development and bone homeostasis through JAK1-STAT3-mediated osteogenesis and suggest it be a potential target for ARO diagnosis and management.

PDGFR?-STAT5 Signaling Hijacks Growth Hormone Pathway to Promote Skeletal Gigantism *Hae Ryong Kwon[1], Lorin Olson[1]. [1]Oklahoma Medical Research Foundation, United States

Autosomal dominant platelet-derived growth factor receptor beta (PDGFR?) gain-of-function mutations cause skeletal gigantism in mice and humans with the rare genetic disease Kosaki overgrowth syndrome. However, the cellular basis and molecular mechanisms of these disorders are still being discovered. We previously showed that mice with a gain-of-function PDGFR? D849V point mutation on a Stat1-deficient background develop skeletal overgrowth. Skeletal stem cells (SSCs) isolated from these mice exhibit increased colony formation, suggesting overactive stem and progenitor cells as a cellular origin of overgrowth. Single-cell RNA transcriptomics with SSCs-derived colonies revealed in-

creased expression and phosphorylation of signal transducer and activator of transcription 5 (STAT5) and overexpression of the STAT5 target gene, insulin-like growth factor 1 (IGF1). We hypothesized that PDGFR? causes skeletal overgrowth by activating local STAT5-IGF1 signaling in the skeletal lineage. To investigate the significance of STAT5 and IGF1 in the overgrowth phenotype, we conditionally deleted Stat5, Igf1, or IGF1 receptor Igf1r, from the axial skeleton of PDGFR?D849VStat1-/- mice. For conditional gene deletion, we utilized Prx1-Cre which targets mesenchymal cells in the early limb bud including bone, cartilage, muscle connective tissue and dermal fibroblasts, but not skeletal muscle. Longitudinal and appositional skeletal overgrowth of PDGFR?D849VStat1-/- mice was normalized by deletion of Stat5, Igf1, or Igf1r, suggesting the importance of STAT5 and IGF1 signaling. With lineage tracing and immunostaining, we found that PDGFR? is expressed around the growth plate, suggesting paracrine actions of IGF1 leading to enhanced growth. We propose that by directly phosphorylating STAT5 in Prx1-lineage skeletal cells, PDGFR?D849V hijacks the growth hormone (GH) signaling pathway to promote skeletal overgrowth. Our work establishes the cellular basis of skeletal growth disorders caused by PDGFR? mutations and gives new insight into a role of STAT5 in skeletal development and genetic disease.

Osteopathy in Gorham-Stout Disease Animal Model *ERNESTO SOLORZANO[1], Gabrielle Robinson[5], Hope Ball[5], Adam Sanchez[3], Alexander Powell[3], Michael Kelly[4], Fayez Safadi[5], [1], United States, [5]Northeast Ohio Medical University, , [3]NEOMED, United States, [4]Cleveland Clinic Foundation, United States, [5]Northeast Ohio Medical University, United States

Gorham-Stout Disease (GSD) is a rare condition associated with aggressive lymphatic invasion into bone leading to massive bone loss. To date, the mechanism of bone loss identified in GSD remains to be elucidated. Most recently, a lymphatic-specific KRAS somatic activating mutation was identified in GSD patients. A mouse model recapitulating this mutation in Prox1 expressing lymphatic cells showed detrimental lymphatic valve formation. To better understand the abnormal bone loss present in GSD patients, we generated a tamoxifen-induced lymphatic endothelial cell KRAS somatic activating mutation in mice and characterized the skeletal phenotype. These mutant animals exhibited decreased body weight compared to wild-type littermates. In addition, we observed extensive lymphatic fluid accumulation in the thoracic cavity in comparison to wild-type littermates. Soft tissue immunohistochemical analysis of LYVE-1 (lymphatic endothelial cell marker) revealed lymphatic vessel invasion into the kidneys. Subsequently, bone mineral density, content, and area were all found to be decreased in KRAS mutants compared to wild-type mice. These results were also observed in KRAS mutant spine, femur, and tibia compared to wild-type controls. In addition, a decrease in total fat and lean muscle mass was also observed. Further, we next assessed bone mRNA expression and found a decrease in Runx2 and Collagen type I in mutant mice. However, the expression of osteoclast-related markers (TRAP, DC-Stamp, and Cathepsin-K) was increased in mutants compared to wild-type animals. When assessing bone marrow-derived macrophages, we found a decrease in cell proliferation associated with decreased total osteoclast count in mutant compared to wild-type. Interestingly, TRAP activity per osteoclast was increased in mutant compared to wild-type. Our findings show how a lymphatic-specific KRAS mutation leads to a decrease in bone mass in vivo and induces cell-autonomous changes in osteoclast differentiation ex vivo. For this reason, we predict mutant lymphatic tissue actively secretes bone-regulating factors capable of modulating bone homeostasis. In conclusion, our studies are the first to describe abnormal bone phenotypes found in KRAS mutant mice. Future studies aimed to identify lymphatic secreted factors responsible for bone loss and changes in osteoclast homeostasis observed in the GSD mouse model.

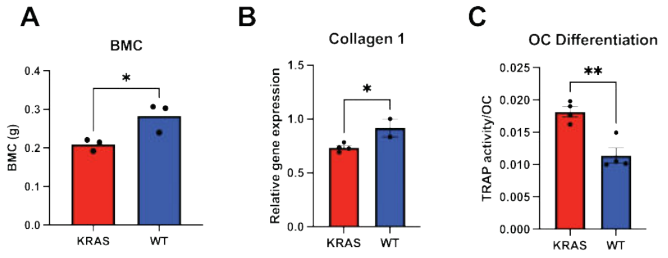

Figure 1. Osteopathic changes found in GSD animal model. Lymphatic specific KRAS activating mutation led to a decrease in bone mineral content (BMC) on mutant animals (KRAS) when compared to wild-type (WT) (**A**). Bone mRNA expression of collagen 1 was decreased in KRAS when compared to WT (**B**). Osteoclast (OC) TRAP activity per cell was higher in KRAS animals when compared to WT (**C**).

Unraveling Immune Alterations in the Pathogenesis of Pachydermoperiostosis through a Cross-Omic Analysis Informed by Heterotopic Ossification *jinsen lu[1], [1]Botnar Research Institute, United Kingdom

Pachydermoperiostosis (PDP) is a rare genetic osteo-related disorder with enigmatic etiology. Prior research has associated immune dysregulation with aberrant bone remodeling and cutaneous thickening. Building upon these findings, this study endeavors to examine immune alterations to further elucidate the pathophysiological processes of PDP.Comprehensive imaging and blood tests were performed on a PDP patient, his asymptomatic brother, and healthy controls. Single-cell sequencing of PBMCs revealed immune cell shifts in the PDP patient, including decreased NK cells, CD4 T helper cells, CD8 T cells, and increased B cells. A CTX-injured BMP4 transgenic mouse model was applied as PDP model to complement the human study. Lesion tissues were collected at different time points, and bulk RNA sequencing, histology, and micro-CT were conducted to trace tissue morphogenesis on mice models. Time-course clustering and WGCNA identified six functional clusters related to abnormal tissue morphogenesis in mice models. In the human study, top genes were mapped to identified murine clusters and validated via RT-PCR. NK cells displayed upregulated CPQ, COL6A2, and NSG1 (related to tissue morphogenesis) and altered immune response via upregulated THEMIS2 and downregulated AOAH. CD8 T cells showed upregulated CD300A and downregulated COTL1, influencing their activation and function, while downregulated SKAP2 and S100A9 affected their migration. CD4 T helper cells exhibited upregulated S100A4 and downregulated TMEM263, impacting their activation and communication, as well as altered chemotaxis due to downregulated MTURN and S100A8. B cells demonstrated upregulated CSTB and FCGR2B affecting their activation, migration, and antibody production, while downregulated S100A9, TLE4, HMGB2, PLPP5, and CXCR4 potentially contributed to PDP pathogenesis through regulating cell migration, cell cycle and inflammatory response.In conclusion, this study unveils novel insights into PDP pathogenesis, emphasizing the significance of immune cell population dynamics, altered gene expression, and mechanistic understanding, providing a foundation for future research and potential targeted therapies for PDP.

Distinct molecular mechanisms of bone and lung pathologies in a G610C Mouse Model of OI *ELENA MAKAREEVA[1], Megan Sousa[1], Muthulakshmi Sellamani[1], Edward L. Mertz[1], Satoru Otsuru[2], Sergey Leikin[3], [1]NIH, United States, [2]University of Maryland, United States, [3]National Institutes of Health, United States

Lung function in osteogenesis imperfecta (OI) is affected by both chest deformities and intrinsic lung tissue pathology. Alveolar disruption has been reported in mouse models and bronchial wall thickening in humans. The present study aims to provide mechanistic insights into the causes of the lung-intrinsic pathology in a G610C mouse model of moderate OI, which carries the same mutation in type I collagen alpha2(I) chain as in Old Order Amish patients. We previously demonstrated that bone pathology in G610C mice is largely caused by osteoblast and hypertrophic chondrocyte malfunction because of misfolded procollagen accumulation in the ER and consecutive cellular stress, specifically integrated stress response (ISR). Surprisingly, we found that lung pathology in G610C mice is more severe than bone pathology, homozygous (Hom) G610C neonates die at birth from lung failure caused by poorly developed saccular structures and massive parenchymal bleeding. In Hom E18.5 embryos, bone pathology was comparable to severely affected yet surviving Het animals while the lung pathology was more dramatic. In lung fibroblasts, unlike osteoblasts, we observed no ER disruption in electron microscopy (EM) and no ISR marker gene

upregulation in single cell (scRNASeq) or spatially resolved (srRNASeq) RNASeq. Instead, EM, histology, immunofluorescence, scRNASeq, srRNASeq, and in situ mRNA hybridization revealed deficient extracellular matrix (ECM) deposition, myofibroblast deficiency, and disorganization of lung epithelial cells, which filled the developing lung saccules instead of lining them. Altered gene expression by myofibroblasts and epithelial cells suggested abnormal cell interactions with the deficient ECM. In Het embryos, the lung pathology was less severe, but in 3- and 5-week-old Het mice we observed alveolar disruption, reduced alveolar surface/volume ratio, and increased respiratory frequency and volume/minute at rest (potentially compensating for the alveolar surface loss). In addition, many 3- and 5-week-old Het mice had lesions with inflammatory cell infiltration and various degrees of fibrosis, probably resulting from weak ECM being prone to injury. In 10-week-old Het mice, the alveolar disruption, lesions, and respiratory abnormalities were less pronounced, likely because of continuous lung remodeling in mice. These observations suggest that disruption of rapidly forming ECM and cell-ECM interactions by secreted mutant collagen molecules in embryos and young animals is the primary cause of the lung-intrinsic pathology in G610C mice, which is distinct from bone pathology.

Complex Abnormalities in Osteoblasts/Osteocytes of X-Linked Hypophosphatemia: Analysis of PHEX-Knockout Human iPS Cells Generated by CRISPR/Cas9 Genome Editing *Toshimi Michigami[1], Tatsuro Nakanishi[2], Miwa Yamazaki[2], Kanako Tachikawa[2], Ayu Ueta[2], Masanobu Kawai[2], Keiichi Ozono[3]. [1]Osaka Women's and Children's Hospital, Japan. [2]Osaka Women's and Children's Hospital, Japan. [3]Osaka University Graduate School of Medicine, Japan

X-linked hypophosphatemia (XLH) is caused by inactivating variants of the PHEX gene, which is highly expressed in mature osteoblasts and osteocytes. Although overproduction of FGF23 is responsible for hypophosphatemia and impaired vitamin D metabolism, pathogenesis of XLH is still not fully understood. Studies using Phex-deficient Hyp mice have suggested complex defects in osteoblasts and osteocytes: however, it is unclear whether the findings in Hyp mice are indeed shared by human XLH, partly due to the difficulty in obtaining sufficient numbers of osteoblasts/osteocytes from patients. Therefore, we herein generated PHEX-knockout (KO) human induced pluripotent stem (iPS) cells in order to use as a cell model for XLH. By applying CRISPR/Cas9-mediated gene ablation to an iPS clone derived from a healthy male, we obtained PHEX-KO iPS cells with a deletion extending from exon 1 to exon 3 and a frameshift. The parental iPS cells isogenic except for the PHEX gene were used as a control in the study. There was no obvious difference in cell viability/cytotoxicity between the PHEX-KO and isogenic control iPS cells. We then induced these iPS cells to differentiate into osteoblast-lineage by culturing in the presence of beta-glycerophosphate and ascorbic acid up to 49 days. The expression of PHEX was markedly increased by time in the isogenic control iPS cells, while the PHEX-KO cells completely lacked the functional PHEX transcripts. The expression of RUNX2, the master transcription factor of osteoblast differentiation, peaked on Day 28 in both the PHEX-KO and isogenic control iPS cells. We confirmed the increased production of FGF23 in the osteoblast-lineage cells differentiated from PHEX-KO iPS cells. Interestingly, in vitro mineralization was accelerated in the PHEX-KO iPS cells, which reminded us of ectopic calcification such as ossification of posterior longitudinal ligament (OPLL) often observed in adult patients with XLH. Extracellular levels of pyrophosphate, an inhibitor of mineralization, and adenosine triphosphate (ATP) in the conditioned media were elevated in the osteoblast-lineage cells derived from PHEX-KO iPS cells compared to those from isogenic control iPS cells, and this appeared to be associated with the reduced alkaline phosphatase activity. In addition, PHEX-KO iPS cells showed increased expression of multiple molecules such as DMP1, osteopontin, RUNX2, and FGF receptor 1, which was similar to the observations in the osteoblasts/osteocytes of Hyp mice. The expression of EGR1, a target of FGFR signaling, was also increased in the PHEX-KO iPS cells, suggesting an enhanced activation of FGFR signaling. The expression of KLOTHO was very low in the osteoblast-lineage cells from both iPS cells. Taken together, these results suggest that complex intrinsic abnormalities of osteoblasts/osteocytes may underlie the pathogenesis of XLH.

SP7/Osterix Neomorphic Mutation S309W-Zebrafish Model Recapitulates Human High Bone Turnover Disease *Diane Sepich[1], Gary S. Gottesman[4], William H. McAlister[3], Michael P. Whyte[4], Lilianna Solnica-Krezel[1], Steven Mumm[4]. [1]Department of Developmental Biology, Washington University School of Medicine, United States. [4]Division of Bone and Mineral Diseases, Washington University School of Medicine, United States. [3]Mallinckrodt Institute of Radiology, Washington University School of Medicine, United States. [4]Division of Bone and Mineral Diseases, Washington University School of Medicine,

SP7 encodes the osteoblast-specific transcription factor osterix, which is critical for osteoblast development and function. In 2020, we reported (Whyte et al. Bone 137:115364) a de novo SP7 missense mutation (c.926C>G, p.S309W) in a young woman with high bone turnover resembling juvenile Paget's disease (JPD). JPD features rapid bone remodeling throughout the skeleton, presents in infancy or early childhood with fractures and deformity, is characterized by elevated serum alkaline phosphatase (ALP), and is usually caused by recessive mutations in TNFRSF11B encoding osteoprotegerin (OPG). She began fracturing her lower extremity long bones during infancy, then developed skull deformity and hearing loss. At age 15, radiographs revealed generalized osteosclerosis, hyperostosis, scoliosis, and craniofacial/dental defects, and DXA showed elevated bone mineral density (Z-score +5.1 at lumbar spine and T-score +3.3 at wrist). Bone turnover markers (serum ALP and urine hydroxyproline) were elevated. Iliac crest biopsy was consistent with rapid skeletal remodeling. She responded to alendronate therapy. Sanger sequencing of the OPG gene was negative, whereas whole exome sequencing identified the SP7 variant S309W. Independent publication of a second patient with the identical mutation and similar clinical characteristics supports the SP7 neomorphic variant as causal. Herein, we created a zebrafish model of our patient's allele using CRISPR/cas9, called sp7stl838. The homozygous mutants and heterozygous siblings exhibit frequent scoliosis of caudal vertebra. Initial micro computed tomography analysis of homozygous mutant and WT sib showed altered vertebral morphology, teeth not mounted in bone, and fractures in the caudal (tail) fin. Additionally, the mutant fish have altered growth of the premaxilla, maxilla, and dentary and other bones in the head. Cranial sutures between the frontal plates of the neurocranium ridge-up rather than overlap as in WT. The mid-region of the face centered on the nose, appears to have reduced bone density, while scales (which are dermal bone) have increased bone density. Histologic staining for bone and cartilage shows early excessive mineralization due to overactive sp7 (see figure). Thus, the zebrafish sp7 allele recapitulates some of our patient's JPD, with additional features. Our findings confirm c.926C>G, p.S309W as the causal mutation for Type 4 JPD and provide a good model for further study of this SP7 neomorphic mutation.

Altered Desensitization of PTHrP Signaling as a Mechanism for Delayed Ossification in Eiken Syndrome *Ignacio Portales Castillo[1], Jakob Hoeppner[2], Thomas Dean[2], Brendan Creemer[3], Ross Cheloha[3], Sofya Savransky[4], Jean-Pierre Vilardaga[5], Roberto Civitelli[6], Harald Jueppner[2], Thomas Gardella[2]. [1]Washington University St. Louis, . [2]Massachusetts General Hospital, United States. [3]Chemical Biology in Signaling Section, Laboratory of Bioorganic Chemistry, National Institutes of Diabetes and Digestive and Kidney Diseases, United States. [4]Department of Pharmacology and Chemical Biology, School of Medicine, University of Pittsburgh, United States. [5]University of Pittsburgh, School of Medicine, United States. [6]Washington University in St. Louis School of Medicine, United States

Eiken syndrome is a rare disease characterized by delayed bone mineralization that is caused by homozygous mutations in the parathyroid hormone/PTH-related protein receptor (PTH1R). In some cases, hypocalcemia with elevated serum PTH also occurs. These clinical features seem consistent with a gain-of-function (G-O-F) effect of the mutation, given that the PTH1R acts during endochondral bone formation in response to PTHrP to delay growth plate chondrocyte differentiation and prevent premature ossification, and throughout life in response to PTH to maintain calcium homeostasis. The mechanisms, however, by which the PTH1R mutations of Eiken syndrome result in altered bone development and mineral ion physiology are unknown. The main signaling pathway activated by the PTH1R in response to either endogenous ligand is cAMP, which is normally regulated at least in part by interaction with ?arrestins. Here, we present results of our assays in vitro of three reported PTH1R mutations (R485X, E35K and Y134S) of Eiken syndrome which support a G-O-F effect of the mutations on cAMP signaling and suggest a plausible mechanism to explain the delayed bone mineralization phenotype. In HEK293 cells, and compared to PTH1R-WT, PTH1R-R485X, which has a truncated C-terminal tail and hence lacks important sites of ?arrestin interaction, exhibited elevated basal and prolonged PTHrP-induced cAMP signaling responses. The E35K and Y134S mutants, which are altered in the receptor's extracellular N-terminal domain at or near key sites of ligand contact, exhibited little or no change in

initial rates of PTHrP-induced cAMP signaling, but signaling after washout of unbound PTHrP was reduced, leading to a blunted desensitization response to PTHrP re-exposure. Each mutant was defective for recruiting ?arrestin2 to endosomes, but the defect for E35K and Y134S was specific for stimulation with PTHrP, not PTH; defects which parallel the impaired termination of initial PTHrP-induced cAMP signaling (R485X) and the impaired desensitization to PTHrP re-exposure (E35K, Y134S). The combined results suggest that a G-O-F effect of the studied mutations on either the constitutive or PTHrP-stimulated cAMP signaling by the PTH1R due in part to a weakened interaction with ?arrestin2 is a plausible mechanism underlying the delayed ossification seen in these Eiken syndrome patients.

The dynamics of P3 bone regeneration are compromised in Ts65 male Down syndrome mice *KIRBY M. SHERMAN[1,] CATRINA SILVEIRA[1,] Abigail Leon[3,] Hannah M. Smith[3,] Mingquan Yan[3,] Ken Muneoka[3,] Dana Gaddy[4,] Larry Suva[5,] Lindsay Dawson[6,] [1]Texas A&M University , [3]Texas A&M University, United States, [3]Texas A&M University, [4]College of Veterinary Medicine, Texas A&M University, United States, [5]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States, [6]Texas A&M University College of Veterinary Medicine, United States

Down Syndrome (DS), trisomy of human chromosome 21 (Ts21) is associated with mammalian embryologic and postnatal abnormalities. Ts21 individuals typically exhibit hallmark skeletal defects such as low bone mineral density (BMD) that predisposes this vulnerable group to skeletal injuries. Using multiple DS mouse lines that parallel the low BMD observed in Ts21 patients, Dp16(16)1Yey (Dp16) and Ts65Dn, transformative progress has been made in determining how low BMD in DS translates to skeletal repair. We demonstrated that fracture healing is severely impaired in Dp16 mice, with a nearly 100% occurrence of fracture non-union, characterized by failure of the cartilaginous callus to bridge the fracture gap. Underscoring the clinical relevance of our observations using murine DS lines, a fracture non-union was recently reported in a Ts21 patient. Here, to investigate intramembranous bone regeneration in DS, Ts65Dn male mice and WT controls were subjected to distal amputation of the digit tip (P3) and assessed via longitudinal ?CT and histological analysis. In this model, targeted osteoclast and osteoblast activities are spatially and temporally separated in vivo over the course of intramembranous bone regeneration. To fine-tune the analysis of P3 regeneration in the DS setting, we deployed our in-vivo ?CT staging system that distinguishes the 5 stages of the regeneration response based on osteoclast- and osteoblast-mediated anatomical changes.After P3 amputation, Ts65Dn males (n=8) show significantly delayed bone resorption and attenuated P3 bone regeneration compared to WT males (n=16; P<=0.0001). Intriguingly, ?CT staging revealed that osteoclast recruitment and the initiation of osteoclastic resorption (stage 2) was temporally indistinguishable between DS and WT mice, yet osteoclast resorption (stage 3) is prolonged in DS mice. Histological and ?CT analysis revealed that DS mice progress to stage 5 (initiation of bone regeneration) slower than WT mice, consistent with defects in osteoblast recruitment and/or activity. The osteoblast defect does not resolve, and Ts65Dn mice never achieve WT bone regeneration volume, even 2 months post amputation.Collectively, these data demonstrate that both intramembranous bone regeneration and endochondral fracture healing are severely impacted in DS mice. Future studies to identify the cellular and molecular deficits inherent in DS bone repair are critical to enable bone repair treatment options in people with Ts21.

Respiratory Distress in Hypophosphatasia: The Case for Defects in Lung and Diaphragm in HPP Sheep *CLAIRE STENHOUSE[2,] JOSHUA BERTELS[2,] ALYSSA FALCK[3,] Lauren White[2,] Yava Jones-Hall[2,] Larry Suva[4,] Dana Gaddy[5,] [2]Texas A&M University, United States, [2]Texas A&M University, [3], United States, [4]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States, [5]College of Veterinary Medicine, Texas A&M University, United States

Hypophosphatasia (HPP) is an inherited disorder of mineral metabolism in individuals with loss of function mutations in the tissue-nonspecific alkaline phosphatase gene (ALPL). Patients with severe HPP have low serum ALPL enzymatic activity, musculoskeletal defects, and respiratory complications. We created a sheep model of HPP that recapitulates the human HPP phenotype. Interestingly, neonatal HPP lambs commonly have respiratory complications at birth and an increased incidence of developing pneumonia compared to wildtype (WT) control lambs. Prophylactic antibiotic administration to 1-day old lambs increased survival rates of HPP sheep to >1 year of age without evidence of respiratory symptoms (wheezing, labored breathing, nasal discharge). To better characterize the respiratory phenotype of HPP sheep, WT and homozygous HPP sheep were sacrificed at 1 year of age, and lung pathology, diaphragm function and rib mineralization assessed. Lung histology demonstrated pathologies consistent with pleural fibrosis, emphysema, and congestion in HPP sheep despite no respiratory symptoms at the time of sacrifice. Interestingly, rib mineralization in HPP sheep was indistinguishable from WT as measured by DEXA and microCT. However, isolated diaphragm muscle fibers from both genotypes demonstrated increased stiffness in 1-year old HPP sheep compared to WT, suggesting that compromises in diaphragm function also contribute to respiratory complications in HPP. To determine if the observed postnatal respiratory deficiencies were also apparent during development, lungs and rib mineralization were assessed in WT and HPP fetuses on gestational Day 100 (GD100). Like 1 year old HPP sheep, significant lung pathology was present on GD100, and fetal rib mineralization was not different between genotypes. These data provide the first direct evidence that the postnatal HPP lung phenotype is programmed during fetal development. Collectively, these data in HPP sheep demonstrate that the postnatal HPP respiratory phenotype has origins during fetal development and suggest that respiratory distress syndrome in human HPP is not solely the result of impaired rib mineralization and may also involve defects in both lung and diaphragm development and function. The observed abnormalities in multiple tissues that contribute to asymptomatic respiratory deficiencies in HPP suggest the potential need for monitoring or managing underlying respiratory deficiencies in mild to moderate HPP patients.

Prkar1a deletion in osteoblasts causes severe bone pathology with change in gene expression leading to impairment of osteoblast differentiation and increased osteoclast activity. *CAROLE LE HENAFF[2,] ZHIMING HE[2,] Brandon Finnie[2,] Joshua Johnson[2,] Maria Pacheco[2,] Yasaman Nahaei[2,] Juhee Jeong[2,] Henry Kronenberg[3,] Lawrence S Kirschner[4,] Nicola Partridge[5,] [2]New York University, United States, [2]New York University, [3]Massachusetts General Hospital, United States, [4]Department of Cancer Biology and Genetics, Division of Endocrinology, Diabetes, and Metabolism, Department of Internal Medicine, The Ohio State University, United States, [5]New York University College of Dentistry, United States

PTH (1-34) was the first osteoanabolic hormone for treating osteoporosis. PTH acts through PTHR1 and Protein Kinase A (PKA) activation to regulate osteoblastic gene expression. However, hyperactive PTHR1 and its downstream signaling pathway (Gs?) are involved in several bone diseases including hyperparathyroidism, Jansen's metaphyseal chondrodysplasia and Fibrous Dysplasia-McCune-Albright Syndrome. Hyperactive PKA due to a mutation in PKA regulatory subunit 1A (Prkar1a) is found in Carney disease and has been linked to benign tumor formation while its impact on bone formation or remodeling remains unknown. Our study aimed to elucidate the effects of increased PKA activity and better understand the actions of PTH in bones. One-month-old C57Bl/6J male and female col1CREERT/Prkar1afl/fl mice or Prkar1afl/fl mice received tamoxifen weekly for 3 weeks to delete Prkar1a in osteoblasts and increase PKA activity. In both sexes, Prkar1aob-/- mice demonstrated bone pathologies in their skulls, femurs and vertebrae and tumors in their tails. MicroCT showed cortical bone breakdown with apparent trabecular bone in the cortical area in femurs, vertebrae, tails and skulls. RNA-Seq was conducted with femoral trabecular bone. The data showed a complete change in gene expression and an impairment of osteoblast differentiation with a defect in ossification. This was confirmed by qPCR analyses. In both sexes, cortical and trabecular bone RNAs showed a large increase in Bsp mRNA levels (3-6 fold) with a sharp decrease in Bglap (0.2-0.4 fold) showing a change in osteoblast differentiation. The RNAseq and qPCR confirmed the high bone turnover in Prkar1aob-/- mice with a 2-3 fold upregulation of Rankl. These paralleled the huge increase in osteoblast activity shown by serum-P1NP levels (6.5-13 fold), only single fluorescent labeling and a substantial increase in osteoclast activity shown by CTX levels (4.4-12 fold) and TRAP staining (increased osteoclast number and size). Furthermore, PTH-responsive-genes were significantly changed: Sost expression was decreased to 0.1-0.2 fold, and Mmp13 was increased by at least 3 fold. It was evident that there was a profound modification of gene expression of chemokines and Wnt members together with enhanced osteoclastogenesis. High PKA activity in osteoblasts appears to be involved with high bone turnover and pathological events mimicking diseases from a hyperactive PTHR1/PKA pathway.

PDGFR? Signaling in Osteoprogenitors Contributes to the Pathogenesis of Fibrous Dysplasia *Cyril Thouverey[1,] Alessandro Corsi[2,] Mara Riminucci[3,] [1]University Hospital of Geneva, Switzerland, [2]Sapienza University, Italy, [3]University La Sapienza, Italy

Fibrous Dysplasia (FD) is a rare bone disorder caused by somatic gain-of-function mutations of the GNAS gene, which encodes Gs? protein. FD bone lesions are characterized by the replacement of normal bone and marrow by a fibro-osseous tissue containing proliferating fibroblast-like osteoprogenitors (OPs) and elevated number of osteoclasts. Platelet-derived growth factor B (PDGFB) and PDGF receptor type ? (PDGFRB) are overexpressed in human FD bone lesions. To determine whether PDGF/PDGFR? signaling contributes to FD pathogenesis, we generated a mouse model of FD that lacks PDGFR? in leptin receptor-positive (LEPR+) OPs (GnasR201C;Lepr-Cre;Pdgfrbf/f) and compared its phenotype with that of Lepr-Cre and GnasR201C;Lepr-Cre mice at 5 months of age. Bone phenotypes were analyzed by micro-CT, 3-point bending test, histomorphometry and gene expression analyses. Bone lesions of GnasR201C;Lepr-Cre mice exhibited increases in Pdgfb (+65%, p=0.06) and Pdgfrb (+139%, p=0.06) expressions in comparison to healthy bone tissue of Lepr-Cre littermates. GnasR201C mice showed increased cortical bone vol-

ume (+39%, p=0.028) with elevated number of osteolytic cavities (x14.3 per total volume, p=0.0001), decreased cortical volumetric bone mineral density (vBMD; -2%, p=0.04), and altered bone mechanical properties (plastic energy: -55%, p=0.005) at femoral midshaft lesions. Deletion of PDGFR? in LEPR+ cells in GnasR201C mice decreased number of osteolytic cavities (-62% vs GnasR201C;Lepr-Cre, p=0.002), augmented cortical vBMD (+1.2% vs GnasR201C;Lepr-Cre, p=0.04) and restored bone mechanical properties (plastic energy: +107% vs GnasR201C;Lepr-Cre, p=0.02). Those beneficial effects were associated with reduced osteoclast number (-44% vs GnasR201C;Lepr-Cre, p=0.0001), osteoid surfaces (-63% vs GnasR201C;Lepr-Cre, p=0.002) and fibrotic bone marrow volume (-66% vs GnasR201C;Lepr-Cre, p=0.02). Consistent with these findings, bone lesions of GnasR201C;Lepr-Cre;Pdgfrbf/f mice displayed reduced expressions of Rankl (-55%, p=0.02), Csf1 (-74%, p=0.003), fibronectin (-61%, p=0.06) and Timp1 (-77%, p=0.007) in comparison to those of GnasR201C;Lepr-Cre mice. In conclusion, our results indicate that PDGFR? signaling in OPs contributes to the pathogenesis of FD.

Bone Marrow Adiposity May Be a Key Player in Cystic Fibrosis related Bone Disease *Claire Dumortier[1], Johan Sergheraert[1], Mezhoura Ouhamou[1], Olivier Piot[2], Emilie Buache[2], Nicolas Goffin[2], Christophe Chauveau[3], Sophie Gangloff[1], Denise Al Alam[4], Frédéric Velard[1]. [1]URCA, EA 4691 BIOS, France. [2]URCA, EA 7506 BioSpeCT, France. [3]ULCO, ULR 4490 MabLab, France. [4]The Lundquist Institute, Torrance, Harbor-UCLA Medical Center, United States

Purpose: Cystic Fibrosis related Bone Disease (CFBD) affects 50% of cystic fibrosis (CF) adult patients. Osteoblasts obtained from CF patients' induced pluripotent stem cells (iPSCs) evidenced delayed maturation phenotype as already observed on primary mature cells (Velard, 2014; Delion, 2016). They have also shown an higher level of PPARG (the adipocyte transcription factor) than healthy donors-derived control line. A relationship exists between low bone density and increased medullar adiposity in several pathologies (Verma, 2002; Piccinin, 2014, Schafer, 2015; Bredella, 2009). So, we hypothesised that adipocyte differentiation would be triggered in cells bearing mutation in CFTR gene, which causes CF. Up to date, medullar adiposity has never been investigated in CFBD.Methods: Bone marrow mesenchymal stem cells (MSC) from non CF patients have been differentiated into adipocytes during 21 days with or without Inh172, a CFTR pharmacological inhibitor. Oil Red'O, Bodipy®, Perilipin, FABP4 (adipocytes specific proteins) and PPARG stainings were performed. RAMAN microspectroscopy was used to assess lipid content. MicroCT analysis of 10 weeks-old F508del CFTR mice was performed to determine bone marrow adiposity. Results: Lipid vesicles were 50% bigger when CFTR inhibitor was adding in the medium (n=6 donors, p<0.05). However, no change in PLIN1, FABP4 and PPARG genes or protein expression, or adiponectin and leptin secretion were highlighted. Lipid droplets spontaneous generation was evidenced by RAMAN, Oil Red O and BODIPY stainings, in MSC cultured in presence of Inh172 and without any differentiation triggering factors. This reflects the spontaneous adipocyte commitment of MSC associated with impaired CFTR function. In addition, we evidenced increased bone marrow adiposity in mice bearing F508del CFTR mutation compared to wildtype littermates.Conclusion: These data are the first proof of concept that CFTR loss of function influences size and content of mature adipocytes lipid vesicles, as well as MSC commitment towards adipocyte lineage. More, increased bone marrow adiposity observed in CF mice tibia enforced the idea of a defective lipid metabolism in CF context, sustained by recent studies that have highlighted the major role of lipid deregulations on CFTR function (Aureli, 2016. Loberto, 2020). The hypothesis of increased medullar adiposity in CF patients is a promising axis to better understand and cure CFBD.

SUN-542

GNAS AS2 DMR Methylation Depends on STX16/NESP55 ICRs and Has Diagnostic Potential in AD-PHP1B *YORIHIRO IWASAKI[1], Monica Reyes[2], Harald Jueppner[3], Murat Bastepe[4]. [1], . [2]Massachusetts General Hospital , United States. [3]Massachusetts General Hospital, United States. [4]Massachusetts General Hospital, Harvard Medical School, United States

BACKGROUND: Gs? is a signaling protein essential for the actions of numerous hormones. It is encoded by GNAS, an imprinted locus giving rise to Gs? mRNA and alternatively spliced transcripts from additional first exons within differentially methylated regions (DMRs), including NESP55, antisense (AS), XL, and A/B. Parent-specific methylation of these GNAS DMRs is crucial for Gs? expression and the pathogenesis of diseases caused by GNAS mutations. Perturbed GNAS methylation, especially A/B hypomethylation, leads to pseudohypoparathyroidism type 1B (PHP1B). We recently generated human embryonic stem cell (hESC) models of autosomal dominant PHP1B (AD-PHP1B) by deleting either of the two GNAS imprinting control regions (ICRs), namely del-STX16 and del-NESP55. These models revealed that interaction between the two GNAS ICRs is critical for regulating A/B methylation in the zygote/early embryo. Recently, a new DMR located between AS and XL (AS2) was shown to be hypomethylated in some PHP1B variants.METHODS: We analyzed AS2 methylation levels in wild-type (WT), del-STX16/del-NESP55 hESCs using MSRE-qPCR. We also analyzed GNAS methylation by MS-MLPA in several AD-PHP1B patients with either a STX16 deletion, a GNAS-STX16 duplication upstream of AS2, or a retrotransposon insertion downstream of AS2.RESULTS: In WT hESCs, the AS2 DMR had lower methylation levels than other GNAS DMRs (~3.5 vs. ~50%). Maternal deletion of STX16- or NESP55-ICRs resulted in further hypomethylation at AS2 DMR (3.6 vs. 0.03%, p<0.0001 for del-STX16; 3.5 vs. 0.6%, p=0.0015 for del-NESP55). In contrast, methylation levels at AS and XL were not significantly reduced. AS2 was hypomethylated in AD-PHP1B patients with a STX16 deletion (n=7) or a GNAS-STX16 duplication (22.2+/-4.7% and 18.1%, respectively), but it was normal (53.7+/-1.5%) in seven patients from one family with a retrotransposon insertion. DISCUSSION: Based on our findings, the AS2 DMR, unlike AS and XL DMRs, is critically regulated by GNAS ICRs in the zygote/early embryo, similar to A/B DMR. In addition, the extent of GNAS methylation abnormalities, including AS2 hypomethylation, depends on the locations of genomic aberrations that presumably disrupt nascent NESP55 transcripts. Thus, analysis of AS2 DMR can help determine where a disease-causing AD-PHP1B mutation is located within GNAS/STX16.

Human Femur Erlenmeyer Flask Deformities Result from Disrupted Metaphyseal Bone Modeling with Mutations in ANKH, COL10A1, FLNA, LRRK1, MMP9, MMP13, PLEKHM1, PTH1R, SFRP4 and SNX10 *Robert Brommage[1]. [1]BoneGenomivs, United States

Metaphyseal dysplasias involve defects in metaphyseal bone development, usually with normal stature and minimal growth plate disturbances. These genetic disorders include craniometaphyseal dysplasia (ANKH, mouse Ank), Schmid metaphyseal chondrodysplasia (COL10A1), frontometaphyseal dysplasia (FLNA), Gaucher's disease (GBA), osteosclerot-

ic metaphyseal dysplasia (LRRK1), metaphyseal anadysplasia (MMP9 and MMP13), Jansen metaphyseal chondrodysplasia (PTH1R), Pyle's disease (SFRP4), and osteopetroses resulting from PLEKHM1 and SNX10 mutations. Disruptions of the homologous mouse genes result in similar metaphyseal abnormalities.Metaphyseal bone modeling during growth involves 1) endocortical bone formation, 2) periosteal bone resorption, 3) consolidation of existing peripheral trabeculae into cortical bone and 4) removal of central trabeculae from marrow regions. The Erlenmeyer flask deformity (see attachment) results from disruption of these processes.During linear growth periosteal osteoclasts below the growth plate resorb bone to decrease bone width. Osteoblasts simultaneously add bone to endocortical surfaces, which includes incorporation of existing trabeculae (compactation). Small islands of calcified cartilage remain within this cortical bone. Calcified cartilage below the growth plate is transformed to mineralized bone trabeculae, which are then resorbed several centimeters from the growth plate. A full understanding of the normal spatial and temporal coordination of these complex processes must include the actions of each of these known metaphyseal dysplasia genes.Developmental metaphyseal dysplasias occur when these processes are compromised. Radiologic Erlenmeyer flask deformities (EFD) with thin cortices result from failure of periosteal osteoclasts to resorb bone and concurrent lack of bone formation by endocortical osteoblasts. Metaphyseal trabeculae within the marrow cavity are not properly removed.A literature survey of 55 publications (92 subjects) describing skeletal phenotypes in Pyle's disease subjects found EFD (all publications), genu valgum (36), thin cortices (28), S-shaped tibia (23), fragility fractures (19), and dysplasias in skulls, clavicles, ribs, and digits (all > 20).Mouse mutants provide good models for these human dysplasias. Mouse gene knockouts of Lrrk1 and Sfrp4 were observed (in the author's laboratory) to have relevant bone abnormalities prior to the identification of human LRRK1 and SFRP4 mutations.

Circulating 25(OH)D >= 50 ng/mL is Not Associated With Increased Falls

*Neil Binkley[1], Gretta Borchardt[2], Joan Lappe[3], Chris Sempos[4]. [1]University of Wisconsin, Madison, United States. [2]University of Wisconsin, United States. [3]Creighton University, United States. [4]Vitamin D Standardization Program, United States

Purpose: Falls are a common cause of unintentional injury including fracture in older adults. High circulating 25(OH)D has been reported to increase falls risk; thus, recent osteoporosis Guidelines recommend 25(OH)D not exceed 50 ng/mL. The purpose of this secondary analysis of a 4-year randomized trial of vitamin D supplementation in postmenopausal women was to evaluate the association of retrospectively standardized 25(OH)D concentration with falls.Methods: This study recruited 2,303 healthy postmenopausal women age 55+ in rural Nebraska. Excluding missing data (n=194) 2,109 were followed for 4 years. The treatment group received vitamin D3 2000 IU/daily. Circulating 25(OH)D was measured at baseline and annually initially using the Diasorin Liaison; subsequently, retrospectively standardized 25(OH)D (s25D) results were obtained using stored sera analyzed by HPLC following the Vitamin D Standardization Program protocol. Falls were captured by diary. Incidence for >=1 fall and >= 2 falls was assessed by study year and correlated with 4 levels of s25D (<= 20 ng/mL, 20-29 ng/mL, 30-49 ng/mL and >= 50 ng/mL) at start of each year. Subsequently association between s25D and falls was evaluated using multivariable logistic regression.Results: Mean baseline age was 65 (range 55-91) years. Mean (SD) s25D at baseline was 32.6 ng/mL (8.3) with no difference between treatment and placebo groups. s25D remained stable in the placebo group and increased to 41.3 ng/mL at year 1 in the treatment group then remained stable. Falls incidence rate did not differ by treatment group. At each individual year 1-4 and over the entire study duration the incidence rate for one or more falls varied from 19.3-36.4% and for 2 or more falls from 4.5-14.6%. Over all 4 years of follow-up there was a statistically significant association between s25D and falls incidence (both >=1 fall and 2 or more falls per year). This significant association appears to have been driven by lower falls rates in the < 20 ng/mL group. In the multivariate analysis, no consistent effect of s25D group on falls was observed.Conclusion: In this cohort of postmenopausal women, higher s25D concentration was not associated with greater falls risk.

Table: Crude falls incidence by standardized 25(OH)D group

	Study year				
s25D	1	2	3	4	All Years*
One or more falls/year [≥ 1 falls/year]					
< 20	19.3 (23/119)	20.9 (14/67)	24.7 (18/73)	19.7 (14/71)	*20.9 (69/330)
20-30	25.4 (171/674)	27.6 (141/511)	25.2 (121/480)	29.5 (122/413)	26.7 (555/2078)
30-50	27.6 (348/1261)	27.7 (337/1217)	29.1 (338/1164)	29.0 (333/1150)	28.3 (1356/4792)

Sarcopenia definitions And their Association with Non-fracture injurious Falls in older Swedish women From the SUPERB study

*Anoohya Gandham[1], GIULIA GREGORI[2], Lisa Johansson[3], Helena Johansson[4], Nicholas Harvey[5], Liesbeth Vandenput[6], Eugene McCloskey[9], JOHN KANIS[8], Marian Schini[9], Henrik Litsne[4], Kristian Axelsson[10], Mattias Lorentzon[11]. [1]Mary MacKillop Institute for Health Research, Australian Catholic University, Victoria, Australia, Australia. [2]University of Gothenburg, . [3]Institute of medicine, . [4]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Sweden, Sweden. [5]University of Southampton, . [6]Australian Catholic University, Australia. [9]University of Sheffield, United Kingdom. [8]UNIVERSITY OF SHEFFIELD, United Kingdom. [9]University of Sheffield, . [10]Institute of Medicine, Sahlgrenska Academy, Gothenburg University, . [11]Sahlgrenska Academy, University of Gothenburg, Sweden

Purpose: To investigate the prevalence and predictive value of three commonly used sarcopenia definitions for the risk of injurious falls in a population of older Swedish women, when adjusted for fracture risk assessment (FRAX)-based risk factors and previous falls. Methods: Of 3,028 older women aged 75 to 80 years included in the Swedish SUPERB-cohort, 2,883 had complete data on the used sarcopenia definitions and were used in all further analyses. Sarcopenia was defined based on the Sarcopenia Definitions and Outcomes Consortium (SDOC) (low handgrip strength and gait speed), revised European Working Group on Sarcopenia in Older People (EWGSOP2) and Asian Working Group for Sarcopenia (AWGS) (low appendicular lean mass index (ALMI; appendicular lean mass (kg)/height (m2)) and hand grip strength (kg))) definitions. ALMI was obtained from dual-energy X-ray absorptiometry (Hologic Discovery A). Self-reported questionnaires captured the occurrence of falls in the past 12 months and FRAX-based clinical risk factors. Incident injurious falls, without concurrent fracture, were identified using national registers and ICD-10 codes (W00-W19 code and a S00-T14 diagnosis, but not a simultaneous fracture code). Cox regression (hazard ratios (HR) and 95% confidence intervals (CI)) analyses were performed without adjustment and after adjustment for age, FRAX variables and previous falls. Results: Sarcopenia prevalence was 4% (n=129) defined by SDOC, 12% (n=360) according to EWGSOP2 and 10% (n=296) for AWGS. During a median (IQR) follow-up time of 6.6 (5.7-7.3) years there were 491 injurious falls without fracture. Sarcopenia according to EWGSOP2 and AWGS was not associated with an increased risk of injurious falls in any model, regardless of adjustment (p >0.05). Individuals with sarcopenia defined by SDOC had a more than 2-fold increase in the risk of injurious falls compared with women without sarcopenia (HR: 2.27; CI:1.64-3.15). Adjusting this model for clinical risk factors used in FRAX and previous falls resulted in a slightly attenuated association between SDOC prevalence and injurious falls (HR:1.85; CI:1.32-2.60). Conclusion: These findings suggest that sarcopenia definitions confined to muscle function and strength such as SDOC, rather than including DXA-based ALMI (EWGSOP2 and AWGS), lowers the prevalence but improves prediction of injurious falls in this population of Swedish older women.

Cross-calibration of body composition between Hologic and Inbody 970 *Ha Young Kim[1], Deog-Yoon Kim[2], Yong-Chan Ha[3], Hyoung-Moo Park[4], Dong-Won Byun[5], Young-Kyun Lee[6]. [1]Gangneung Asan Hospital, University of Ulsan College of Medicine, , Republic of Korea. [2]Kyung Hee University Hospital, Republic of Korea. [3]Seoul Bumin Hospital, Republic of Korea. [4]Grace Hospital, Republic of Korea. [5]Soon Chun Hyang University Hospital, Republic of Korea. [6]Seoul National University Bundang Hospital, Republic of Korea

Background: The aim of this study was to investigate the correlation body composition measured by the Hologic Discovery QDR W and the Inbody 970 and to calculate the conversion rate between the two devices. Methods: The 120 subjects were men and women in aged 20-79 years old. All participants were scanned twice on both the Hologic Discovery QDR W (Hologic, Bedford, MA) DEXA system and the Inbody 970 (Biospace Co., Seoul, Korea) using the manufacturers' standard scanning and positioning protocols. Results: In the correlation coefficient for muscle mass between the two devices, all regions showed a very high correlation of 0.9 or more. The values were 0.96 (0.95 - 0.98) for the right arm, 0.96 (0.94 - 0.97) for the left arm, 0.96 (0.95 - 0.97) for the right leg, and 0.97 (0.95 - 0.98) for the left leg. body composition analysis of two machines by gender was compared. In the CCC for muscle mass between the two devices in woman, all regions showed moderate or strongly correlation. Body composition analysis of two machines according to age of each sex was compared. The CCC values of total muscle mass in female were 0.69 (0.46 - 0.83) in age 18 - 34, 0.66 (0.5 - 0.77) in age 35 - 64 and 0.36 (0.11 - 0.56) in age over 65. Conclusion: This prospective comparision study between DXA and BIA demonstrated that BIA is an good laternative device for measuring muscle mass and diagnosing sarcopenia. However, relatively lower correlation in gender and age differences between two device should be considered.

Correlation between serum immunoglobulin E levels and skeletal muscle mass in Korean adults: a cross-sectional study *Hyeonmok Kim[1]. [1]Seoul medical center, Republic of Korea

Despite evidence from experimental and field studies suggesting the detrimental effects of serum immunoglobulin E (IgE) on muscle metabolism, there are limited clinical studies in terms of circulating IgE with sarcopenia-related phenotypes. Thus, this study investigated the correlation between serum IgE levels and indices of muscle mass and risk of sarcopenia. This is a population based cross-sectional study from the Fifth Korea National Health and Nutrition Examination Surveys (KNHANES V), which includes participants a total of 2,241 (1,115 men and 1,126 women). Total lean mass (TLM) and appendicular skeletal muscle mass (ASM) was measured by dual energy X-ray absorptiometry.The findings demonstrates that before and after adjustment for confounding variables, higher IgE levels were significantly associated with lower ASM/Weight in men (r=-0.064, P=0.034) and with lower TLM and ASM/Weight in women (r=-0.069, P=0.035 and r=-0.089, P=0.006, respectively). When participants were divided into two groups according to sarcopenia status calculated by ASM/Weight, participants with sarcopenia demonstrated 88.4% and 121.8% higher serum IgE levels than those without sarcopenia (P<0.001 and P<0.001, respectively). The risk of sarcopenia of men and women were 3.41 fold and 5.69 fold (95% confidence interval=1.45-8.01 and 1.49-21.82 respectively) higher in subjects with in the highest serum IgE quartile than in those in the lowest quartile after adjustment for potential confounders.These findings suggests that increased serum IgE levels could be an independent risk factor for the development of low muscle mass, especially skeletal muscle mass.

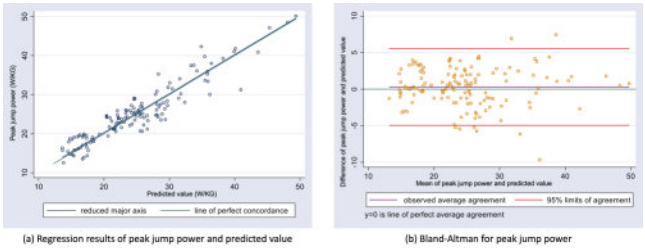
SUN-551

Jump power assessment using computer vision-based deep learning motion analysis to detect possible sarcopenia *Sang Wouk Cho[1], Eun-young Park[2], Na-rae Park[2], Sookyeong Han[3], Yumie Rhee[4], Namki Hong[5]. [1]Department of Integrative Medicine, Yonsei University College of Medicine, Republic of Korea. [2]Department of Internal Medicine, Endocrine Research Institute, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea , Republic of Korea. [3]Department of Internal Medicine, Endocrine Research Institute, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of Korea. [4]Yonsei University College of Medicine, Republic of Korea. [5]Division of Endocrinology, Republic of Korea

Peak countermovement jump power measured using ground force plate is associated with impaired physical function and higher risk of fracture in older adults. However, ground force plate is available at research setting, limiting the clinical applicability. We developed a video-based pose landmark regression model to estimate the peak jump power and tested clinical utility for sarcopenia screening.Participants who visited Osteoporosis Clinic, Severance Hospital, Korea were prospectively enrolled after obtaining written consent between March and August 2022. Individuals were instructed to perform three jump attempts under video recording, followed by grip strength (GS) and 5-time chair rise test (CRT). After detecting anatomical landmarks using Mediapipe for each frame of jump motion videos, an open-source deep learning pose estimation model, velocity, acceleration, force, and power were estimated. LightGBM-based model was built to predict jump power from motion data in 80% train set. In 20% hold-out set, clinical utility of predicted jump power was tested against detecting possible sarcopenia by Asian Working Group for Sarcopenia 2019 definition (low GS or low CRT performance).A total of 661 jump motion data from 221 patients (mean age 62 years; 78% women; possible sarcopenia 45%) were analyzed. In test set, average difference between predicted and actual jump power was 0.27 W/kg (95% limit of agreement -4.9 to +5.5 W/kg; concordance correlation coeffficient 0.93). Lower predicted jump power was associated with elevated odds of possible sarcopenia (adjusted odds ratio 1.27, 95% CI 1.02 to 1.58, p=0.029) after adjustment for age, sex, and body mass index. Motion data-based predicted jump power showed better discriminatory ability compared to age (AUROC 0.71 vs. 0.63, p=0.021), with comparable discriminatory performance to actual jump power (0.71 vs. 0.74, p=0.096).Computer vision -based prediction of jump power using motion video data can be useful to detect possible sarcopenia.



(a) Regression results of peak jump power and predicted value (b) Bland-Altman for peak jump power

Vertebral Bone Marrow Fat Is Associated With Sarcopenia In Korean Older Adults *Seunghyun Lee[1], Jhii-Hyun Ahn[2], Namki Hong[3], Jae Seung Chang[4], Kyu-Sang Park[5], Moon Young Kim[6], Jung Soo Lim[7]. [1]Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, . [2]Department of Radiology, Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of Korea. [3]Division of Endocrinology, Republic of Korea. [4]Department of Sports Science, Hannam University, Daejeon, Korea, Republic of Korea. [5]Department of Physiology, Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of Korea. [6]Department of Internal Medicine, Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of Korea. [7]Yonsei University Wonju College of Medicine, Republic of Korea

Mesenchymal stem cells (MSCs) are precursors of adipocytes, osteoblasts, and myocytes. Recent studies suggested that vertebral bone marrow fat (vBMF) can be a diagnostic marker for osteoporosis, and it is explained by the competition of osteoblastogenesis and adipogenesis when MSCs are differentiated. However, the association between vBMF and sarcopenia or myokines remains unclear.Among 1,894 participants of a population-based cohort study between May 2018 and August 2019, a total of 310 subjects (114 men, 196 women) were enrolled. Those with alcoholism, a history of steroid use, liver diseases other than fatty liver, malignancy, high body mass index (BMI) (>= 35 kg/m2), high fasting blood glucose (>= 200 mg/dL), L-spine compression, metal artifact, and missing data were excluded. Bone mineral density and muscle mass (MM) were assessed by dual-energy X-ray absorptiometry. vBMF (%) was defined as the average of L1-3 proton density fat fraction using quantitative MRI. The presence of low MM, low muscle function (MF), and sarcopenia were defined based on the Asian Working Group Society 2019 guideline. Moreover, serum concentrations of myokines such as myostatin and decorin (DCN) were quantified by using commercially available ELISA kits according to the manufacturer's instructions. The median age was 66 [61-72] years, and BMI was 25.3 [23.4-27.5] kg/m2. Approximately 44%, 48%, and 23% of the subjects had low MM, low MF, and sarcopenia, respectively. Those with sarcopenia had higher vBMF than normal subjects (59.8 [56.0-62.4] vs. 55.0 [46.8-59.2], p<0.001). Higher vBMF had a higher prevalence of low MM, low MF, and sarcopenia according to unadjusted logistic regression analysis (all, p<0.05). However, there was an association between vBMF and low MM or sarcopenia after adjusting for covariates (adjusted OR 1.78 [1.10-2.89], p=0.020; adjusted OR 1.45 [1.01-2.08], p=0.044, respectively). For myokines, partial correlation analysis revealed a significant correlation between vBMF and DCN after adjusting for age group, sex, and BMI (r=0.200, p<0.001).Intriguingly, our findings suggest a link between vBMF and sarcopenia or DCN levels in Korean older individuals. Further research is needed to understand better how vBMF interacts with sarcopenia and myokines.

Physical Function Assessment in Older Adults- Self-Report May Not Reflect Actual Physical Performance *Jeri Nieves[1], Donald McMahon[4], Heather Berman[3], Peter Prescott[3], Felicia Cosman[4], Joseph Lane[3]. [1]Columbia University and Hospital for Special Surgery, , [4]Columbia University College of Physicians and Surgeons, , [3]Hospital for Special Surgery, United States, [4]Columbia University College of Physicians and Surgeons, United States

Introduction: Functional ability is a marker of successful treatment after fracture. Poor physical function is associated with high risk of another fracture. The methodology to assess functional ability varies greatly, from self-reported measures to physical performance tests; the gold standard is likely the Short Physical Performance Battery (SPPB). The aim of this study was to see if self-reported measures, using 3 separate scales, are a good proxy for tested performance. Methods: Subjects included patients enrolled in pelvic fracture healing study (n=64; SF-36 used) and patients recruited from our osteoporosis clinic into the Fragile Bone Registry (FBR; n=188; PROMIS-29 used). In-person testing of physical performance included SPPB-which combines 4-meter walk speed, time for 5 chair stands and ability to maintain balance in 3 positions) and Timed Up and Go (TUG- the time to stand, walk 3 meters, turn, and walk 3 meters back). Self-reported measures of physical performance: SF-36 physical function, PROMIS-29, and Lower Extremity Activity Scale Score (LEASS) were completed under supervision by a research assistant. Self reported measures and TUG were compared to SPPB. Results: In the FBR, of participants whose physical performance by SPPB scored in the lowest quintile, 27% were in the highest quartile for PROMIS ($p<0.001$ fisher's exact test) and the kappa (level of agreement) was 0.7. Similar findings were found for the LEASS. For subjects who tested in the highest quartile of TUG, 22% were in the lowest quartile by PROMIS ($p<0.001$ Fishers' Exact Test, Kappa = 0.72). From regression analysis, PROMIS explained 32% and LEASS explained 11% of the variance in SPPB. The other performance test, TUG, explained 48% of the variance in SPPB. PROMIS was able to explain 29% and LEASS explained 12% of the variance in TUG. In pelvic fracture patients we were able to assess the relationship between changes in SPPB, TUG and SF-36 over 8 weeks. The correlation between the % differences in SPPB and SF-36 over 8 weeks was $r=0.44$ ($p=0.002$). Change in SF-36 explained 19% of the change in SPPB (Shrout-Fleiss ICCR = 0.55). The ICCR between changes in SPPB and TUG was 0.49, but TUG change only explained 13% of SPPB change. Conclusion: SPPB is likely more responsive to change in physical performance than TUG. Self-reported assessments of lower extremity physical function may not be reflective of tested physical performance in either cross-sectional or longitudinal evaluations.

Mapping the context of sedentary behaviour (MAPS-B) in older adults who are frail: A feasibility study *Isabel Rodrigues[1], Rachel Swance[1], Suleman Tariq[1], Alexa Kouroukis[1], Jonathan Adachi[2], Steven Bray[1], Qiyin Fang[1], George Ioannidis[3], Dylan Kobsar[1], Carolyn Leckie[1], Alexander Rabinovich[1], Rong Zheng[1], Alexandra Papaioannou[1]. [1]McMaster University , Canada, [2]St. Joseph s Hospital/ McMaster University, Canada, [3]McMaster University, Canada

Older adults who are frail are likely to be sedentary. Individuals with frailty are also at higher risk of falls and fractures. Prolonged sedentary time can decrease muscle and bone strength. Prior interventions to reduce sedentary time in older adults have not been successful as there is little research about the context of sedentary behaviour. We determined the feasibility to measure context (posture, location, purpose, social environment) of sedentary behaviour among older adults who are frail. We defined "feasibility process" using recruitment (20 participants within two-months), retention (85%), and refusal (20%) rates and "feasibility resource" if the measures capture context and are all participants willing to use the measures. We conducted a mixed-methods longitudinal study. Context was assessed using activPAL4TM placed on the anterior mid-thigh to assess posture (e.g., sitting), a McMaster engineering indoor positioning system (IPS) to assess functional location in the home (e.g., kitchen), and the Activities Collected over Time over 24-hours [ACT24] diary to understand purpose and social environment. We chose three measures as one measure alone does not capture all domains of context. We assessed feasibility in winter and spring over 1 weekend and 2 weekdays. We approached ~80 individuals through physicians' offices, community posters, and newspaper/radio advertisements, and 58 expressed interest in the study. Of the 58 individuals, 37 (28 female, Morley frail score>2) declined to enroll citing medical mistrust or worsening medical health (64% refusal). We enrolled 21 participants (13 female, 19 Caucasian) within two months; mean age 72.3+/-5.8 years. Eighteen participants were frail and 3 prefrail and all participants had probable sarcopenia using the Fit-Frailty App; ~30% had osteoporosis or a prior fragility fracture. After the initial study visit, one participant withdrew citing medical mistrust with the devices and another withdrew after the winter period citing worsening health (95% retention). All participants were willing to use activPAL4TM and 12 completed ACT24 while eight preferred a hard-copy diary. The diaries were not completed with detail making it challenging to precisely time synchronize the diary to the other measures. Six participants used the IPS, although they cited difficulties utilizing the system. The other 15 participants were not comfortable setting up the IPS. We met our criteria for recruitment and retention but experienced high refusal rates. Linking data between measures was complicated due to timeframe misalignment. The diaries did not accurately capture purpose. Participants found it challenging to configure the IPS.

Opportunistic Computed Tomography Analysis Reveals Severe Muscle Degeneration in Critical Care Patients *Ainsley C.J. Smith[1], Kirsten N. Bott[2], Brandon M. Hisey[3], Chel H. Lee[4], Kevin J. Solverson[3], Christopher Grant[5], Steven K. Boyd[2], Christopher J. Doig[3], Sarah L. Manske[2]. [1]Department of Radiology, Cumming School of Medicine, University of Calgary; McCaig Institute for Bone and Joint Health, University of Calgary; Department of Biomedical Engineering, University of Calgary, Canada, [2]Department of Radiology, Cumming School of Medicine, University of Calgary; McCaig Institute for Bone and Joint Health, University of Calgary, Canada, [3]Department of Critical Care, Cumming School of Medicine, University of Calgary, Canada, [4]Department of Critical Care, Cumming School of Medicine, University of Calgary; Department of Mathematics and Statistics, University of Calgary , Canada, [5]Department of Critical Care, Cumming School of Medicine, University of Calgary; Department of Clinical Neurosciences, University of Calgary, Canada

Purpose: Muscle loss is a common complication of critical illness that can lead to long-term physical impairment and poor quality of life. However, it is unclear who is most susceptible to critical illness induced muscle loss. Computed tomography (CT) images are acquired at several time points during a patient's intensive care unit (ICU) stay. These CT images can be repurposed to evaluate muscle cross-sectional area (CSA), a measure of muscle loss, across different patient populations. The objectives of this study were to: 1) measure changes in muscle CSA over the course of critical illness using clinically acquired CT images and 2) determine risk factors associated with critical illness induced muscle loss.Methods: We retrospectively acquired abdominal CT scans of ICU trauma and sepsis patients. Patients were included if they had a CT scan within 48 hours of ICU admission (baseline) and a second CT scan taken >14 days later, prior to discharge (follow-up). We assessed mean psoas muscle CSA (cm2) by segmenting the psoas muscle at L3 using an automated segmentation algorithm with manual correction. We acquired patient demographic and illness-related information using electronic medical records.Results: Critical care patients (n = 43) had a median time between scans of 19 [IQR: 15, 25] days. Patients had a median psoas CSA of 14.10 [IQR: 9.79, 19.91] cm2 at baseline and a median psoas CSA of 10.76 [IQR: 8.46, 14.70] cm2 at follow-up ($p < 0.001$). Univariate regression revealed that muscle CSA loss was greater in trauma patients than sepsis patients ($p < 0.01$). Univariate regression indicated a trend towards greater muscle CSA loss in younger patients ($p = 0.05$) and in males compared to females ($p = 0.07$). Multivariate regression suggested that illness type (trauma or sepsis) had a greater impact on muscle loss than sex or age. Univariate regression found that patients with greater illness severity, assessed with APACHE-IV scores, trended towards greater percent change in muscle per day in the ICU ($p = 0.06$).Conclusion: Critical care patients experienced a mean 24% decline in psoas muscle CSA over the course of their ICU stay. Our results indicate that patients with more muscle at ICU admission, typically young males with traumatic injuries, may experience a greater absolute muscle loss. Future research should focus on establishing muscle CSA thresholds to determine who is at risk of severe weakness and may benefit most from preventative interventions.

Validation of a Fall Rate Prediction Model for Community-Dwelling Older Adults: A Meta-Analysis with three Cohorts *Christina Wapp[1], Anne-Gabrielle Mittaz Hager[2], Toni Rikkonen[3], Roger Hilfiker[2], Emmanuel Biver[4], Heikki Kröger[5], Serge Ferrari[4], Marcel Zwahlen[6], Philippe Zysset[1]. [1]ARTORG Center for Biomedical Engineering Research, University of Bern, Switzerland. [2]HES-SO Valais-Wallis, School of Health Sciences, Physiotherapy, Switzerland. [3]Kuopio Musculoskeletal Research Unit (KMRU), University of Eastern Finland, Finland. [4]Division of Bone Diseases, Department of Medicine, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Switzerland. [5]Orthopaedics and Traumatology, Department of Orthopaedics, Traumatology and Hand Surgery, Kuopio University Hospital, Finland. [6]Institute for Social and Preventive Medicine, University of Bern, Switzerland

Background: Since most of the fragility fractures in older adults are caused by falls, the risk of fracturing increases together with the number of falls. Accordingly, the prediction of an expected fall number potentially helps to identify individuals at risk of fragility fractures. So far, only a few studies have analysed the risk of falling with rate ratios that enable the calculation of an expected fall rate. This analysis aimed to meta-analyse three previously developed fall rate prediction models that included the history of falls as the main predictor. Methods: The three cohorts GERICO [1], Swiss CHEF Trial [2] and Kuopio Fall Prevention Study [3] were used for a two-stage meta-analysis. Separate fall rate prediction models have been developed previously. All three models included the number of falls during 12 months prior to the baseline as a predictor, which was treated as a factor with 0, 1, 2, 3, 4 or >= 5 falls. In the first stage, negative binomial regression models for every cohort were fit. In the second stage, the resulting coefficient estimates were used to derive overall coefficients with a random effect meta-analysis. Additionally, external model validation was performed by applying the three data sets to the models derived in the first stage, as well as the newly derived model in the second stage.Results: In total, 1855 community-dwelling older adults were included in the analysis (226 male, 1629 female; mean age 74 years). 1810 prior falls and 1565 incident falls were reported. The coefficients for the prior fall number were consistent among the three studies (Figure 1). Higgin's I2 was used as a measure for heterogeneity, ranging from 0 to 55.39%. The overall coefficient estimates derived from the meta-analysis indicated that the expected fall rate increases with the increasing number of previous falls. External model validation revealed that the prediction errors for the three data sets were independent of the model it was applied to (e.g., GERICO dataset applied to 1) GERICO model: 0.82; 2) SCT model: 0.82; KFPS model: 0.81; overall model: 0.81).Conclusion: This analysis introduces a meta-analysed and externally validated fall rate prediction model for community-dwelling older adults. Thereby, the prior number of falls was shown to be a robust predictor for future falls among different cohorts.[1] Biver et al., RevMedSuisse, 2015. [2] Mittaz et al., BMC Geriatrics, 2019. [3] Vilpunaho et al., BMJ Open, 2019.

[8]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine & Division of Geriatrics, Geneva University Hospitals and Faculty of Medicine , Switzerland

BackgroundFalls remain the leading cause of fractures in older adults and may result from several intrinsic and extrinsic risk factors. Among them, the role of the global balance of the spine (since recently easily evaluated with the advent of EOS® technology) has never been fully established. In the SAFE cohort, we aimed to determine the association between global balance of the spine, physical function and falls in community-dwelling older adults. MethodsSAFE is an ongoing prospective 3-year longitudinal cohort study conducted in Geneva (Switzerland) among community-dwelling adults aged >=65 years without history of instrumented spinal surgery. All subjects undergo at baseline and 3-year a comprehensive assessment battery including: full skeleton 2D/3D radiographs in the standing position by EOS® low-dose biplane X-ray imaging system, DXA imaging, and physical function tests. Prospective falls and fractures are also collected over the 3-year. Spino-pelvic parameters measured include, among others, the spino-sacral angle (SSA) and the C7-central sacral line (C7-CSL) distance for sagittal and coronal balance, respectively.ResultsAmong the 110 subjects (mean age, 75 years; 76% female) included in the final cross-sectional analysis, 40 (36%) reported one or more falls in the past 12 months, 19 (17%) had a Short Physical Performance Battery (SPPB) score <=9 and 8 (7%) were sarcopenic. Global sagittal balance was independently associated with physical performances after controlling for potential confounders (adjusted regression coefficient SPPB/SSA= 0.04, 95%CI [0.01-0.08]; p=0.024). Global coronal balance was independently associated with both 1-year retrospective falls (OR C7-CSL/faller=1.59, 95%CI [1.10-2.30]; p=0.015) and 3-year incident falls (n=66 first subjects in the longitudinal analysis; OR C7-CSL/faller=2.23, 95%CI [1.23-4.03]; p=0.008 and IRR C7-CSL/number of falls=1.55, 95%CI [1.21-1.98]; p=0.001), after controlling for potential confounders including age, sex, comorbidities, vertebral fractures and physical performances by SPPB score.ConclusionsOur results suggest that global sagittal balance of the spine is an independent contributor to physical impairments, while global coronal balance is an independent predictor of incident falls in older adults. Further ongoing longitudinal analysis will fully reveal whether global balance of the spine relates to fractures and the role of compensating mechanisms.

Association of circulating sclerostin level with frailty in Korean older adults *Seong Hee Ahn[1], Hee-Won Jung[2], Eunju Lee[2], Ji Yeon Baek[2], Il-Young Jang[2], So Jeong Park[3], Jin Young Lee[3], Eunah Choi[3], Yun Sun Lee[3], Beom-Jun Kim[4], Seongbin Hong[1]. [1]Department of Endocrinology and Metabolism, Inha University Hospital, Inha University School of Medicine, Republic of Korea. [2]Division of Geriatrics, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Republic of Korea. [3]Asan Institute for Life Sciences, Asan Medical Center, Republic of Korea. [4]Department of Endocrinology and Metabolism, Asan Medical Center, University of Ulsan College of Medicine, Republic of Korea

Background: Sclerostin has recently been recognized not only as an osteokine, but also as a myokine that plays an essential role in bone and muscle crosstalk. Although both osteoporosis and sarcopenia are closely related to aging, the relationship between circulating sclerostin and frailty reflecting on biological age has never been investigated. Therefore, we evaluated the association of serum sclerostin levels with frailty and its related parameters in a cohort of ambulatory, community-dwelling Korean older adults.Methods: Blood samples were collected from 247 participants who underwent a comprehensive geriatric assessment, and serum sclerostin level was measured using an enzyme-linked immunosorbent assay. Phenotypic frailty and deficit accumulation frailty index were assessed using widely validated approaches, proposed by Fried and Rockwood groups, respectively.Results: After adjusting for sex, age, and body mass index, the frail participants presented 35.5% and 33.3% higher serum sclerostin levels than those with robustness and prefrailty, respectively (both P < 0.001). Consistently, circulating sclerostin level was positively related to frailty index (? =

0.205, P = 0.001), and the odds ratio (OR) per standard deviation increment of serum sclerostin level for phenotypic frailty was 1.87 (P = 0.003). Furthermore, compared with those in the lowest serum sclerostin quartile, the participants with the highest quartile had 38.5% higher frailty index (P = 0.026) and 9.91-fold higher risk for phenotypic frailty (P = 0.039). Conclusions: These data provide clinical evidence that circulating sclerostin level might be a potential biomarker for assessing the risk of frailty in humans.

Successful Pancreas-Kidney Transplantation Recipients Need Better Care for Osteoporosis *Yohei Asada[1], Yasumasa Yoshino[1], Hiroaki Sumioki[1], Yuka Nakajima[1], Sayumi Kanie[1], Izumi Hiratsuka[1], Megumi Shibata[1], Takeshi Takayanagi[1], Yusuke Seino[1], Atsushi Suzuki[1]. [1]Fujita Health University, Japan

Purpose:Simultaneous pancreas-kidney transplantation (SPK) could eliminate both insulin injections and maintenance dialysis and also improve life expectancy in type 1 diabetes (T1DM) patients with kidney failure. Recent advances in immunosuppressive therapy have improved the engraftment rate for pancreas transplantation (PTx). At the same time, long-term immunosuppressive medications could cause a decrease of bone mineral density (BMD), leading to an increased risk of fracture. The aim of this study is to evaluate the bone turn over and bone mass in successful post-PTx recipients.Methods: T1DM patients (n=34, M/F=11/23, age 46.7 +/-8.7 years old) who underwent PTx from 2013 to 2021 were enrolled in this study. The breakdown was 28 SPK and 6 PTx after kidney transplantation (PTA). All patients were received prednisolone (4.9 +/- 0.5 mg/day) throughout the observation period. Lumbar spine (LS) and femoral neck (FN) BMD was examined at baseline, 1 and 2 years after PTx as well as bone turnover markers. Total FN 2D-DXA images were analyzed using 3D-SHAPERTM Software. There were 15 patients with anti-osteoporotic treatment; 9 with denosumab (Dmab group) and 7 with active vitamin D alone (Vit D group), whereas 18 patients were observed without treatment (Control group).Results: All patients had become insulin-free and free from hemodialysis. Their serum creatinine and creatinine clearance remained stable during study period. At the baseline, the average LS and FN BMD T-scores were -1.35 +/-0.97 and -2.04 +/-0.76, respectively, and 12 patients were categorized as osteoporosis. After 2 years, the percent change from baseline in LS BMD was -3.1%($p<0.05$) in control group, +0.6% in Dmab group, and +0.5% in Vit D group. Trabecular bone score was not significantly changed in all groups. FN areal BMD (aBMD), trabecular volumetric BMD (vBMD), cortical surface BMD (sBMD), cortical thickness (Cth) decreased in control group (-5.9%, -9.7%, -4.6%, -3.9%). In Dmab and Vit D groups, aBMD, vBMD, sBMD and Cth were not changed. There was a significant decrease in serum BAP and TRACP-5b in the Dmab group at 1year after PTx and serum BAP decreased in Vit D group.Conclusion: Bone structure would deteriorate after PTx without treatment, and the recipients should be monitored for bone health regularly, and if necessary, receive appropriate interventions.

Bone remodelling and responsiveness to mechanical stimuli in type 1 diabetes mellitus: the role of neuropathy *Matthias Walle[1], Ankita Duseja[2], Danielle Whittier[3], Tatiane Vilaca[4], Margaret Paggiosi[5], Richard Eastell[4], Ralph Müller[3], Caitlyn Collins[3]. [1]ETH Zurich, . [2]Department of Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom. [3]Institute for Biomechanics, ETH Zurich, Zurich, Switzerland, Switzerland. [4]University of Sheffield, United Kingdom. [5]Department of Oncology and Metabolism, University of Sheffield, Sheffield, UK, United Kingdom

Type 1 diabetes mellitus (T1DM) has been linked to increased osteocyte apoptosis, local accumulation of mineralised lacunar spaces and microdamage suggesting an impairment of the mechanoregulation network in affected individuals. Diabetic neuropathy might exacerbate this dysfunction through direct effects on bone turnover, and indirect effects on balance, muscle strength, and gait. However, the in vivo effects of impaired bone mechanoregulation on bone remodelling in humans remain underexplored. Based on previous ex vivo studies we hypothesised that individuals with T1DM would demonstrate impaired bone turnover and mechanoregulation.We assessed consenting participants with T1DM without (n=6) and with distal symmetric sensorimotor polyneuropathy (T1DM+, n=14) and controls (n=9) at baseline and 4-year follow-up. We tested nerve conduction in participants with T1DM using DPNCheck (Neurometrix). We used longitudinal high-resolution peripheral quantitative computed tomography (XtremeCT, Scanco Medical AG, 82 ?m) at the standard distal sites to assess bone turnover. We used 3D rigid image registration to identify local trabecular bone formation (Tb.F) and resorption (Tb.R) sites and quantified mechanical stimuli at these sites using micro-finite element analysis (Fig 1A-C). We calculated odds ratios to determine the likelihood of bone formation (ORF) and resorption (ORR) with increasing/decreasing strain in percent as markers for mechanoregulation.At the distal radius, Tb.F was 26% reduced in T1DM (p=0.56) and 56% in T1DM+ ($p<0.05$, Fig. 1D) compared to controls. Tb.F correlated positively with nerve conduction amplitude ($r=0.74$, $p<0.05$, Fig. 1E) in participants with T1DM and negatively with glycated haemoglobin (HbA1c) ($r=-0.45$, $p<0.05$). Additionally, ORF was 30% reduced in T1DM compared to controls, regardless of neuropathy status (p0.65).Our findings represent in vivo evidence suggesting that bone formation in individuals with T1DM is in a state of low responsiveness to mechanical stimuli, resulting in impaired bone formation rates; these relate to the degree of neuropathy and level of diabetes control. Adverse effects were more severe at the radius than the tibia, possibly resulting from differences in site-specific mechanical loading. These findings could have implications for understanding the alterations in bone quality in T1DM.

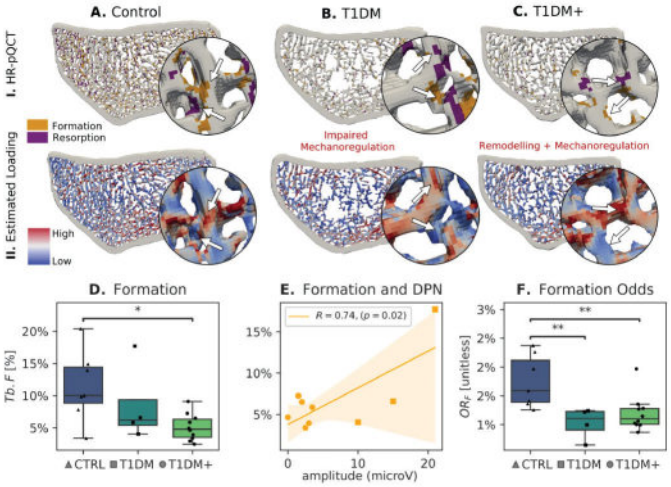

Fig. 1: (I) Distal radius cross-sections (10 slices) showing bone formation and resorption in (A) controls, (B) T1DM, and (C) T1DM+ participants. (II) Local mechanical loading estimates. (D) Bone formation and (E) correlation with P1NP. (F) Mechanoregulation of bone formation sites (* p<0.05, ** p<0.01).

Effect of microvascular disease on bone blood flow regulation in older adults with Type 1 Diabetes: preliminary findings *ADINA DRAGHICI[1], Elaine Yu[2], Mary Bouxsein[3], J. Andrew Taylor[4, 1], United States. [2]Massachusetts General Hospital, United States. [3]Beth Israel Deaconess Medical Center, Harvard Medical School, United States. [4]Physical Medicine and Rehabilitation, Harvard Medical School, Schoen Adams Research Institute at Spaulding Rehabilitation , United States

Skeletal fragility is an important complication of Type 1 Diabetes (T1D), particularly among older adults. Microvascular disease (MVD), one of the most serious consequences of diabetes, has been linked to worse bone health in T1D, suggesting a potential direct pathophysiologic link between vascular disease and bone deficits. However, altered vascular control in bone remains unexamined. These preliminary data derive from our investigation of a key vascular mechanism for blood flow regulation in bone - myogenic vasoconstriction. Our recent data in young healthy adults has shown for the first time that myogenic vasoconstriction is an active regulator of blood flow in bone, but this mechanism has yet to be explored in T1D.In older adults with T1D (N=10, 63+/-2yrs), we characterized myogenic vasoconstriction in the tibia via custom-made near infrared spectroscopy (total hemoglobin, tHb) and in the whole leg (reflective primarily of muscle) via Doppler ultrasound. Results were compared to data in young healthy adults (N=13, 26+/-4 yrs). We employed leg dependency (lowering the leg below heart level) to increase arterial transmural pressure and engage myogenic vasoconstriction. Responses were assessed during 5min supine, 5min seated with legs extended (Level 1), and 5min seated with 90deg knee flexion (Level 2). In those with T1D, increased perfusion pressure at both levels (?23+/-2 and ?33+/-1mmHg; $p<0.01$) was accompanied by proportional declines in whole leg blood flow (?-6.14+/-2.24 and ?-10.4+/-1.90cm/s; $p<0.01$), indicating myogenic vasoconstriction of a similar magnitude in young adults. Tibial tHb decreased proportionally as well (?-3.40+/-2.79 and ?-6.14+/-2.24?M; $p<0.05$), indicating vasoconstriction in the tibial vasculature; however, this response was up to 5X greater than in young adults. Interestingly, those with T1D and MVD (N=5) had a strong tendency for greater tibial vasoconstriction at both levels compared to those with no MVD (N=5) (Level 1: ?-7.02+/-2.83 vs 0.23+/-4.71?M, p=0.1; Level 2: ?-10.6+/-2.46 vs -3.66+/-3.66?M; p=0.08) despite similar vasoconstriction in the whole leg. There were no age differences between T1D groups. Hence, older adults with T1D have compromised bone blood flow that appears to be worse in those with MVD. These preliminary results represent the first direct assessment of bone blood flow in older adults with T1D providing a strong foundation for the potential mechanistic link between MVD and diabetes-induced bone loss.

Validation of Maturity Prediction for Children and Adolescents with Type 1 Diabetes *Zahra Ghafouri[1], James (J.D.) Johnston[2], Munier Nour[3], Saija Kontulainen[1]. [1]College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada, Canada. [2]College of Engineering, University of Saskatchewan, Saskatoon, SK, Canada, Canada. [3]College of Medicine, University of Saskatchewan, Saskatoon, SK, Canada , Canada

Introduction: At the same chronological age, the range in somatic maturity can be large, particularly around the adolescent growth spurt. Thus, validated estimates of somatic maturity are essential in clinical research when assessing skeletal growth and development. Predictive equations, based on predicting years from peak height velocity (i.e., maturity offset, MO) have been validated for typically developing children and adolescents. The predictive accuracy of these equations has not been assessed in children and adolescents with type 1 diabetes (T1D). Validation is needed, as sex-specific impairments in growth velocity during the pubertal growth spurt have been reported in adolescents with T1D, which may affect predictive accuracy. The objective of this study is to assess agreement and differences between predicted and observed MO in female and male children and adolescents with T1D. Methods: We obtained prospective measures of height from health records of participants in the Bone Strength Development Study in Children with T1D (BSDS). We applied the Preece-Baines Model and defined age at peak height velocity (APHV) for 22 participants (12 females and 10 males). We calculated observed MO by subtracting age at each measurement from APHV for male (Nobservations = 109, age 6-18 years) and female (Nobservations = 144, age 3-17 years) participants. We used Moore et al. maturity prediction equations to predict MO at each measurement time. We used sex-specific linear regression models to report model-fit (R2) for the agreement and paired t-tests to report mean differences (?) with 95% confidence intervals, between observed and predicted MO. Significance was set to p <0.05.Results: Predicted MO explained 86% and 87% of the variance in the observed MO in male and female participants, respectively. Predicted and observed MO means did not differ significantly in male (? 0.18, 95% CI -0.02 to 0.38) nor female (? 0.09, 95% CI -0.06 to 0.25) participants.Conclusion: The maturity prediction equation estimated MO within 2 months from the observed offset in both female and male children with T1D. These findings warrant cross-validation in a larger sample of children with T1D. Nevertheless, initial findings suggest that the commonly used Moore et al. equation may offer a reliable and practical solution to estimate biological maturity in studies assessing growth and development in children and adolescents with T1D.

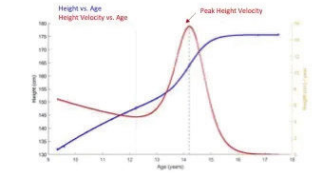

Fig 1. Example of Preece-Baines model to estimate age at peak height velocity (APHV) for a male participant

Chronic kidney disease is associated with lower cortical measures at proximal femur as assessed by 3D-DXA *M. Kužma[1], Z. Kužmová[1], L. Humbert[2], M. Lopez Picazo[2], J. Falat[1], J. Smaha[0], P. Jackuliak[1], Z. Killinger[0], J. Payer[1]. [1]5th department of Internal Medicine, Comenius University Faculty of Medicine, University Hospital , Bratislava, Slovakia, Slovakia. [2]3D-Shaper Medical, Barcelona, Spain, Spain. [0]5th department of Internal Medicine, Comenius University Faculty of Medicine, University Hospital , Bratislava, Slovakia, Slovakia

Introduction: Patients with chronic kidney disease (CKD) has 2-14 fold increase in fracture risk, especially in later stages of the CKD. The gold standard for the diagnosis of osteoporosis represents DXA, but its use is limited due to lack of possibility to measure trabecular and cortical characteristics and interference of aortic calcifications with BMD. Specific information about bone microstructure and turnover could be obtained by bone biopsy, but this is limited due to invasiveness.Aim: To compare several non-invasive DXA-derived methods used for assessment trabecular and cortical parameters, such a s trabecular bone score (TBS), 3D-Shaper and hip structure analysis (HSA) in subjects across all CKD stages.Patients and methods: In total, 89 CKD (38 females / 51 males; mean age 69,5 years) subjects were included in the analysis. According to glomerular filtration rate (GFR) there were 12; 23; 10; 14; 14 and 16 subjects in stage G1, G2, G3a, G3b, G4 and G5, respectively. BMD at lumbar spine (LS) and proximal femur (hip and neck) was analyzed by Hologic Horizon device. LS TBS was analyzed by TBS Insight software. Proximal femur parameters such as cortical and trabecular volumetric (v) BMD, cortical thickness (CTh) and surface (s) BMD and HSA parameters such as buckling ratio (BR), cross-sectional area (CSA) and section modulus (Z) were analyzed by 3D-Shaper-research v. 2.12.1. In all subjects bone turnover markers such as CTx, P1NP and Osteocalcin was measured.Results: Cross-sectional comparison between each CKD stage showed gradually decreasing LS BMD, cortical vBMD (neck and TH), TH Cth and neck BR starting from G3b, G4 and G5 stages; but not in earlier stages of CKD (G1-G3a). Comparison of means between earlier stages (G1-G3a) versus later stages (G3b-G5) of CKD showed significant differences in CTx (386 vs. 1053 ng/l); TH aBMD (0,991 vs 0,859 g/cm2), cortical vBMD at TH (831 vs 795 mg/cm3) and neck (837 vs.788 mg/cm3), TH cortical sBMD (170 mg/cm2) and TH Cth (2,03 vs 1,92 mm) (all p<0.05). Among all subjects, strong positive associations between GFR and cortical parameters (neck/TH vBMD and TH Cth) were observed (p<0.01).Conclusion: This study showed that later stages of CKD (G3b - G5) CKD have lower cortical bone parameters, such as vBMD, sBMD and CTh, as assessed by 3D Shaper. In addition, most of the cortical parameters are associated with GFR, showing direct relationship of kidney function and bone. These results agree with the previous findings provided by bone histomorphometry. As such, it is likely that 3D Shaper as non-invasive DXA derived method can be of use in assessment of fracture risk in CKD subjects especially in later stages of the disease. However, further prospective studies with greater amount of subjects and fracture data are needed.

Role of Selcopintide in Alleviating the Progression of Diabetic Periodontitis *Jihyun Hong[1], Joo-Cheol Park[1]. [1]Seoul National University, Republic of Korea

Diabetes mellitus (DM) is a systemic metabolic disorder characterized by hyperglycemia which can lead to various complications, including periodontitis. Periodontitis is a chronic inflammatory disease that affects the supporting tissues of the teeth, including the periodontal ligament (PDL), cementum, alveolar bone, and gingiva. Hyperglycemia can lead to oxidative stress and inflammation, which can exacerbate periodontitis by affecting the host response to bacterial pathogens. Mitochondria are the primary source of ROS, and their dysfunction can contribute to the development and progression of diabetic periodontitis. Therefore, regulating mitochondrial function and suppressing the production of pro-inflammatory cytokines are important to alleviate the progression of diabetic periodontitis. Copines are a family of ubiquitous Ca2+ -dependent, phospholipid-binding proteins. Our previous studies have demonstrated that Selcopintide (SCPT), CPNE7-derived peptide, can promote the regeneration of the PDL and enhance the attachment activity of human periodontal ligament cells (hPDLCs). Furthermore, CPNE7 has been shown to be involved in DNA damage repair by removing ROS on human dental pulp cells. It suggests that CPNE7 may be a potential therapeutic target for the treatment of diabetic periodontitis. Therefore, this study aimed to explore the effect and mechanism of SCPT on the expression of inflammatory cytokines and oxidative stress in the development of diabetes mellitus-periodontitis, as well as potential therapeutic strategies. In vitro, hPDLCs were stimulated by high glucose (35mM) and LPS to reflect the high glucose status and the infection of periodontitis causative bacteria. mRNA expressions of inflammatory cytokines were quantified, and reactive oxygen species was measured. The protein expression level of mitochondrial function-related markers in the cells were also detected by Western blot. Our study demonstrates that the expression of inflammatory cytokines increased when the cells were stimulated by both high glucose and LPS compared to when they were stimulated by only control or LPS. However, when treated with SCPT, this effect was alleviated. Reactive oxygen species of the cells with treated both of high glucose and LPS was also reduced after treating SCPT with the upregulation of mitochondrial functions. In conclusion, SCPT can alleviate the progression of diabetic periodontitis by regulating oxidative stress and its anti-inflammatory effects.

Evaluation of PTH-Ca Axis in Normocalcemic Primary Hyperparathyroidism
*Reiko Inoue[1], Fukuo Kosokabe[1], Kota Ishizawa[1], Yoshiyuki Ban[1], Daisuke Inoue[1]
[1]Teikyo University Chiba Medical Center, Japan

Background & Aim: Normocalcemic primary hyperparathyroidism (NPHPT) is defined by normal serum calcium (Ca) and elevated PTH. Although vitamin D repletion is recommended upon diagnosis, differentiation between NPHPT and secondary hyperparathyroidism (SHPT) due to vitamin D deficiency is often difficult. And we do not know what proportion of subjects with normal Ca and high PTH are indeed diagnosed NPHPT in the real-world setting. The aim of the present study was to evaluate PTH-Ca axis and to explore clinical indicators differentiating between NPHPT and SHPT in possible PHPT cases with high intact PTH levels.Subject & Method: We screened 1,101 patients given ICD 10 codes of hyperparathyroidism at our hospital from January 2012 to September 2022 for possible NPHPT, excluding those under the age of 20, those with chronic kidney disease (eGFR<30), and those with other apparent hypercalcemic conditions (N=704). We further excluded 11 cases diagnosed and treated for PHPT at other hospitals. Of the remaining 386 cases, we identified 215 subjects with intact PTH levels above 50 pg/ml for further analysis.Result: Of the 215 cases analyzed, 70 had PHPT with apparent hypercalcemia, and the remaining 145 were suspected to have NPHPT or SHPT. Of these, 17 cases were subsequently diagnosed with PHPT, including 10 MIBI-positive cases and 7 cases developing overt hypercalcemia after vitamin D supplementation. Among the remaining 128 cases, 74 had their 25(OH)D levels measured: among them 19 had probable NPHPT based on 25(OH)D >20 ng/ml (with or without vitamin D supplementation) and intact PTH >65 pg/ml, 34 had possible NPHPT based on intact PTH levels of 50-65 pg/ml, and 21 had vitamin D-deficient SHPT whose PTH normalized after vitamin D supplementation. In the probable NPHPT group (N=19), the pre-supplementation levels of Ca, PTH and 25(OH)D were 9.5+/-0.5 mg/dl, 85.8+/-31.6 pg/ml, and 21.5+/-7.2 ng/ml, respectively. There was no difference in bone parameters including BMD and TBS between the NPHPT and SHPT groups, but the product of intact PTH and Ca values was significantly higher than SHPT in the NPHPT group.Conclusion: 25(OH)D >20 ng/ml and intact PTH >65 pg/ml may be indicative of NPHPT. Further observation of the natural course and reassessment after achieving complete sufficiency with 25(OH)D >30 ng/ml will be necessary.

Association of Sodium-Glucose Cotransporter 2 Inhibitor Use With Risk of Osteoporotic Fracture Among Older Women: A Nationwide, Population-Based Cohort Study
*Seunghyun Lee[1], Min Heui Yu[2], Namki Hong[3], KYOUNG JIN KIM[4], Hae Kyung Kim[5], Yumie Rhee[6], Minyoung Lee[5], Kyoung Min Kim[7]
[1]Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, [2]SENTINEL team, Division of Endocrinology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of Korea, [3]Division of Endocrinology, Republic of Korea, [4]Korea University College of Medicine, Republic of Korea, [5]Institute of Endocrine Research, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of Korea, [6]Yonsei University College of Medicine, Republic of Korea, [7]Yongin Severance Hospital, Yonsei University College of Medicine, Republic of Korea

Sodium-glucose cotransporter-2 inhibitor (SGLT2i) is a widely recommended anti-diabetic medication (ADM) due to its cardioprotective and renoprotective benefits. However, the effects of SGLT2i on fracture risk have been debated. The Canagliflozin Cardiovascular Assessment Study showed that SGLT2i increased hip fracture risk during the mean 6-year follow-up period. However, in most other large randomized controlled trials of SGLT2i, SGLT2i use was not associated with increased fracture risk. Although the fracture risk associated with SGTL2i use is controversial, there are concerns regarding fracture risk due to the increased risk of falls caused by volume depletion or disturbance of calcium phosphate balance. Therefore, in the present study, the association between SGLT2i use and fracture risk in elderly women (>= 65 years of age) who were newly prescribed ADMs was investigated using a national cohort database.?We used the data for this population-based cohort study obtained from the National Health Insurance Service of Korea between January 1, 2013, and December 31, 2020. Women older than 65 years old diagnosed with type 2 diabetes mellitus who were newly prescribed ADMs other than glucagon-like peptide-1 receptor agonists and thiazolidinedione and who had available comprehensive health check-up data were included.A total of 1,333 SGLT2i users was analyzed and compared with covariate (e.g., body mass index (BMI), age-matched non-SGLT2i users at a 1:2 ratio (n = 2,626). After propensity score matching, mean age (70.3 years vs. 70.3 years, p = 0.830), BMI (27.4 kg/m2 vs. 27.4 kg/m2, p = 0.924), number of oral ADMs (1.4 vs. 1.3, p = 0.092), and other covariates were well-balanced between SGLT2i users and non-SGLT2i users. During the follow-up period, SGLT2i use was associated with a significantly increased risk of vertebral fracture compared with non-SGLT2i use (incidence rate 19.2 vs. 13.8 per 1,000 person-years; hazard ratio 1.40, 95% confidence interval 1.00-1.96, p = 0.049). Regarding the risk of other types of fracture, any fractures, hip fractures, and non-hip or non-vertebral fractures, significant differences were not observed between SGLT2i users and non-SGLT2i users.In conclusion, SGLT2i use showed a 40% higher risk of vertebral fracture than non-SGLT2i use in elderly women. Although further validation is required, SGLT2i should be cautiously prescribed in older women due to the potential association with fracture risk in this vulnerable population.

Hypothyroidism and Future Fracture Risk Prediction From a Prospective Outpatient Fracture Liaison Service
*Brittany Carde[1], Leah Kennedy[1], Sarah Hamilton[1], Stephanie Yee[1], Kim Rondeau[1], Jacques van der Merwe[1], Emma Billington[1], Prism Schneider[1]
[1]University of Calgary, Canada

Background: There are conflicting reports in the literature regarding the relationship between hypothyroidism and fragility fracture (FF) risk. Some reports suggest a significantly prolonged bone remodeling cycle in patients with hypothyroidism and increased bone mass. These result in increased bone stiffness, thus equating to increased FF risk. This study aimed to compare FF risk between those with and those without a pre-existing diagnosis of hypothyroidism at the time of initial FF presentation.Methods: In August 2020, we introduced a 3i OFLS at a single Level 1 trauma centre. Active case finding was used to identify patients over the age of 50 with a new FF to their wrist, shoulder, or pelvis. Following informed consent, enrolled patients met with the OFLS nurse at their initial fracture assessment and underwent a complete bone health history, including hypothyroidism assessment. Thyroid-stimulating hormone levels, future fracture risk using the Fracture Risk Assessment Tool (FRAX), and bone mineral density (BMD) were captured. T-tests and Chi square analyses were used to compare age, sex, and FF type between those with and without hypothyroidism and a Wilcoxon rank sum test was used to compare FRAX with and without BMD between these two groups.Results: Within the first 12-months, 128 patients with a new FF were enrolled, with 26 (25.5%) having a pre-injury diagnosis of hypothyroidism. There was no difference in the mean age between groups (mean age= 68 [+/- 8] years for those with hypothyroidism and 65 [+/- 11] years without; p =0.11), but there were significantly more females in the hypothyroidism group (100% vs. 84%; p=0.04). The majority of participants had suffered a distal radius fracture (58% in the hypothyroidism group and 60% in those without hypothyroidism). When factoring in BMD, significantly higher FRAX scores were observed in the hypothyroidism group (mean FRAX=19 [+/- 9]) compared to those without hypothyroidism (mean FRAX=16 [+/- 10]; p=0.04). However, when excluding BMD in FRAX calculations, there was no difference between the groups.Conclusions: The results of this study support the discordance in the literature around use of BMD in fracture risk prediction in patients with pre-fragility fracture diagnosis and treatment. Interpretation of fracture risk in the setting of hypothyroidism warrants further investigation for accurate prediction of future fracture risk and decision-making around indications for initiation of osteoporosis pharmacotherapy.

The Association between Intrahepatic Lipid Content and Bone Microarchitecture and Strength (Assessed by HR-pQCT): The Maastricht Study.
*VEERLE VAN HULTEN[1], Johanna Driessen[2], Marleen van Greevenbroek[3], Carla van der Kallen[3], Annemarie Koster[4], Martijn Brouwers[3], Eline Kooi[5], Pieter Dagnelie[6], Coen Stehouwer[3], Joop Van Den Bergh[7]
[1]Maastricht University, [2], Netherlands, [3]Department of Internal Medicine, MUMC+, Netherlands, [4]Department of Social Medicine, Maastricht University, Netherlands, [5]Department of Radiology, MUMC+, Netherlands, [6]School for Cardiovascular Diseases, Maastricht Universiity, Netherlands, [7]VieCuri MC Noord-Limburg and Maastricht UMC,

Background: It is known that type 2 diabetes (T2D) is associated with a number of comorbidities, such as an increased fracture risk, possibly due to impaired bone quality. T2D has also been associated with non-alcoholic fatty liver disease (NAFLD) characterized by a high intrahepatic lipid (IHL) content. In turn, NAFLD has been shown to be a risk factor for osteoporotic fractures.Purpose: To determine the association of IHL content with parameters of bone microarchitecture and strength assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT).Methods: This study includes cross-sectional data from 2104 participants of the Maastricht Study who underwent a HR-pQCT scan (first generation) at the distal radius. MRI was performed to determine IHL content, expressed as the percentage of hepatic triglyceride content in the total liver volume. Multiple linear regression models were used to investigate the association of IHL content with HR-pQCT parameters of bone microarchitecture and strength. Analyses were stratified by sex due to inherent differences in bone metabolism, and were adjusted for glucose metabolism status, age, comorbidities, medication and lifestyle factors.Preliminary Results: We included 1057 men and 1047 women. Male participants were on average 60 (+/-8.7) years old, and female participants were on average 58 (+/-8.8) years old. After adjustment, IHL content was positively associated with total bone mineral density (BMD) and cortical BMD in the distal radius in men and women, and with trabecular BMD, cortical area, stiffness, and failure load in women (Table 1). When BMI was added to the linear regression model, all significant associations between IHL content and HR-pQCT parameters were strongly attenuated and not statistically significant.Conclusion: These findings suggest that bone quality may not be impaired in individuals with an increased IHL content, and that bone strength may even be greater in women with NAFLD. However, it is possible that this finding is at least partially

due to the association of BMI with IHL content and with bone density, stiffness and failure load, since no statistically significant associations between IHL content and HR-pQCT parameters remained when BMI was added to the linear regression model.

Table 1: The association between IHL content and bone architecture and bone strength in the distal radius (assessed by HRpQCT)

Effects of Melatonin Supplement on Bone Mineral Density in Thalassemia Patients with Iron Overload and Low Bone Mineral Density: A Randomized Controlled Study *Pokpong Piriyakhuntorn[1], Adisak Tantiworawit[1], Mattabhorn Phimphilai[2], Tawika Kaewchur[3], Piangrawee Niprapan[1], Nattayaporn Apaijai[4], Krekwit Shinlapawittayatorn[4], Nipon Chattipakorn[4], Siriporn C. Chattipakorn[4]. [1]Division of Hematology, Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Thailand. [2]Division of Endocrinology, Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Thailand. [3]Division of Nuclear Medicine, Department of Radiology, Faculty of Medicine, Chiang Mai University, Thailand. [4]Cardiac Electrophysiology Research and Training Center, Faculty of Medicine, Chiang Mai University, Thailand

Background: Low bone mineral density (BMD) is commonly found in thalassemia patients, leading to increased incidence of bone fracture. It is known that iron-overloaded condition in thalassemia patients increased circulating oxidative stress, which resulted in decreased BMD. Melatonin is a powerful antioxidant. It improves bone quality in postmenopausal osteopenia. However, the effect of melatonin on bone in thalassemia patients with iron-overloaded and low BMD conditions has not been investigated.Aim: To investigate the effect of melatonin supplementation on bone health in thalassemia with iron- overloaded and low BMD conditions.Methods: We conducted a randomized controlled study at CMU Outpatient Hematology Clinic. Thalassemia patients who had a Z-score of BMD at L-spine, femoral neck, or total hip of less than -2.0, indicating low BMD, and serum ferritin level of more than 500 ?g/L, characterized as iron overload, were recruited in the study. 30 patients were allocated to orally receive either melatonin 20 mg/day or placebo at bedtime for 12 months. BMD in each patient was re-evaluated at 12 months. Bone turnover markers (BTM), malondialdehyde (MDA as an oxidative stress marker), and back pain score were assessed at baseline, 6, and 12 months. The outcome was the alterations of BMD at various sites as well as changes in serum BTM, MDA, and back pain score.Results: Thirty patients were enrolled in the study. Twelve patients were male. The mean age was 31.1+/-5.7 years old. Twenty-eight patients were identified as beta-thalassemia, and 25 were patients with transfusion dependence. At 12 months after interventions, we found that patients in both groups had no significant change in BMD at L-spine, femoral neck, or total hip, when compared to their baseline (Figure 1A). No significant change of serum CTX, P1NP, or SOST in both groups were found at 6-, 12-months. There was a significant reduction of serum MDA between groups at 6 and 12 months (Figure 1B). Back pain was significantly reduced at 12 months in only melatonin group. Melatonin significantly improved BMD at L-spine in males (Figure 1C) and patients with splenectomy (Figure 1D).Conclusion: Melatonin 20 mg/day for 12 months did not improve BMD in iron-overloaded thalassemia with low BMD. However, melatonin significantly reduced circulating oxidative stress and back pain score in those patients. Surprisingly, we observed the improvement of BMD at L-spine in male and post-splenectomy subgroups.

Areal bone mineral density, trabecular bone score and 3D-DXA analysis of proximal femur in psoriatic disease *Eric Toussirot[1], Renaud Winzenrieth[2], Francois Aubin[3], daniel wendling[3], Charline Vauchy[4], Maxime Desmarets[4]. [1]INSERM CIC_1431, France. [2]GALGO, Spain. [3]CHU, France. [4]INSERM CIC, France

Objectives: To evaluate bone mineral density (BMD) and bone quality, with assessment of the cortical and trabecular compartments, in patients with psoriasis (PsO) alone or with psoriatic arthritis (PsA).Methods: Patients with PsA and patients with PsO alone were evaluated and compared to control subjects matched for age, sex and body mass index category. Areal BMD (aBMD) was determined for the lumbar spine, femoral neck, total hip and total body using dual-energy X-ray absorptiometry (DXA). Bone quality was evaluated by using trabecular bone score (TBS) at the lumbar spine, and by 3D DXA-based analysis (3D Shaper) for the proximal femur.Results: 196 subjects including 52 patients with PsA and 52 patients with PsO and their respective paired controls were analyzed. Patients with PsA had comparable aBMD, TBS and 3D DXA analysis parameters compared to their paired controls. After adjustment for confounders, patients with PsO alone were characterized by a higher aBMD at the left femur and higher cortical 3D DXA derived parameters (total hip cortical surface BMD and total hip cortical thickness) than their paired controls (Figure 1). TBS was decreased in PsO compared to their controls.Conclusion: Patients with PsA had normal bone mass and bone quality parameters. Patients with PsO were characterized by higher femoral neck bone density by DXA and cortical parameters by 3D DXA-based analysis, supporting no increased risk for hip fracture. Conversely, bone texture by TBS assessment was decreased in patients with PsO, which may be associated with impaired vertebral bone resistance.Figure 1: 3D spatial distribution of differences in the cortical bone between the patients with psoriasis (PsO) (left femur N = 52, right femur N= 52) and their paired controls. Increases in cortical sBMD, vBMD and thickness are presented in blue-green color while decreases are presented in yellow-red color. Results are given for the right and left hips. Each figure shows the anterior and posterior view of the proximal femur. Results illustrate differences in percentage between PsO and controls. DXA-based 3D parameters were higher in patients with PsO, especially for the left femur. Differences were significant for cortical parameters.

Type 2 Diabetes is Associated with Better Bone Microarchitecture, higher BMD, but Impaired Physical Function and Increased Risk of Incident Fracture in Older Swedish Women from the SUPERB study. *Lisa Johansson[1], Kristian Axelsson[2], Mattias Lorentzon[3], Henrik Litsne[4], Michail Zoulakis[5]. [1]Institute of medicine, , [2]Institute of Medicine, Sahlgrenska Academy, Gothenburg University, , [3]Sahlgrenska Academy, University of Gothenburg, Sweden, [4]Sahlgrenska Osteoporosis Centre,University of Gothenburg, , Sweden, [5]Sahlgrenska Osteoporosis Centre, Institute of Medicine,University of Gothenburg, Sweden

Several studies have shown that type 2 diabetes mellitus (T2DM) is associated with incident fracture, but it is not clear if the risk increase is due to impaired bone microarchitecture, low bone material strength index (BMSi) or poor physical function. The aim of this study was to determine if T2DM is associated with bone microarchitecture, BMSi, physical function, and risk of incident fracture in older Swedish women.In total, 3028 Swedish women, 75-80 years old were included in the prospective SUPERB study. At baseline, information on clinical risk factors (CRFs) was collected using questionnaires. Bone mineral density (BMD) was measured with dual-energy X-ray absorptiometry, bone microarchitecture with HR-pQCT (XtremeCT), and BMSi obtained using the Osteoprobe device (n=630). Physical function was assessed using timed up and go (TUG), one leg standing (OLS), grip strength, chair stand test and by measurements of gait speed. Data on incident fractures were retrieved from a regional x-ray archive.At baseline, the 294 women with T2DM were compared to women (n=2714) without diabetes. Women with T2DM had higher BMD at all sites (total hip 4.7%, femoral neck (FN) 3.9% and lumbar spine L1-L4 5.4%, all p<0.01) than women without. At the ultradistal tibia, T2DM women had a greater cortical area (7.3%, p<0.01) and density (1.2%, p=0.03), as well as higher trabecular bone volume fraction (8.6%, p<0.01). There was no difference in BMSi between groups (n=630; T2DM 77.8+/-8.1 vs. controls 78.1+/-7.3, p=0.81). Women with T2DM performed significantly worse on all physical function tests than their non-diabetic controls. For example, grips strength was 10.1% lower, gait speed 10.2% slower, and TUG time 13.1% (p<0.001 for all comparisons) slower in women with T2DM than in those without.During 7.3 (4.4, 8,4) years (median (IQR) of follow-up there were 1071 incident any fractures, 797 major osteoporotic fractures (MOF), and 232 hip fractures. In adjusted (for age, BMI, FRAX CRFs and FN BMD) Cox regression models T2DM was associated with an increased risk of any fracture (HR 95% CI 1.26 [1.04-1.53], but the associations with MOF (HR 1.16 [0.92-1.46]) or hip fracture (HR 1.31 [0.85-2.00]) did not reach statistical significance.In conclusion, older women with T2DM have considerably better bone microarchitecture, and no different BMSi, but substantially poorer physical function than nondiabetic women, which could be the principal reason for the increased fracture risk observed in T2DM women.

People Living with HIV Show High Bone Marrow Adiposity and Low Volumetric Bone Mineral Density at the Femoral Neck using Data-Driven Spatial Image Analysis Techniques *Julio Carballido-Gamio[1], Magdalena Posadzy[2], Po-Hung Wu[2], Katie Kenny[3], Isra Saeed[2], Thomas Link[2], Phyllis Tien[4], Roland Krug[2], Galateia Kazakia[2]. [1]University of Colorado Anschutz Medical Campus, United States, [2]University of California, San Francisco, United States, [3]University of California, Berkeley, United States, [4]University of California, San Francisco & Department of Veterans Affairs Medical Center, United States

People living with HIV (PLWH) have increased risk for osteoporosis and fractures. However, the pathophysiology of this comorbidity is not fully understood. Low areal and volumetric bone mineral density (aBMD and vBMD), poor bone microarchitecture, high bone marrow adiposity (BMA), and correlations of BMA with vBMD and bone microarchitecture have been reported in PLWH at the proximal femur. However, the spatial localization of these phenomena is largely unknown. The purpose of this work was to investigate if there are regions in the proximal femur manifesting stronger associations of BMA with vBMD - indicative of high bone deterioration - using data-driven image analysis techniques. Fifty-one PLWH and 51 age-matched seronegative controls (SNC) were recruited for this study. Using quantitative computed tomography (QCT) and magnetic resonance imaging (MRI), vBMD and BMA maps of the non-dominant proximal femur were generated. Using a framework like voxel-based morphometry (VBM), image registration was used to spatially normalized all parametric maps to a common template, enabling voxel-wise Spearman partial correlations of BMA with vBMD for each group. Partial correlations were adjusted for age, body-mass-index (BMI), sex, and bone shape (90% variance) and yielded maps of correlations and P-values for each group. P-value maps were corrected for multiple testing using false discovery rate (FDR).The FDR-corrected Spearman partial correlation maps of BMA with vBMD are shown in Figures 1 A-D where voxels with no significant correlations were rendered transparent. As expected, BMA and vBMD were negatively correlated in both groups. However, these correlations had distinct patterns between groups with stronger associations in the femoral head in SNC, and in the femoral neck in PLWH. These findings reflect the observed low vBMD and high BMA in the femoral neck of PLWH shown in Figures 1 E-F. However, maps in Figure 1 also show high BMA in the superior aspect of the femoral head in PLWH that is not accompanied by low vBMD at the same region.Using data-driven image analysis techniques we showed that in PLWH there is a synergistic phenomenon of high BMA and low vBMD in the femoral neck, probably predisposing them to an increased risk of fracture. Another important observation was the independent increase in BMA - with respect to vBMD - observed at the femoral head in PLWH suggesting that BMA might provide independent information from vBMD in assessments of bone fragility.

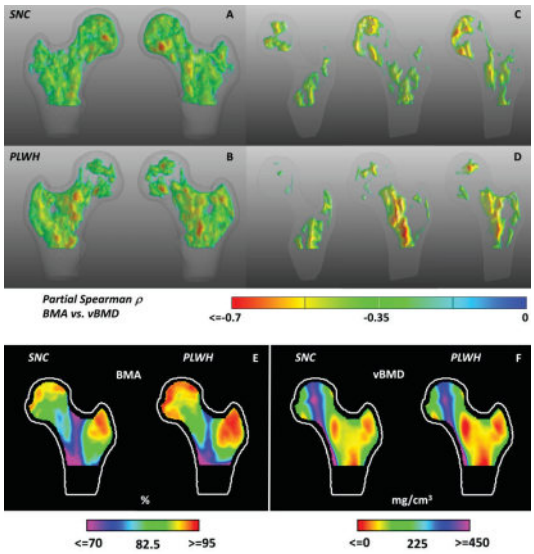

Figure 1. A-B Anterior and posterior views of three-dimensional renderings of FDR-corrected Spearman partial correlation maps of BMA with vBMD. **C-D** Posterior, central, and anterior cross-sections of A-B maps. **E-F** Central cross-sections of mean BMA and vBMD maps. Non-significant correlations in A-D were rendered transparent. The cortical bone was excluded from all analyses.

Correlates of MiR-144-3p With Bone Remodeling in Obese Patients With T1DM: Role of Aging And Thyroid Function *SOUAD DAAMOUCH[2], DAVID CARRO VAZQUEZ[2], Matthias Blüher[3], Lorenz Hofbauer[4], Matthias Hackl[5], Martina Rauner[6, 2], [, 2], Austria. [3]Department of Medicine and Clinic of Endocrinology and Nephrology, Germany. [4]TU Dresden University Medical Center, Germany. [5]TAMIRNA, Austria. [6]Medical Faculty of the TU Dresden, Germany

The incidence of type 1 diabetes mellitus (T1DM) is increasing worldwide. Studies have now revealed that obesity is present more often in these patients than previously thought. Furthermore, patients with T1DM are vulnerable to bone loss, however, the underlying causes are not fully understood. Previous studies have reported miR-144-3p to be upregulated in type 2 diabetes mellitus (T2DM) and to impair bone remodelling. Here, we hypothesized that miR-144-3p could play a role in diabetic bone disease associated with T1DM. We collected human serum samples (n=60 in total) from female and male patients with T1DM and non-diabetic individuals with an average age of 51 years. This cohort had an average BMI of 45 kg/m², reflecting severe obesity. Controls were matched according to age, sex, and BMI. Bone turnover markers including OCN and CTX were assessed using ELISA, and we collected clinical parameters such as HbA1c, cortisol, triglyceride, cholesterol, and thyroid-stimulating hormone (TSH) levels. miR-144-3p in the serum was measured by qPCR. As expected, a significant negative correlation was observed between HbA1c level and OCN in patients with T1DM ($r = 0.19$, $p=0.02$) compared to non-diabetic subjects. This difference was also observed in women only, who showed additional differences in CTX ($r = 0.36$, $p = 0,02$; $r = 0.38$, $p<0.02$), while men did not display any differences in bone turnover markers. Unexpectedly, circulating miR-144-3p was significantly downregulated (-37%, $p<0.05$) in patients with T1DM compared to healthy subjects. However, no significant associations were found for HbA1c, OCN, or CTX with miR-144-3p. Although no correlation with bone turnover markers was noted, a significant negative correlation between miR-144-3p and aging was observed in T1D men compared to healthy individuals ($r = 0.36$, $p<0.02$). This observation was associated with a low TSH level ($r = 0.85$, $p<0.003$), highlighting a potential thyroid disorder, which is a common secondary complication in T1DM patients. Additionally, TSH was also negatively correlated with aging in T1D patients compared to control subjects ($r = 0.90$, $p<0.0003$). Hence, this study identified miR-144-3p as a potential target for investigating the mechanisms underlying altered bone remodelling in T1DM, aging, and thyroid disorders. Further investigations are needed to validate miR-144-3p as a biomarker and to evaluate its role in bone remodelling.

Prediction of change in bone mineral density in patients with primary hyperparathyroidism after parathyroidectomy by using flotillin-1 extracellular vesicle-microRNAs *Seunghyun Lee[1], Sunyoung Park[2], Namki Hong[3], Yongnyun Kim[4], Jongju Jeong[5], Hogyeong Gwak[2], Hyo-Il Jung[2], Yumie Rhee[6]. [1]Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, [, 2]Department of Mechanical Engineering, Yonsei University, Republic of Korea. [3]Division of Endocrinology, Republic of Korea. [4]Yonsei University Health System, Republic of Korea. [5]Department of Surgery, Thyroid Cancer Clinic, Severance Hospital, Yonsei University College of Medicine, Republic of Korea. [6]Yonsei University College of Medicine, Republic of Korea

Primary hyperparathyroidism (PHPT) is characterized by hypercalcemia, increased parathyroid hormone (PTH) secretion, and higher fracture risk due to bone loss. While surgery can cure PHPT, only 30% of cases show improved bone mineral density (BMD) after surgery. Prior research has suggested potential BMD changes markers, such as PTH, and procollagen type 1 N-terminal propeptide (P1NP), but their validity is disputed. Accordingly, our team proposed circulating free miR-122-5p and miR-375 as predictive markers. However, due to increased stability of miRNAs in extracellular vesicle (EV), we propose an ExoBONE assay for a complementary assay of prediction of BMD using EV miRNAs, providing a more accurate marker..We consecutively enrolled patients who underwent parathyroidectomy for PHPT at Severance Hospital between July 2017 and June 2021, excluding those without a one-year post-surgery BMD, recent users of bone metabolism affecting medications, or those with insufficient specimens: 28 patients were included (specific EV group). Twelve healthy volunteers (control group) also participated. Osteoblast-derived EVs were isolated using microbeads coated with flotillin-1(FLOT-1) antibody. Sixteen miRNAs, which are related to osteoporotic fracture, were profiled from FLOT-1 EVs. 'BMD improvement' was defined by least significant change values, which were 3.32% for the lumbar spine, 5.82% for the femur neck, and 4.71% for the total hip.The specific EV group had a mean age of 54.1, with the control group at 29.3, and both were mostly women. Notable differences were seen in miRNA levels of miR-19b-3p, miR-21-5p, miR-93-5p, miR-124-3p, miR-148-3p, and miR-375 for FLOT-1 EV before and after surgery. Among them, preoperative miR-148-3p and miR-375 showed significant association with femur neck BMD improvement, even after adjusting for age, sex, PTH, and P1NP (miR-148-3p, odds ratio 0.67 [0.50-0.90], p=0.007; miR-375, odds ratio 1.00 [1.00-1.00], p=0.001). Due to the minimal odds ratio observed in miR-375, miR-148-3p was considered a better predictive marker.In conclusion, our study proposes miR-148-3p from FLOT-EVs as a marker to validate BMD improvement after surgery in patients with PHPT. ExoBONE assay could significantly enhance BMD monitoring, improve the identification of patients at higher risk of persistent bone loss post-surgery, and provide a potential tool for better understanding bone metabolism regulation.

Clustering HR-pQCT Parameters Reveals Three Clusters with Unique Density, Morphology, Microarchitecture & Mechanics in Older Men and Women: the Study of Muscle, Mobility and Aging (SOMMA) *Morgan Bolger[2], Kerri Freeland[2], Megan Marron[2], Nina Heilmann[2], Tong Yu[2], Lauren Roe[2], Nicole Sekel[2], Kristen Koltun[2], Katelyn Guerriere[3], Julie Hughes[4], Bradley Nindl[2], Ashley Weaver[5], Paolo Caserotti[6], Peggy Cawthon[7], Anne Newman[2], Jane A. Cauley[8], Elsa Strotmeyer[2]. [2]University of Pittsburgh, United States. [2]University of Pittsburgh, [, 3]USARIEM, United States. [4]US Army Research Institute of Environmental Medicine, United States. [5]Wake Forest University School of Medicine, United States. [6]University of Southern Denmark, Denmark. [7]California Pacific Medical Center, United States. [8]UNIVERSITY OF PITTSBURGH, United States

Age-related changes to bone density, morphology, and microarchitecture do not occur uniformly across the population and the common phenotypes beyond BMD are not well defined. We hypothesized that unsupervised clustering of high-resolution peripheral quantitative computed tomography (HR-pQCT) measures at the distal tibia (DT) and radius (DR) separately, would reveal unique skeletal phenotypes in the Study of Muscle, Mobility and Aging (SOMMA; year 1 visit), a cohort of community-dwelling older women and men (60% women; 87% white). HR-pQCT parameters at the DT (N=321; 76.3+/-4.7 years) and DR (N= 295; 76.1+/-4.5 years) were within-sex standardized as z-scores, then used to form clusters: density (Tt.BMD, Ct.BMD, Tb.BMD), geometry (Tt.Ar, Ct.Ar, Tb.Ar, Ct.Th), microarchitecture (Tb.Th, Tb.N, Tb.Sp), and bone length (Le). Fuzzy c-means clustering found 3 clusters, then discretized by the highest membership coefficient. DT cluster 1 (Figure 1; DTC1, n=121) had the highest Tt.BMD, Tb.BMD, Ct.Ar, Ct.Th, and Tb.Th. DT cluster 2 (DTC2, n=86) had the highest Tb.Sp and lowest Tb.BMD and Tb.N. DT cluster 3 (DTC3, n=114) had the highest Tt.Ar, Tb.Ar, and Le and lowest Tt.BMD, Ct.BMD, Ct.Ar, Ct.Th (all $p<0.05$). For DR, (DRC1, N=98; DRC2, N=103; DRC3, N=94) the same associations were seen for Tt.BMD, Tt.Ar, Ct.Ar, Tb.Ar, Ct.Th, and Le. The external bone size (Tt.Ar/Le) was higher in DTC3 (2.23+/-0.37) vs. DTC1 (1.95+/-0.30) and DTC2 (1.97+/-0.35). The estimated failure load (FL) was higher in DTC1 (11.1+/-3.1 kN) vs. DTC2 (9.1+/-2.7 kN) and DTC3 (8.9+/-3.0 kN, $p<0.05$ for all) with no difference in DTC2 vs. DTC3 ($p=0.58$). The cortical load fraction (Ct.LF) was highest in DTC2 (47+/-10%), followed by DTC1 (41+/-9%), and lowest in DTC3 (33+/-9%; all $p<0.05$), meaning DTC2 relied relatively more on the cortical and DTC3 on trabecular bone to achieve similar FL. For femoral neck (FN) DXA, FN BMD was lower in DTC2 (0.82+/-0.12 g/cm2) and DTC3 (0.84+/-0.12 g/cm2) vs. DTC1 (0.93+/-0.16 g/cm2), driven by higher FN area in DTC3 vs. DTC1 (5.41+/-0.54 vs. 5.18+/-0.54 cm2) and lower BMC in DTC2 vs. DTC1 (4.32+/-0.84 vs. 4.84+/-1.12 g). Similar associations in external bone size, FL, Ct.LF and FN measures were found for DR clusters. In summary, for both DT and DR sites, clusters with high-Tt.BMD, Ct.Ar, (C1), medium-Tt.BMD, Ct.Ar (C2), and low-Tt.BMD, Ct.Ar with high-Le and Tb.Ar (C3) were captured. Whether unique skeletal phenotypes differ in risk factors, muscle function, and fracture incidence need to be studied.

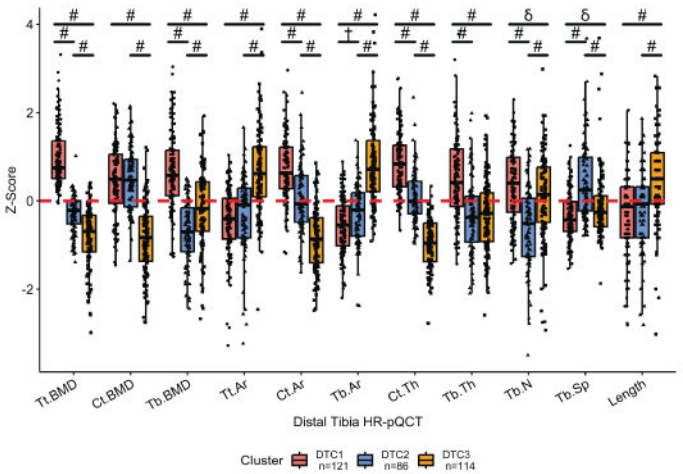

Figure 1: Box plots of standardized z-scores of HR-pQCT parameters for the distal tibia used to derive cluster assignments. Between groups pairwise Student's t-test or Wilcoxon test δ p<0.05, † p<0.01, ‡ p<0.001, # p<0.0001. *Abbreviations*: distal tibia cluster 1 (DTC1), distal tibia cluster 2 (DTC2), distal tibia cluster 3 (DTC3), total bone mineral density (Tt.BMD), cortical BMD (Ct.BMD), trabecular BMD (Tb.BMD), total area (Tt.Ar), cortical area (Ct.Ar), trabecular area (Tb.Ar), cortical thickness (Ct.Th), trabecular thickness (Tb.Th), trabecular number (Tb.N), trabecular spacing (Tb.Sp), and tibia length (Le).

Trabecular Bone Texture from Clinical MRI Scans Reflects Biomechanical Properties of Bone *Alexander Dash[1], Ryan Breighner[2], Fernando Quevedo Gonzalez[4], Matthew Koff[4], Olivia Blumberg[4], Alison Heilbronner[5], Emma Billings[6], Matthew Cunningham[4], Han Jo Kim[4], Jeri Nieves[7], Emily Stein[4]. [1]Icahn School of Medicine at Mount Sinai, , [2]Hospital for Special Surgery/Weill Cornell Medicine, United States, [4]Hospital for Special Surgery, United States, [4]Hospital for Special Surgery, , [5], United States, [6]Hospital for Special Surgery , , [7]Columbia University and Hospital for Special Surgery,

There is a need for opportunistic screening methods to improve identification of individuals poor bone quality. Our group has recently published a method for evaluation of bone quality based upon clinical MRI scans. Greater heterogeneity (irregularity) of trabecular bone texture was associated with worse bone quality-postmenopausal women with fragility fractures had greater texture heterogeneity compared to age-matched controls and individuals with greater texture heterogeneity had lower volumetric BMD and more abnormal microarchitecture by high-resolution peripheral QCT. The present study investigated relationships between MRI-based texture and biomechanical properties of bone using CT-based finite element analysis (FEA). We hypothesized that individuals with greater texture heterogeneity would have lower stiffness and compressive strength. Forty-three individuals included in this prospective study had vertebral imaging at L1-2. Trabecular bone texture was calculated from T1-weighted MRIs. A gray level co-occurrence matrix characterized the distribution and spatial organization of voxelar signal intensities to derive the following texture features: contrast (variability), entropy (disorder), angular second moment (ASM; uniformity), and inverse difference moment (IDM; local homogeneity). Texture features were calculated in five directions relative to the image plane. Analyses were performed utilizing the average of all offsets and individually in the vertical (cranio-caudal) direction to correspond with the direction of vertebral loading in FEA. Whole bone stiffness and compressive strength were calculated from phantom calibrated lumbar QCT (Abaqus and Matlab). Spearman rank correlation was used. Mean age of subjects was 61+/-10 years, 56% were female, 83% non-Hispanic White. Patients with lower whole bone stiffness had greater texture heterogeneity, specifically, higher contrast (r=-0.38, p<0.05) and entropy (r=-0.36, p<0.01) and lower IDM (r=0.39, p<0.01) and ASM (r=0.36, p<0.05, Figure). Lower compressive strength was similarly associated with greater texture heterogeneity. Relationships were comparable using the average value of texture features in all directions and the vertical direction individually. In summary, trabecular bone texture was directly related to biomechanical properties of vertebral bone. These results provide further evidence that MRI-based texture analysis may be a useful tool for identification of patients with skeletal fragility.

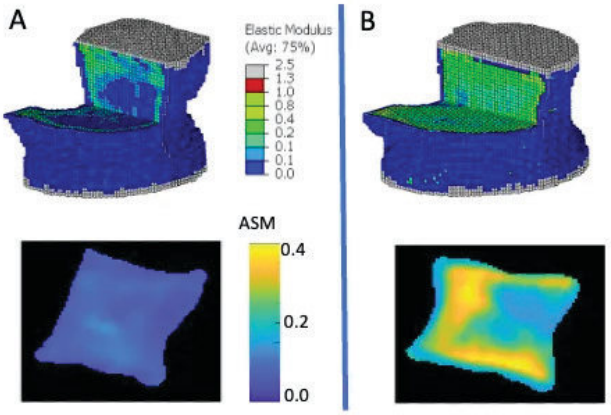

Figure: Representative vertebral images from L1 of 2 individuals using CT-based finite element analysis (FEA, above) and MRI-based texture mapping (below). Panel A is from an individual with low stiffness by FEA and low uniformity (angular second moment, ASM) by MRI. Panel B is from an individual with high stiffness by FEA and high ASM.

Factors involved in the development of cortical porosity: a cross-sectional study in healthy subjects using HR-pQCT *Jin Ikenaga[1], Ko Chiba[1], Narihiro Okazaki[2], Kazuteru Shiraishi[3], Makoto Osaki[3]. [1]Nagasaki University Graduate School of Biomedical Sciences, Japan, [2]Nagasaki University Hospital, Japan, [3]Nagasaki University, Japan

Purpose: The purpose of this study is to investigate factors involved in the development of cortical porosity using data from a cohort study assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT).Methods: The subjects were 520 healthy individuals (260 men, 260 women, 20-97 years old, all Japanese) of the cohort study (J-CaraT study: Japanese study of bone microarchitecture and mineral density in a normative cohort measured by HR-pQCT).Background information (age, height, weight, etc.), areal bone mineral density (BMD) of the lumbar spine and proximal femur by dual-energy x-ray absorptiometry (DXA), calcaneus speed of sound (SOS) by quantitative ultrasound (QUS), blood tests (WBC, RBC, Hb, Plt, Ca, P, ALP, TP, Alb, BUN, Cre, eGFR, Na, K, Cl, AST, ALT, GTP, UA, CRP, TC, TG, HbA1c, intact PTH, TRACP-5b, total P1NP, Pentosidine, 25-OH Vitamin D) was assessed.HR-pQCT imaging of the distal radius and tibia was performed (XtremeCT II, SCANCO Medical AG, Brüttisellen, Switzerland) and volumetric BMD (total BMD, cortical BMD, trabecular BMD), cortical bone microarchitecture (cortical porosity: Ct.Po, cortical thickness, etc.), and trabecular bone microarchitecture (BV/TV, trabecular thickness, trabecular number, trabecular separation, etc.) were measured. Correlations between Ct.Po and other parameters were analyzed using Pearson's correlation coefficients and partial correlation coefficients corrected for age, height and weight.Results: Ct.Po was positively correlated with age in both men and women (men: radius r=0.58, tibia r=0.41, women : radius r=0.55, tibia r=0.64, p<0.01). Ct.Po did not correlate with any measurements of DXA or blood tests. Ct.Po was negatively correlated with Ct.BMD (men: radius r=-0.45, tibia r=-0.79, women : tibia r=-0.54, p<0.01). Ct.Po was positively correlated with Tb.BMD (men: radius r=0.29, tibia r=0.35, women: radius r=0.29, tibia r=0.38, p<0.01). Ct.Po was positively correlated with Tb.Meta.BMD (men: radius r=0.37, tibia r=0.38, women: radius r=0.35, tibia r=0.42, p<0.01).Conclusion: Cortical porosity increased with age, especially after age 50 in women. None of the parameters in DXA and blood tests could be predictive markers of cortical porosity.Trabecular BMD was positively correlated with cortical porosity, and higher trabecular BMD was associated with higher cortical porosity. Its pathogenesis is unknown and further investigation is required.

LB SUN-584

Mitochondria dysfunction in osteoblast lineage cells does not impact the bone adaptive response to mechanical loading *Ana Resende-Coelho[1], Mohsin Ali[2], Aaron Warren[1], Stuart Berryhill[3], Jeff Thostenson[4], Jinhu Xiong[5], Maria Almeida[1]. [1]Division of Endocrinology and Metabolism, University of Arkansas for Medical Sciences, Little Rock, USA, United States. [2]University of Arkansas for Medical Sciences , United States. [3]Bone Biomechanics, Histology and Imaging Core (BHIC), University of Arkansas for Medical Sciences, Little Rock, AR, USA, United States. [4]Department of Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, USA, United States. [5]Department of Orthopedic Surgery, University of Arkansas for Medical Sciences, Little Rock, USA, United States

Mechanical loading, such as induced by exercise, is efficient in increasing bone formation and bone mass. The bone response to mechanical loads is less effective with aging, but the mechanisms responsible remains unknown. The number of osteoblasts and bone mass decreases in old mice due to several mechanisms of aging that are common to many organs, including mitochondria dysfunction and the production of reactive oxygen species (ROS). Superoxide anions produced during oxidative phosphorylation are promptly converted into hydrogen peroxide by superoxide dismutase 2 (SOD2) within the mitochondria. Mice with deletion of SOD2 in osteoblast lineage cells (SOD2?Osx1) have decreased bone mass. Here, we tested whether an increase in ROS and mitochondrial dysfunction in osteoblast lineage cells contribute to the decreased bone adaptive response to mechanical loading. To this end, we performed axial tibial loading in SOD2?Osx1 mice and Osx1-cre littermates controls. A reduction in SOD2 mRNA and an increase in mitoROS in bone marrow-derived osteoblastic cells from SOD2?Osx1 mice were confirmed by qPCR and MitoSOX Red staining, respectively. An 8.5N axial load was applied to the left tibia of 10-month-old female SOD2?Osx1 (n=8) and control mice (n=8) to achieve +1200 μ? peak strain at the tibial midshaft, for five consecutive days per week for 2 weeks. The load was applied in 1200 cycles with 4 Hz triangle waveform and 0.1 s rest time between each cycle. The right leg served as a non-loaded control. After sacrifice, cortical thickness was assessed by μCT at tibial midshaft and at 5 mm proximal from the tibiofibular junction. Model-estimated pairwise analysis revealed that the main effect of loading was significant (Midshaft: p=0.003, Proximal: p=0.0004). The Tukey-adjusted p-values of the 4 pairwise differences of genotype/loading combinations revealed significant differences in Osx1-cre unloaded vs. loaded for Midshaft (p=0.045) and Proximal (p=0.016) and SOD2?Osx1 unloaded vs. loaded only for Proximal (p=0.036). The interaction contrast comparing the loading differences between the genotypes revealed that the response to loading was not affected by genotype. Our results indicate that impaired mitochondrial function in osteoblast lineage cells has no major impact on the response to mechanical loading in bone, suggesting that an increase in ROS does not interfere with the response to loading with aging.

Bioprinting of a 3D Heterocellular Human Organoid for Reproducing Physiological Bone Remodeling *Chris Steffi[1], Anke de Leeuw[1], Gian Nutal Schädli[1], Xiao-Hua Qin[1], Matthias Rüger[1], Ralph Mueller[2]. [1]ETH Zürich, Switzerland. [2]ETH Zurich, Switzerland

Bone remodeling, orchestrated by osteoclasts and osteoblasts, plays a pivotal role in maintaining skeletal integrity. However, current 3D bioprinting approaches often overlook key cell types involved in bone remodeling, such as monocytes, macrophages, and osteoclasts. To address this research gap, we aimed to develop an advanced bone remodeling model by incorporating these crucial cell types and exploring their interactions in an in vitro setting.In our study, bone organoids were 3D bioprinted using alginate, gelatin, graphene oxide bioinks. By encapsulating human mesenchymal stem cells (hMSCs) or primary osteoblasts within the bioink, we mimicked the initial steps of bone development. Furthermore, to induce maturation of the hMSCs into osteoblasts, we subjected the organoids to cyclic mechanical compression, effectively stimulating cell-matrix production. Over a 4-week culture period, the hMSCs or osteoblasts successfully differentiated and mineralized the extracellular matrix. Building upon this foundation published previously, we then reseeded monocytes, osteoblasts or both into the mineralized organoids using a fibrin-based bioink. The fibrin-based bioink not only facilitated the adhesion of cells to the mineral surface but also supported their subsequent differentiation.To assess the functionality of our organoid, we cultivated it with receptor activator of nuclear factor kappa-? ligand and macrophage colony-stimulating factor, pivotal factors known to drive osteoclast differentiation and activation. The non-destructive evaluation of mineral maturation was achieved through time-lapsed micro-CT scans, which provided valuable insights into the dynamic changes occurring within the organoid. Our findings revealed a significant reduction in tissue mineral density and bone volume upon the inclusion of osteoclast precursors. These results underscored the active participation of osteoclasts in the bone remodeling process. Histology analysis confirmed the presence of multinuclear tartrate-resistant acid phosphatase-positive osteoclasts, responsible for bone resorption, as well as alkaline phosphatase-positive osteoblasts, actively engaged in mineral deposition. Multinucleated cells are shown in Fig 1. By incorporating multiple cell types and studying their interactions non -invasively, our 3D bone organoid provides a novel and sophisticated platform for investigating the intricate mechanisms underlying bone remodeling.

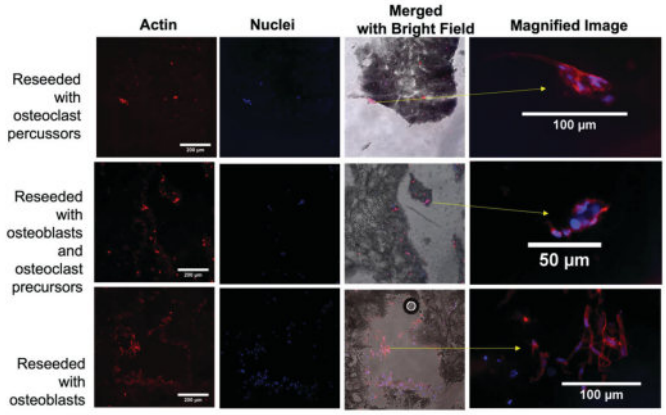

Figure 1: Confocal microscopy images of cryosections of the organoids. The actin was stained with phalloidin, and nuclei were stained with NucBlue Fixed Cell Reagent (DAPI). Osteoblast-encapsulated organoids were cultured for four weeks and were subdivided into three experimental groups. Group 1 was reseeded with osteoclast precursors, group 2 was reseeded with osteoblasts and osteoclast precursors, and Group 3 was reseeded with osteoblasts (n=3).

Effects of In Utero and Lactational Exposure to Dolutegravir-Based cART In Sprague Dawley Rats *Abhayavarshini Sridhar[1], Ryan Ross[2], Jean Harry[3], Helen Cunny[3]. [1]Rush University, United States. [2]Rush University Medical Center, United States. [3]NIH/NIEHS, United States

Introduction: Combination antiretroviral therapy (cART) has dramatically reduced the risk of Mother-to-Child HIV Transmission during pregnancy and breastfeeding. Despite its positive effects, cART increases the risk for osteoporosis in adults and may inhibit bone development in children, which increases the risk of late-life osteoporosis. Recently, the World Health Organization (WHO) has recommended dolutegravir (DTG) as the preferred treatment for pregnant women. However, the effects of early exposure to maternal DTG-based cART on bone are unclear. In the current study, we evaluated the effects of perinatal exposure to DTG/ABC (Abacavir)/3TC (lamivudine) in uninfected Sprague Dawley (SD) rats to understand its effects on bone independent of HIV.Methods: Female SD rats were bred between 10-13 weeks of age. Pregnant rats were treated with DTG/ABC/3TC or vehicle via oral gavage starting at gestational day 6. Maternal treatment continued throughout gestation and lactation. Upon weaning, the offspring received a cART-free rodent diet. On postnatal day 573 (~18 months), offspring were sacrificed. Femoral length was measured using digital hand-held calipers. Micro-computed tomography was used to evaluate trabecular bone architecture in the distal femoral metaphysis. Results were evaluated using a two-way ANOVA. To date, 10 cART and 15 vehicle treated samples have been evaluated.Results: Trabecular bone volume fraction (BV/TV) was significantly affected by treatment, with a significant 29% and non-significant 27% reduction in BV/TV of cART treated female and male rats compared to vehicle treated controls, respectively (Fig 1). cART treatment also affected trabecular number and spacing, with an overall decrease in trabecular number and increase in trabecular spacing. Femoral length was also affected by cART, with a significant increase in length in cART treated males, but not in females.Conclusion: Our prelim-

inary data suggests that exposure to DTG-based cART during early skeletal development has long-lasting negative effects on trabecular bone mass and potentially influences bone growth. Importantly, impaired bone mass accrual can increase the risk for osteoporosis later in life, and therefore children born to HIV infected mothers may be at an increased risk for osteoporosis even if uninfected themselves. Future work is aimed at assessing bone strength, matrix composition, and cellular dynamics.

Prediction of curve progression and progression to surgical threshold in adolescent idiopathic scoliosis with bone microarchitecture phenotyping by an unsupervised machine learning protocol - a 6-year longitudinal study till skeletal maturity and beyond *Guangpu Yang[3], Adam Yiu Chung Lau[2], Alec Lik Hang Hung[2], Tsz Ping Lam[3], Jack Chun Yiu Cheng[3], Wayne Lee[3], Anubrat Kumar[2], Raymond Chung Wai Wan[2]. [3]The Chinese University of Hong Kong, China. [2]Prince of Wales Hospital, China. [3]The Chinese University of Hong Kong, Hong Kong

IntroductionAdolescent Idiopathic Scoliosis (AIS) is a 3D spine deformity that may cause serious health problems. Early prediction of curve progression in AIS is essential in guiding timely interventions, and bone qualities have been shown to be an important prognostic factor in AIS. High resolution peripheral quantitative computed tomography (HRpQCT) provides low-radiation and 3D evaluation of bone microarchitecture but generates a long list of quantitative parameters hindering easy interpretation.ObjectiveOur study aims to (a) utilize unsupervised machine learning to identify hidden bone microarchitecture phenotype clusters amongst HRpQCT parameters in AIS, (b) investigate the clusters' association with risk of progression to surgical threshold in AIS, and (c) validate their association to curve progression in a separate cohort of AIS patients.MethodsA total of 207 AIS girls were staged for skeletal maturity using the validated Thumb Ossification Composite Index (TOCI) and they were all at peripubertal peak height velocity. Patients were followed up longitudinally for 6 years in the primary cohort (N=101) and for 3 years in the validation cohort (N=106). Bone qualities were evaluated by HRpQCT and three bone microarchitecture phenotype clusters were identified by Fuzzy C-Means.ResultsIn the primary cohort, patients with Phenotype-1 had normal bone characteristics. Phenotype-2 was characterized by significantly lower periosteal perimeter and trabecular area, while Phenotype-3 had significantly lower cortical density and thickness and compromised trabecular microarchitecture (Fig 1A-1C). Upon the 6-year follow-up, these bone characteristics were persistent till skeletal maturity (Fig 1D-1F), and Phenotype-3 was associated with curve progression to surgical threshold (OR=4.88, P=0.029). In the validation cohort, Phenotype-2 (adjusted OR=5.02, P=0.027) and Phenotype-3 (adjusted OR=4.22, P=0.039) were associated with curve progression >= 6°during the 3-year follow-up.ConclusionThis 6-year longitudinal study revealed that bone microarchitecture phenotype clustered by unsupervised machine learning was persistent throughout the rapid peripubertal growth period till skeletal maturity with validated success in the prediction of curve progression and progression to surgical threshold in early presenting AIS girls. With further expanded trials, these findings have important implications in guiding the clinical management of early AIS.

TATR: Modeling a Target And Timed Release strategy for TrkB agonist drug delivery to cochlear bone *Oskar Sundberg[1], Judith Kempfle[2], Boris Kashemirov[1], David Jung[3], Charles McKenna[1]. [1]University of Southern California, United States. [2]Department of Otolaryngology, Eaton-Peabody Laboratory, Massachusetts Eye and Ear Infirmary; Department of Otolaryngology, UMass Memorial Medical Center, UMass Chan Medical School, United States. [3]Department of Otolaryngology, Massachusetts Eye and Ear Infirmary, Harvard Medical School, United States

Sensorineural hearing loss (SNHL) related to aging is associated with loss of inner ear sensory hair cells (HCs), cochlear spiral ganglion neurons (SGNs), and ribbon synapses between HCs and SGNs, stimulating intense interest in therapies to restore synaptic function. Selective and potent agonists of tropomyosin receptor kinase B (TrkB) are known that can promote regeneration of SGN neurites, however local delivery of drugs to the inner ear remains a challenge due to several factors, including clearance by inner ear fluid.Bisphosphonates strongly complex calcium ions in hydroxyapatite matrices, enabling them to tightly bind to bone. This property offers the potential for bone-specific drug delivery, which has been demonstrated to provide more effective concentrations of antibiotics to infected bone tissue by attachment of the drug cargo to a bisphosphonate via a pH-sensitive linker that cleaves in situ ('target and release', TAR). Bisphosphonate-conjugated fluorescent imaging probes triggered by cathepsin K secretion at bone resorption sites have also been recently implemented.Cochlear bone is an intriguing depot target for bisphosphonates but an instigating drug release mechanism other than bone resorption is indicated to access SGNs, e.g. by adjusting the rate of drug release at physiological pH inherently, via synthetically accessible structural changes in the linker moiety ('target and timed release', TATR) (Fig. 1A). To this end, we have synthesized a small library of bisphosphonate-equipped TATR model conjugates incorporating tunable self-immolating linkers pioneered by Santi et al. and incorporating a quinine-standardized chromophore (7-AMC) as the drug cargo to facilitate determination of release kinetics. The conjugates were designed to exhibit half-lives ranging from 36 h to 450 h, with the drug release timing dependent on synthetic adjustment of the cleavable linker structure. Release kinetics were determined experimentally at pH 7.4 and the time-dependent concentrations for single compartment cochlear dilution were simulated using FluidSIM4 for bolus drug, the parent conjugate and released drug (61 uM at t = 0). As shown in Fig. 1B, under the selected conditions, the TATR-generated free drug concentration could be maintained within an arbitrary therapeutic dose range of 5 - 0.5 uM well over tenfold longer than the bolus drug concentration, demonstrating the potential of this new approach to drug delivery in the cochlea.

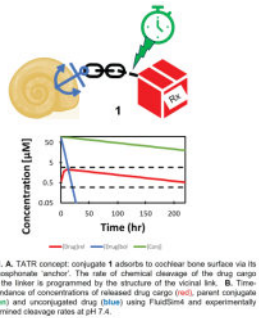

Fig 1. A. TATR concept: conjugate **1** adsorbs to cochlear bone surface via its bisphosphonate 'anchor'. The rate of chemical cleavage of the drug cargo from the linker is programmed by the structure of the vicinal link. **B.** Time-dependance of concentrations of released drug cargo (red), parent conjugate (green) and unconjugated drug (blue) using FluidSim4 and experimentally determined cleavage rates at pH 7.4.

Undercarboxylated Osteocalcin Predicts Fat Accumulation in cART Initiating People Living with HIV *Niyati Patel[1], Bryan Dulion[1], Itzel Lazcano[1], Ryan Ross[1]. [1]Rush University Medical Center, United States

The initiation of antiretrovirals (ARVs) is associated with rapid changes in bone and fat mass, which may be related phenomenon. We've reported that bone-derived undercarboxylated osteocalcin (ucOCN) is associated with fat accumulation in women living with HIV and in a mixed gender cohort of people initiating ARVs. The extent of bone and fat change and the amount of ucOCN released with ARV initiation is dependent on ART regimen. We leveraged data and serum from the AIDs clinical trial group (ACTG) to determine whether the association between ucOCN and body fat change is ARV-specific.Data and samples were obtained from a randomized clinical trial of treatment-naïve HIV-infected patients assigned to either - raltegravir (RAL), atazanavir/ritonavir (ATV/r), or darunavir/ritonavir (DRV/r), each in combination with TDF/FTC. Serum was collected at baseline (pretreatment) and 48 weeks post ARV initiation. Circulating ucOCN was measured using ELISA (Biolegend). Total body and trunk fat was assessed using dual energy x-ray absorptiometry (DXA) at baseline and 96-weeks post initiation. The change in ucOCN and fat parameters were evaluated according to treatment using a repeated measures two-way ANOVA. The association between the 48-week change in ucOCN and the 96-week change in fat parameters was evaluated using linear regression after adjusting for the baseline fat parameter. Regression analyses were run with the entire cohort and then separately by treatment.ucOCN, total body fat, and trunk fat increased over time, but there were no treatment effects. In the total cohort, change in unOCN was positively associated with total fat gain (?=0.15, p =0.046). The association between ucOCN and trunk fat was similar, but not significant (?=0.08, p =0.061). When run separately, there were no associations between ucOCN and fat in the RAL or ATV/r groups. There were, however, significant associations between the change in ucOCN and total body (?=0.35, p=0.014) and trunk fat gain (?=0.20, p=0.017) in the DRV/r group.These findings provide further confirmation of a bone-fat hormonal connection in people living with HIV and for the first time, suggest that the relationship between these two organ systems may be ARV specific. Ultimately, identifying the mechanisms associated with ARV associated complications can help to improve the quality of life of HIV infected patients.

Bidirectional Regulation of PTH and Bone Mass by Subfornical Organ *Lu Zhang[1], Nian Liu[1], Jie Shao[1], Dashuang Gao[1], Yunhui Liu[1], Yingzi Zhao[1], Chuanliang Han[1], Di Chen[1], Liping Wang[1], William Weijia Lu[1], Fan Yang[1]. [1]Shenzhen Institute of Advanced Technology Chinese Academy of Sciences, China

The central nervous system modulates the body homeostasis including bone metabolism and hormone secretion. Our recent studies found that the central nervous system modulates bone metabolism through parathyroid hormone (PTH). In mammals, PTH is secreted through the parathyroid glands and modulates bone turnover and calcium homeostasis, however mechanism underlying central neural regulation of PTH in mammals remains unknown. In our study, we identified the subfornical organ (SFO) and the paraventricular nucleus (PVN) as two important brain nuclei that responded to serum PTH and calcium changes. Using chemogenetics, we found that serum PTH was suppressed by stimulation of GABAergic neurons in SFO followed by a decrease in trabecular bone mass. Conversely, stimulation of glutamatergic neurons in SFO promoted serum PTH and bone mass. The paraventricular nucleus (PVN) is downstream of the SFO, and chemogenetic activation of glutamatergic neurons in PVN induced an increase in serum PTH and bone mass. In summary, our study demonstrates for the first time that distinct neuronal subtypes in the SFO are responsible for bidirectional regulation of serum PTH and bone metabolism, which is mediated through the PVN and the peripheral nervous system. These findings reveal important central neural nodes and will advance our understanding of the central neural regulation of PTH at the molecular, cellular and circuit level.

Hearing Loss and Risk of Osteoporotic Fracture: Population-Based Cohort Study from the United Kingdom *Yana Vinogradova[1], Nadeem Qureshi[1], Seyed Alireza Hashmeinsab[2], Daniel Prieto Alhambra[2], Laura Canals Ruiz[5], Michaela Ratzinger[5], Adrian Salas[5], Sara Khalid[2]. [1]Faculty of Medicine & Health Sciences, University of Nottingham , United Kingdom. [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford University, United Kingdom. [5]Amgen, . [5]Amgen, Austria. [5]Amgen, Argentina

BACKGROUND: Hearing loss and osteoporosis (OP) incidence both increase with age. While data suggest increased risk of hearing loss with low bone mineral density (BMD), the association between hearing loss and OP fracture is not well understood.AIMS: We assessed the association between hearing loss and major OP fracture (MOP; clinical spine, wrist/forearm, shoulder/proximal humerus and hip).METHODS: Using READ and ICD-10 diagnosis codes, we identified individuals aged >=60 years in the UK Clinical Practice Research Datalink (CPRD) GOLD database, diagnosed with hearing loss (HL; index event) from 1January2001 to 16December2021, in CPRD for >= 1 year before index event, with no history of secondary OP causes. Individuals were followed from index date to 1) MOP, or 2) death, migration/transfer out, practice last collection date, end of study or follow-up (1 year) and matched with up to 5 individuals without HL by birth and index year, sex, general practice. Incidence rates and Cox proportional Hazard Ratios (HL vs no HL; stratified by low/high fracture risk [prior fracture, OP diagnosis and/or treatment]; adjusted for ethnicity and other confounders) were calculated for MOP and hip fracture outcome. Multivariate logistic regression was used to assess risk factors for MOP and hip fracture in the HL cohort.RESULTS: 237,297 and 829,431 individuals with and without HL were included, respectively; median [IQR] age, 74 [67-81] and 72 [66-79] years, respectively; men, 52% and 53%; women, 48% and 47%. The HL cohort had longer follow-up and greater frailty (severe electronic frailty index, 5.9% vs 2.7%). After adjustment, the HL loss cohort had increased 1-year risk of MOP and hip fracture (Table). Significant risk factors for 1-year MOP and hip fracture (both) included older age, fracture history, falls, OP diagnosis, chronic obstructive pulmonary disorder, cardiovascular disease and comorbidities; additional risk factors for 1-year MOP included severe frailty and heavy alcohol use; additional risk factors for 1-year hip fracture included moderate smoking and rheumatoid arthritis.CONCLUSION: We observed a 10% higher risk of MOP and an 8% higher risk of hip fracture in individuals with hearing loss versus those without hearing loss and identified several risk factors. Our data suggest individuals with hearing loss should be considered for BMD or fracture risk assessment. Our data require external validation.

Table. Fracture incidence in individuals with and without HL – data from UK CPRD GOLD

Fracture risk	Hearing loss (N=237,297)			No Hearing loss (N=829,431)		
	Low	High	Overall	Low	High	Overall
Follow-up, median (IQR), years	4.4(2.1,7.7)	3.4(1.5,6.4)	4.2 (1.9, 7.4)	3.6(1.6,6.6)	2.8(1.2,5.5)	3.4 (1.4, 6.4)
Major Osteoporotic Fracture (MOP)						
Incidence rate (95% CI) per 1,000 person-years	16.08 (15.83, 16.34)	36.66 (35.90, 37.44)	20.11 (19.86, 20.36)	13.17 (13.04, 13.30)	32.92 (32.47, 33.37)	16.58 (16.44, 16.7)
Adjusted HR (95% CI)	1.10 (1.08, 1.12)					
Hip fracture						
Incidence (95% CI) per 1,000 person-years	4.36(4.23, 4.49)	9.28(8.9, 9.68)	5.32 (5.19, 5.45)	3.68(3.61, 3.75)	8.69(8.46,8.96)	4.54 (4.47, 4.61)
Adjusted HR (95% CI)	1.08 (1.05, 1.11)

[7]Amolyt, Canada

Introduction: the CNHR registry was established in 2014 with the objectives of identifying the etiology, presentation, natural history and current treatment of hypoPT(1)Methods: 105 patients with hypoPT were included in this prospective study. Patients completed baseline assessments including 3 site bone mineral density (BMD), trabecular bone score (TBS), fracture risk assessments, and bone biomarkers. Baseline data is presented.Results:A total of 105 participants were enrolled, mean age was 51.9 years(Y) (SD=16.4), mean age of disease onset was 39.7 Y (SD=17.3), mean duration of disease 11.3 Y (SD=8.6), mean BMI kg/m2 was 28.9(SD=7.8), 17% (n=18) were male,(M) 83% (n=87) were female(F) of whom 54% (n=47/87) were premenopausal and 46% (40/87) were postmenopausal females (PMF). 71% (75/105) had postsurgical hypoPT. 29% (n=30/105) had non-surgical hypoPT. The mean total Hip BMD gm/cm2 (n=88) was 1.04(SD=0.20), L1-L4 BMD gm/cm2 (n=86) was 1.20(SD=0.22), FN BMD gm/cm2 was 0.98(SD=0.19), 1/3 radius BMD gm/cm2 (n=81) was 0.83 (SD=0.13), TBS score (n=69) 1.33(SD=0.14). 11% (12/105) had an osteoporotic T-score (T score<=-2.5) at any site, 25% (10/40) of the PMF had an osteoporotic T score at any site and 5% (2/47) of pre-menopausal F had an osteoporotic T score at any site. 14%

(12/87) of F had an osteoporotic T score at any site and 0% of M had an osteoporotic T score at any site. A total of 14% (15/105) had a prior fragility fracture, 30% (12/40) of PMF had a fragility fracture and 2% (1/47) of premenopausal F had a fragility fracture. 15% (13/87) of F had a fragility fracture and 11% (2/18) of M had a fragility fracture. 16% (17/105) of the total sample had an osteoporotic T-score at any site OR a prior fragility fracture, 35% (14/40) of PMF, 2% (1/47) of premenopausal F, 17% (n=15/87) of F and 11% of M(1/18) had an osteoporotic T-score at any site OR fragility fracture. 11% (2/18) M had osteopenia and 57% (23/40) PMF had osteopenia. The mean age at first fragility fracture was 63.1 years (SD=12.4). 23% (3/13) had a hip fracture, 23% (3/13) had a spine fracture, 8% (1/13) had a wrist fracture, 8% (1/13) had a humerus fracture, and 15% (2/13) had a rib fracture. Conclusion:The effects of hypoPT on bone strength are not fully understood at this time. (2) We observed a significant prevalence of osteopenia (57.5%) and osteoporosis in PMF who had co-existing hypoPT in whom 35% had osteoporosis by BMD criteria or a prior fragility fracture.

Fracture risk among stroke survivors according to post-stroke disability and stroke type *Dagyeong Lee[1], Dong Wook Shin[1], In Young Cho[1]. [1]Department of Family Medicine/Supportive Care Center, Samsung Medical Center, Sungkyunkwan University School of Medicine, Republic of Korea

Background: Stroke survivors face physical and cognitive challenges, including impaired coordination and balance, which can lead to an increased dependency and a higher risk of falls. We aimed to investigate the impact of post-stroke disability status and stroke type on the risk of fracture of various site compared to the matched comparison group. Method: This retrospective cohort study used data from Korean National Health Insurance System (KNHIS) database (2010-2018) and included a total of 223,358 stroke patients and a 1:1 matched comparison group. Stroke survivors were grouped based on the severity of their post-stroke disability and stroke type (hemorrhagic vs. ischemic). The primary outcome was the incidence of newly diagnosed fracture. Cox proportional hazard regression analyses were used to calculate the hazard ratios (HR) of fractures after adjusting for potential confounders.Results: Stroke survivors had an increased risk of overall fractures compared to a matched comparison group (adjusted hazard ratio [aHR] 1.40, 95% confidence interval [CI] 1.37-1.43). This relative risk was particularly higher for hip fractures (aHR 2.42, 95% CI 2.30-2.55) compared to vertebral fractures (aHR 1.29, 95% CI 1.25-1.34) or other fractures (aHR 1.19, 95% CI 1.15-1.23). The risk of hip fractures was highest among stroke survivors with severe post-stroke disability (aHR 4.82, 95% CI 4.28-5.42), while the risk of vertebral or other fractures was highest among those with mild post-stroke disability. There was no significant difference in fracture risk between hemorrhagic and ischemic stroke survivors when stratified by disability status.Conclusion: Our findings showed an increased risk of subsequent fractures among stroke survivors, particularly those with post-stroke disability and for the hip fracture. Bone health assessment and treatment are warranted as an essential part of stroke management.

Peripheral quantitative ultrasound measured bone mineral density is associated with age and menopause in midlife women with and without HIV *Ryan Ross[1], Niyati Patel[1], Elizabeth Daubert[2], Kathleen Weber[2]. [1]Rush University Medical Center, United States. [2]Hektoen Institute of Medicine, United States

An estimated 75% of people with osteoporosis are undiagnosed. Women with HIV (WWH) and socio-demographically similar women without HIV (WWoH) have a greater osteoporosis risk than the general population due to life circumstances including poor nutrition, low physical activity, high prevalence of smoking, alcohol, and substance abuse, co-morbidities, and use of high-risk medications. Therefore, effective point-of-care osteoporosis screening is critical to identify and treat osteoporosis early and reduce the burden of osteoporotic fractures.MACS/WIHS Combined Cohort Study (MWCCS) participants from the Chicago Cook County Clinical Research Site had bone mineral density (BMDUS Index) assessed at the non-dominant distal radius using an Ultrascan650 (CyberLogic) quantitative ultrasound (QUS) instrument. Clinical, socio-demographic and lifestyle factors were collected concurrently. Menopause status was dichotomized as pre vs. postmenopausal based on participant self-report of menstrual bleeding and final menstrual period >12 months. Differences in BMD and menopausal and HIV status were compared using t-tests. Pearson correlation was used to assess the association between continuous BMD and age. Linear regression was used to test the association of BMD with menopausal status, HIV serostatus, and age. All analyses were performed using SAS software.108 (69% WWH; 31% WWoH) had a valid BMDUS Index. Mean age was 55+/-8 years, 83% were menopausal, 80% were Black, 50% were current and 31% former cigarette smokers, and 11% were former injection drug users. Mean BMD was 0.59+/-0.09 g/cm2. 32 participants (30%) were osteoporotic, 42 (39%) osteopenic, and 34 (31%) were normal. Age was negatively associated with BMD (?=-0.035, p=0.011). Postmenopausal women had significantly lower BMD (0.64 vs. 0.58, p=0.013) and there was no significant effect of HIV. In multivariate models including both age and menopause, age was the primary driver of low BMD.We investigated the feasibility of using an FDA cleared portable, rapid, QUS-based instrument in a cohort of women at high risk. Consistent with DXA, BMDUS Index was lower in postmenopausal and older women. Age was a more significant predictor of BMD than menopausal status, which could be due to the relatively small number of premenopausal women (n=18/17%). The Ultrascan650 can be an effective, rapid point-of-care screening method for identifying women at risk for low bone mass with little participant burden or cost.

Distinct defects in early innate and late adaptive immune responses typify impaired fracture healing in diet-induced obesity *Reyad Elbarbary[1], Deepak Kumar Khajuria[2], Irene Rider[3], Fadia Kamal[4], Christopher Norbury[3]. [1]The Pennsylvania State University , United States. [2]Pennsylvania State University, College of Medicine, United States. [3]Department of Microbiology and Immunology, The Pennsylvania State University College of Medicine, United States. [4]Penn State College of Medicine, United States

Most of bone fractures heal through three main phases: inflammatory, repair, and remodeling. Around 10% of fracture patients suffer from impaired healing that requires surgical intervention, a huge burden on the healthcare system. The rate of impaired healing increases with metabolic diseases such as obesity-associated hyperglycemia/type 2 diabetes (T2D), an increasing concern given the growing incidence of obesity/T2D. Immune cells play pivotal roles in fracture healing, and obesity/T2D is associated with defective immune-cell functions. However, there is a gap in knowledge regarding the stoichiometry of immune cells that populate the callus and how that population changes during different phases of healing. Here, we used flow cytometry, global RNA-seq, single-cell RNA-seq, immunofluorescence staining, and qPCR to characterize the repertoire of immune cells in the fracture callus and to identify populations specifically enriched in the fracture callus relative to the unfractured bone or bone marrow. Our analyses identified two waves of immune-cell infiltration into the callus: the first wave occurs during the early inflammatory phase, while the second takes place during the late repair/early remodeling phase. Innate immune cells were activated during the early inflammatory phase, but in later phases they returned to homeostatic numbers and activation levels. Of the innate immune cells, distinct subsets of activated dendritic cells were particularly enriched in the inflammatory healing hematoma. In contrast to innate cells, B and T cells were enriched and activated in the callus primarily during the late repair phase. The Diet-Induced Obesity (DIO) mouse, an established model of obesity-associated hyperglycemia and insulin resistance, suffers from multiple healing defects. Our data show that DIO mice exhibit dysregulated innate immune responses during the inflammatory phase, and clear defects in all lymphocyte compartments during the late repair phase, which was accompanied by substantially reduced bone formation. Further investigation of the adaptive immune cells identified specific enrichment of antigen experienced (CD44+) memory CD4+ T (TCD4+) cells in the callus of wild-type (WT) mice, which consisted primarily of effector memory (CD62L-, TEM) cells. DIO mice showed blunted TCD4+ response, and specific depletion of the TCD4+ cells in WT mice recapitulated the DIO healing phenotype and resulted in 50% reduction in bone formation. Our data characterized immune populations that are enriched/activated in the callus during two distinct phases of fracture healing. The data also identified, for the first time, defects in the healing-associated immune response in DIO mice, particularly the adaptive immune system, which will facilitate future development of immunomodulatory therapeutics for impaired fracture healing in obesity/T2D patients.

Role of Interleukin-4 in Osteogenic Differentiation of Dental Mesenchymal Cell *Hyewon Kim[1], Kyoung-Hwa Kim[2], Shin-Young Park[1]. [1]Department of Dental Science and Dental Research Institute, School of Dentistry, Seoul National University, Seoul, Korea, Republic of Korea. [2]Department of Periodontology, Dental Research Institute, School of Dentistry, Seoul National University, Seoul, Korea, Republic of Korea

Local cytokine networks, which have not yet been fully understood, control bone remodeling. Interleukin-4 (IL-4) is a pleiotropic cytokine that plays a major role in the modulation of T helper cells and mediates the regeneration of multiple tissues. This study aimed to create cells that stably express IL-4 using recombinant adeno-associated virus (AAV) and investigate its osteogenic differentiation capacity. The cDNAs of human IL-4 were cloned into AAV vectors of serotype 1, 2, 5, and 6. Rat dental pulp stem cells (rDPSCs) and human dental pulp stem cells (hDPSCs) were used. Gene transfer efficacy and the location of AAVs in cells after transduction were examined using AAV-ZsGreen1 vector. After the transduction, supernatants were collected at days 1, 3, 7, and 14. Supernatants IL-4 levels were assessed by using ELISA. Osteogenic differentiation was carried out with the IL-4 transduced cells, and their capacity was investigated by ALP staining, ARS staining, qPCR, and western blotting. AAV2-ZsGreen1 showed the highest level of gene transfer in all cell types of this study. The expression of IL-4 in rDPSC and hDPSC was high in the order of AAV2, AAV1, AAV6, and AAV5 groups. Expression of osteogenic differentiation markers, Runx2, Collagen 1, and ALP, was highest in the AAV2-IL-4 group, and ALP and ARS staining were also the darkest in the AAV2-IL-4 group. The osteogenic differentiation potential was shown to be the best in the AAV2 group. In addition, IL-4-transduced dental pulp stem cells

differentiated into osteogenic lineage via the extracellular signal-regulated kinase (ERK) signaling pathway. As a result, AAV vectors of serotype 2 showed the highest transduction efficiency in dental mesenchymal cells and the highest osteogenic differentiation potential. ERK signaling pathway play important roles in the regulation of IL-4-induced osteogenic differentiation. This study demonstrated that IL-4-transduced dental mesenchymal cells can be used in the clinical applications.

N?-(1-Carboxymethyl)-L-lysine drives cell metastasis and cancer stemness in osteosarcoma through RAGE-mediated NF-?B signaling *Ting-Yu Chang[1], Rong-Sen Yang[2], Shing-Hwa Liu[1]. [1]National Taiwan University, Taiwan, Province of China. [2]National Taiwan University Hospital, Taiwan, Province of China

N?-(1-Carboxymethyl)-L-lysine (CML), an advanced glycation end product (AGE), is believed to play a role in cancer progression. Recent studies have shown that CML promotes cancer cell growth and metastasis, however, the underlying mechanism remains unclear. Here, we found that CML and receptor of AGE (RAGE) were highly expressed in human osteosarcoma tissues with advanced stage using IHC staining (Figure 1A). The subcutaneous tumor growth and tumor weight were not affected under CML accumulation in mice induced with streptozotocin (STZ) in vivo (Figure 1B, C; n = 7/group). However, the number of nodules was significantly increased in STZ-treated mice compared to control mice in a tail-vein injection model of metastasis (Figure 1D; n = 6/group; p < 0.05). CML (25 and 50 ?M) treatment induced migration and invasion abilities (Figure 1E; n >= 3), as well as epithelial-mesenchymal transition (EMT) process in MG63 and U2OS cells. Additionally, treatment with CML in osteosarcoma cells increased the formation of tumor spheres and expression of cancer stem cell markers (Figure 1F, G; n >= 3). Pretreatment with a RAGE neutralizing antibody (5, 10 ?g/mL) blocked CML-induced cell migration/invasion, tumor sphere formation and cancer stem cell markers expression (Figure 1H-J; n >= 3). Furthermore, the activation of NF-?B was inhibited after administration of RAGE antibody (Figure 1K; n >= 3), indicating that CML promotes osteosarcoma cell migration, invasion, and stemness through the RAGE-mediated NF-?B pathway. Our study suggested that CML plays a significant role in promoting stemness and metastasis of osteosarcoma. These findings shed light on a potential link between CML/RAGE and osteosarcoma progression.

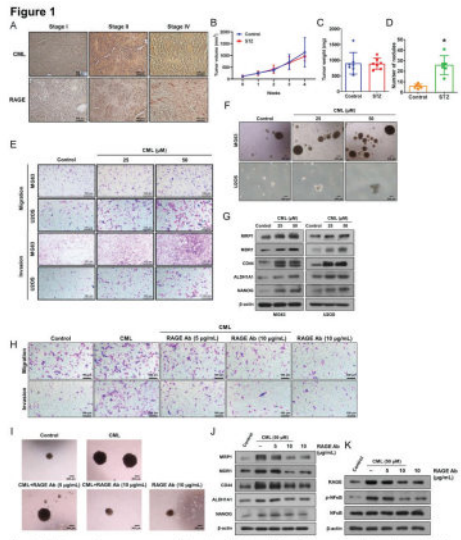

Figure 1. CML increases the cancer stemness and migration and invasion abilities of osteosarcoma cells by activating the RAGE-NF-κB signaling pathway. **(A)** CML and RAGE IHC staining in human osteosarcoma tissue microarray (n = 40) with different stages were shown. Scale bar, 100 μm. **(B, C)** MG63 cells were injected subcutaneously into the dorsal flanks of mice with or without prior treatment with STZ (n = 7 per group). The tumor growth was measured weekly, and the tumor weight was recorded after euthanizing. **(D)** MG63 cells were intravenously injected in mice with or without pretreatment with STZ. The metastatic tumor nodules in the lungs were examined and quantified. n = 6 per group. *, $P < 0.05$. **(E)** The images of migration/invasion were shown with CML (25 and 50 μM) treatment in MG63 and U2OS cells. Scale bar, 100 μm. **(F)** Self-renewal activity was determined by using the sphere formation assay in the presence or absence of CML treatment. **(G)** The protein expression of cancer stemness markers were determined in the indicated cells. **(H – J)** Blocking of RAGE using anti-RAGE antibody attenuates the CML-induced migration/invasion abilities and sphere formation. **(K)** The protein expression level of RAGE, p-NF-κB and NF-κB were examined with pretreatment with anti-RAGE antibody for 2 h in the presence or absence of CML (50 μM) treatment.

Phosphorylation of RXR ? at serine 265 is critical for the development of lung metastasis in the PYmT mouse model of breast cancer progression. *Jiarong Li[1], Richard Kremer[1]. [1]Research Institute of the McGill University Health Centre, Canada

Retinoid X receptor alpha(RXR ?) belongs to the nuclear receptor superfamily and acts as a transcription factor. RXR? forms heterodimers with other nuclear receptors, including the vitamin D receptor(VDR), the retinoic acid receptor (RAR), the PPAR gamma receptor and the thyroid hormone receptor (TR), to modulate gene transcription. Furthermore, RXR? can interact with other nuclear receptors, such as estrogen receptor (ER) and progesterone receptor (PR), to modulate the transcriptional activity of target genes involved in breast cancer progression. We previously showed that phosphorylation of serine 260 in the human RXR? leads to conformational changes and is critical for RXR? heterodimerization, translocation to the nucleus and transcriptional activity in a keratinocyte model of tumour progression(JCI1999;103(12):1729;JBC2008 ;283(8):4943JBC 2017 Jan 27;292(4):1490) .Here, we aimed to further investigate the significance of this critical amino acid phosphorylation site in vivo in a mouse model of breast tumor progression, the PYmT model. For this purpose, we used CRISPR/Cas-9 mediated genome engineering to create a FVB/Nj PYmT mouse model with serine(S)265alanine(A) point mutation in the mouse RXR? locus(the mouse amino acid equivalent of serine 260 in the human RXR ?) to prevent serine 265 phosphorylation. Cas9 mRNA and gRNA were generated by in vitro transcription and the point mutation S265A(TCA>GCA) donor oligo were co-injected into fertilized eggs for Knockin (KI) mouse production. At sacrifice the average tumor number/animal was 9.7 +/-0.2 (N=28) vs 9.67 +/-0.25 (N=24 P= 0.88) and and total tumour volume 6.85+/-0.33 cm3 vs 7.0 +/-0.23 cm3 (P=0.7) in control animals vs KI animals (). By Kaplan Meier analysis, average survival was 95 +/-1.2 days in control animals vs 92.6 +/-2.4 days in KI animals(P=0.3). In contrast, metastatic spread to lungs assessed by H & E staining at sacrifice showed that the number of metastatic lesions in KI animals more than doubled compared to controls(20 +/- 4.4 vs 8.6+/-2.2 ,P=0.028) .Signalling pathways linked to tumor progression and metastatic spread were then analyzed by real time PCR and immunofluorescence(IF) staining of breast tumors .A significant increase of AKT1 expression (2.78 fold change (FC), P= 0.012), estrogen receptor alpha (ER?)expression, (FC=8.6 ,P<0.001), CXCR4/SDF1 pathway expression(CXCR4 FC of 4.6 ,P<0.001 and SDF1 FC of 5.5, P<0.001), CD31(FC=3.7, P<0.001) as well as EMT markers mRNA expression(CDH1 FC=2.86, P=0.023, Vimentin FC=3.26 P<0.001, Zeb2 FC= 4.4 P<0.001 and snail FC= 4.2 P<0.001) were significantly increased in KI tumors compared to controls . IF staining confirmed these results.In summary, our results demonstrate that phosphorylation of the mouse RXR ? at serine 265 is critical for breast cancer metastatic spread independently of tumor growth. The underlying mechanism appears to involve ER expression, CXCR4/SDF1 and EMT.

[5]State University of New York at Stony Brook, United States. [6]MD Anderson Cancer Center, United States

Aromatase inhibitors are highly effective to treat post-menopausal, breast cancer patients by suppressing estrogen (E2) synthesis. However, many adverse effects, such as bone loss, musculoskeletal pain and increased fat deposition, limit compliance. Mechanical stimuli, like those produced from exercise and physical activity, have known benefit for bone and muscle anabolism; yet practical considerations can limit patients' ability to perform the high energy loading exerted on weak skeletal tissue. This can result in fat accumulation and weakness. Low intensity vibration (LIV), a physiologically low-magnitude mechanical signal, has preserved bone in cancer models and suppressed adiposity in ovariectomized mice and diet-induced obesity. We hypothesized that LIV would deter excess fat while suppressing the production of harmful fatty-acid byproducts and improve musculoskeletal endpoints in E2-deprived mice. C57Bl/6 female mice (n=10/group) ovariectomized at 8w of age and given daily aromatase inhibitor letrozole were treated with LIV or mock-LIV (CTL) for 4w prior to and 24w post-surgery 1x/d, 5d/w for 24w. Body composition derived from DXA scans quantified lean and fat tissue indicating a 41% (p<0.001) slowing of fat gain with LIV treatment. In addition, LIV significantly increased lean mass (p<0.02) over the 28w-treatment period. Free-fatty acids were analyzed in serum using serum metabolomics analysis. Short-chain acylcarnitines (C2-C7), fatty acid metabolites implicated in insulin resistance and metabolic disease at abnormal concentrations, were increased after 24w of E2-deprivation compared to baseline. However, LIV-mice also had lower levels of C2-C7 compared to CTL-mice. Further, medium-chain (C8-C14) acylcarnitines increased (p<0.001) after 28w of E2-deprivation but did not lower in LIV-mice compared to CTL-mice. Marginal glucose intolerance, shown by a greater area under the curve (p=0.05), was observed in LIV-mice compared to CTLmice. In summary, acetylcarnitine (C2) and hexanoylcarnitine (C7) were identified as two novel biomarkers that, in addition to medium-chain species, increased with E2-deprivation-associated musculoskeletal defects, but which only C2 and C7 decreased with LIV. These data suggest that the impact of E2-deprivation on musculoskeletal tissue supports production of potentially harmful fatty-acids in cancer patients while also supporting the role of mechanical signals in protecting lean tissue mass while limiting the accrual of fat.

Analysis of cartilage in Sox9 SUMOylation deficient mice *Megumi Iimori[1], Shizuka Yamamiya[1], Masafumi Inui[1]. [1]Laboratory of Animal Regeneration, Department of Life Sciences, School of Agriculture, Meiji University, Japan

Sox9 is a transcription factor essential for vertebrate chondrocyte differentiation. While Sox9 is known to be negatively regulated by SUMOylation in cultured cells, its in vivo role remains unclear. To address this, we generated mutant mice with a Sox9K396R mutation, where the SUMOylation target residue (lysine 396) is mutated to arginine. In these mice, the endochondral ossification process was delayed, and Sox9 target gene were upregulated in chondrocyte, indicating that Sox9 is also negatively regulated by SUMOylation in vivo. Next, we investigated the effect of this mutation on long bone development and homeostasis. Firstly, immunofluorescence analysis of embryonic long bones showed that the Col2a1-expressing chondrocyte region and the Col10a1-expressing hypertrophic chondrocyte region were wider in Sox9K396R mice compared to wild-type mice, suggesting a delay in the chondrocyte hypertrophy process. Secondly, the growth plate thickness of adult long bones were greater in 8-week-old Sox9K396R mice than in wild-type mice. However, this difference became smaller in 12 months of age, indicating a delayed growth plate closure in Sox9K396R mice. Furthermore, we investigated whether suppression of SUMOylation affects age-related degeneration of knee articular cartilage in Sox9K396R mice. We found that articular cartilage thickness was reduced in 8-week-old, 12-month-old, and 16-month-old medial femoral condyles in Sox9K396R mice compared to wild-type mice, suggesting an influence on articular cartilage thickness. At 8 weeks old, there was no difference in Safranin O staining while some wild-type articular cartilage showed reduced staining at 12 months old, whereas no reduction was observed in Sox9K396R mice. At 16 months old, Safranin O staining was reduced in both wild-type and Sox9 mutant mice. These results suggest that age-related cartilage degeneration may be partially suppressed in Sox9K396R mice by enhanced Sox9 function. In conclusion, this study demonstrates that Sox9 SUMOylation negatively regulates Sox9 function during both development and adult stages, which in turn may affect skeletal morphogenesis and cartilage homeostasis.

Bmp7 Controls Molecular And Mechanical Properties Of Articular Cartilage *Haiming Lin[1], Daniel Young[2], Lindsey Westover[3], Adetola Adesida[4], Antoine Dufour[2], Daniel Graf[1]. [1]School of Dentistry, University of Alberta, Canada. [2]University of Calgary, Canada. [3]Faculty of Engineering, University of Alberta, Canada. [4]Department of Surgery, University of Alberta, Canada

Introduction: Osteoarthritis (OA), the most common form of arthritis, is associated with cartilage degeneration. Bone morphogenetic protein 7 (Bmp7) levels are reduced in end stage human OA cartilage. Its deletion in mouse limbs leads to synovium inflammation and articular cartilage changes by 8 weeks, however, the joint appears histologically normal at 4 weeks. We recently discovered that loss of BMP7 in the nasal septum changes molecular properties of chondrocytes, predisposing to subsequent septum deviation and expression of molecular markers associated with OA. Here we tested if deletion of Bmp7 in limbs similarly leads to changes in chondrocyte properties that might be associated with subsequent cartilage degradation.Methods: To delete Bmp7 in the limbs, we created BMP7fl/fl:Prrx-Cre (mutant) mice. Knee cartilage from 4-/8-week-old mutant and control mice were collected and sent for quantitative shotgun proteomics. 8-week-old femur condyles were tested by a mechanical tester to measure stiffness. 8-week-old mice were run on a treadmill for 6 weeks. Knee joints were collected, processed histology and immunofluorescence.Results: Quantitative shotgun proteomics on control and mutant knee epiphyses followed pathway identification by using STRING shows that both femur and tibia cartilage showed significant molecular differences at 4 weeks. Amongst them were changes to extracellular matrix, protein translation, energy metabolism, and mechanotransduction. Differential expression of Col1, Fibrillin 1, Cox5a, ATP13A1, KIAA1199, RPL38, PDLIM7 were validated by immunofluorescence at both 4 and 8 weeks. Mutant cartilage was stiffer than control. After treadmill running, joints of mutants but not controls showed scattered hypertrophic chondrocytes and increased expression of ColX and MMP13.Conclusion: Our study establishes that loss of Bmp7 is associated with early molecular changes in chondrocytes before any histological changes to cartilage appearance are apparent. While mutant cartilage showed altered stiffness, OA-like changes became only apparent following strenuous exercise. BMP7 appears to maintain hyaline cartilage properties at an early stage and shows a protective effect from developing OA.

Protein phosphatase SCP4 regulates cartilage development and endochondral osteogenesis via FoxO3a dephosphorylation *Kaiao Zou[1], Pinger Wang[2], Zhen Zou[2], Wenhua Yuan[2], Jiali Chen[2], Jianbo Xu[1], Hongfeng Ruan[1], Jianying Feng[3], Xia Lin[4], Hongting Jin[5]. [1]Institute of Orthopaedics and Traumatology, The First Affiliated Hospital of Zhejiang Chinese Medical University (Zhejiang Provincial Hospital of Chinese Medicine), Hangzhou, China. , China. [2]Institute of Orthopaedics and Traumatology, The First Affiliated Hospital of Zhejiang Chinese Medical University (Zhejiang Provincial Hospital of Chinese Medicine), Hangzhou, China., China. [3]School of Stomatology, Zhejiang Chinese Medical University, Hangzhou, China., China. [4]Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, Texas, USA., China. [5]Institute of Orthopaedics and Traumatology, The First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China., China

Background: This study investigated the function of protein phosphatase SCP4 in cartilage development and endochondral osteogenesis. Methods: SCP4 knockout mice (SCP4-/-) and chondrocyte progenitor-specific knockout mice (SCP4Col2ER) were constructed and assessed for differences in bone formation using whole skeleton staining. ABH/OG staining was used to compare chondrocyte differentiation and cartilage development. Relevant pathways were analyzed using RNA-sequence and GO enrichment, further validated by immunohistochemical staining, Co-IP, and Western Blot.Results: SCP4-/- mice have a much smaller embryonic size than their littermates, this phenotype was even more pronounced in SCP4Col2ER mice. The number of chondrocytes in the growth plate was significantly reduced, the cells were irregularly arranged, increased in size, and accompanied by an increased number of vacuolated cells when compared with littermate controls. Signaling pathways and GO terms suggested that SCP4 may have contributed to this phenotype by regulating apoptosis in chondrocytes. Tunel-positive cells were increased dramatically in the growth plates of SCP4Col2ER mice, and the key pro-apoptotic proteins Caspase3/8/9 were remarkably up-regulated. The nuclear transcription factor FoxO3a has been reported to be a substrate for SCP4 dephosphorylation as well as a regulator of apoptosis. The expression of pFoxO3a was significantly upregulated in chondrocytes of SCP4Col2ER mice growth plate. In vitro, pFoxO3a and Caspase3/8/9 expression was enhanced in primary chondrocytes knocked down for SCP4. Furthermore, Co-IP and Western Blot demonstrated the dephosphorylation of FoxO3a by SCP4 in chondrocytes. Conclusions: Our results demonstrated that SCP4 has an important protective role during chondrogenesis and endochondral ossification, mediated through FoxO3a, resulting in normal skeletal formation during the embryonic period.

A novel mutation in the cysteine rich extracellular domain of the CaSR causing Familial Hypocalciuric Hypercalcemia *Naim Maalouf[1], Sarah Haroon[2]. [1]University of Texas Southwestern Medical Center, Dallas, United States. [2]UTSW, Department of Endocrinology and Mineral Metabolism, United States

A 46 yo male of Taiwanese origin was referred for evaluation and management of hypercalcemia. Hypercalcemia was first noted at age 41 years with initial labs demonstrating serum calcium of 12.0 mg/dL and a PTH reportedly in the normal range. Prior to referral to our clinic, he underwent parathyroidectomy on 2 separate occasions. Initial pre-operative localization studies were inconclusive, and he underwent neck exploration with excision of an enlarged right superior parathyroid gland. Following his first neck surgery, his serum calcium remained elevated. He underwent selective venous sampling of neck veins and a chest CT followed by excision of thymic tissue which was thought to contain parathyroid tissue on frozen section. The permanent section, however, revealed no evidence of parathyroid tissue. Due to persistent hypercalcemia he was referred to our clinic. He denied a history of kidney stones but did endorse polyuria, polydipsia, thirst and fatigue. He had a now 2-year-old son who was noted to be hypercalcemic without a concomitant PTH level during a hospital admission for diarrhea at the age of 8 months. No other family members had known hypercalcemia. He had normal cognition and his physical exam was unremarkable. Labs demonstrated a high Ca of 10.6-11.2 mg/dL, low phosphorus of 2.2 mg/dL and PTH of 34 pg/mL. His GFR was >60 mL/min. Magnesium was 1.8 and 2.6 mEq/L on different occasions (normal range 1.4-1.8 mEq/L). 24 hour urine calcium values were 143 and 198 mg/day with a Ca/Cr clearance ratio of 0.009 and 0.012, respectively. DXA showed T scores of -1.7 at lumbar spine, -1.3 at L hip, and +0.1 at the 1/3 radius. Due to findings of hypercalcemia, non-suppressed serum PTH, and relative hypocalciuria, familial hypocalciuric hypercalcemia (FHH) was suspected. He was referred for genetic testing which revealed a heterozygous variant c.1661T>A in exon 5 of the CASR gene, resulting in amino acid change 554 from isoleucine to asparagine (p.I554N). This novel base change was felt to represent a pathologic missense mutation in the CASR even though it has not been previously described, as substitutions at the adjacent amino acids (553 and 555) have been reported in association with FHH. The mutation is located in the cysteine-rich extracellular domain of the calcium sensing receptor.

Romosozumab Therapy in Adult Monogenetic Osteoporosis *Rodrigo Montero-Lopez[1], Alexandra Blaschitz[1], Katharina Tischlinger[1], Markus Klinger[2], Daniel Cejka[3], Wolfgang Högler[1]. [1]Department of Paediatrics and Adolescent Medicine, Johannes Kepler University Linz, Linz, Austria, Austria. [2]Institute of Nuclear Medicine, Kepler University Hospital, Linz, Austria, Austria. [3]Dept. of Internal Medicine III, Nephrology, Transplantation Medicine, Rheumatology, Geriatrics, Ordensklinikum Linz-Elisabethinen, Linz, Austria., Austria

BACKGROUND: Romosozumab (ROMO) is a monoclonal antibody targeting sclerostin, an inhibitor of the Wnt/ß-catenin pathway. Clinical trials show benefits for postmenopausal women or men over 50 years with osteoporosis. However, there have been no studies assessing the effect of ROMO on monogenetic osteoporosis. Here we describe the impact of ROMO in adult patients with WNT1 and COL1A1 mutations.METHODS: We conducted an analysis of two patients with monogenetic osteoporosis treated with ROMO (210mg s.c.), along with oral colecalciferol and calcium supplementation. Densitometry (Hologic Horizon; lumbar spine, femoral neck) and HRpQCT (Scanco XtremeCT-II; tibia 22.0mm, tibia 30%) were conducted before and after 12 months of treatment. HRpQCT results were compared with those of healthy controls (unpublished data).CASE 1: A 40-year-old Caucasian man presented with a history of long-bone fractures from moderate trauma since early childhood and multiple vertebral fractures. Whole Exome Sequencing identified a novel, heterozygous variant in WNT1 (c.761C>A). DXA-measured bone mineral density (BMD) was significantly reduced (LS-BMD T-score -6.8, FN-BMD T-score -4.1). Tibial trabecular volumetric BMD was very low (Tb.vBMD Z-score -4.1) with a cortical vBMD within normal range (Ct.vBMD Z-score +1.0). After one year of ROMO, aBMD had substantially increased (LS-BMD +41%, FN-BMD +24%). Volumetric BMD increased in trabecular compartment (Tb.vBMD +7.5%, Ct.vBMD -0.2%). No fractures or cardiovascular events were reported.CASE 2: A 50-year-old Caucasian woman was diagnosed in infancy with osteogenesis imperfecta type I with multiple long-bone and vertebral fractures. NGS Panel showed a novel heterozygous variant in COL1A1 (c.2334dup). Prior to starting ROMO she had reduced BMD (LS-BMD T-score -2.2, FN-BMD T-score -2.4). Tibial Tb.vBMD was low (Z-score -4.3), Ct.vBMD was within normal range (Z-score +0.0). After 12 months of ROMO, aBMD increased by 6-9% (LS-BMD T-score -1.5, FN-BMD T-score -2.0). Tb.vBMD increased substantially (+78.7%, Z-score -3.6) and Ct.vBMD decreased slightly by -3.1% (Z-score -0.4). Two radius fractures occurred 1 and 6 months after starting ROMO and no cardiovascular events were reported.DISCUSSION: ROMO treatment for 12 months substantially improved aBMD and vBMD, most notably in trabecular bone. Larger cohorts are required to confirm if ROMO may be an effective therapeutic option for monogenetic osteoporosis caused by WNT1 and COL1A1 mutations.

Multiple Vertebral Fractures (VFs) as the presenting manifestation of Amyloidosis and response to bisphosphonate (BP) therapy with long-term follow-up *Vijayalakshmi Donthireddy[1], Abeselom Geletu[1], Sudhaker Rao[2], David Willens[1]. [1]Henry Ford Health, United States. [2]Henry Ford Hospital, United States

Spontaneous VFs are a rare clinical presentation of amyloidosis, which commonly affects kidney, heart, liver, and bone marrow. Only 16 cases have been reported. Although BPs have been used in a few patients, long-term outcome with such therapy is unknown. We present a 52y old white woman who was otherwise healthy till April 2016 spontaneously developed upper and lower back pain. Imaging studies confirmed multiple VFs T3, T7, and T12 and underwent vertebroplasty. This was soon followed by additional VFs of L1 and L2 and had vertebroplasty again. Extensive evaluation including kidney biopsy confirmed primary amyloidosis. She received stem-cell transplant in 2017 with stable course since. Spine BMD T-score prior to VFs was -2.7 and femoral neck BMD was -1.5. Serum levels of Ca (total and ionized), PTH, 25OHD and 1,25-D were all normal. Weekly alendronate was started soon after the initial VFs in early 2017 until 2021, then switched to zoledronic acid (received 2 courses in 2021 and 2022) with 40-50% decline in CTX and osteocalcin in response to BP therapy. No new VFs or other fractures occurred since 2016 except the cascading VFx related to previous vertebroplasty. Her amyloidosis is now in remission.Serial CT scans before and after sustaining VFs and the most recent are shown in Figure. L1 and L2 VFs occurred soon after vertebroplasty of T12. Also, other thoracic VFs occurred after T3 and T7 vertebroplasty a few months later, a cascading VF phenomenon well described in patients with osteoporosis. But no new VFs or other fractures since July 2021.To the best our knowledge this is the longest BP treated patient with amyloidosis and VFs with no progression of VFs or other fractures. It is unclear if VFs were due to amyloid deposits within the vertebrae compromising bone quality or due to usual OP, although multiple VFs at this young age is very unusual. Also, it is unclear if the lack of progression of VFs or other fractures an expected response to BP therapy or remission of amyloidosis with stem cell transplantation. For now, we plan to continue BP therapy with close monitoring to avoid AFF. We contemplated anabolic therapy, but reluctant to consider because of potential for malignancy. Suggestions and experiences are welcome!

LB SUN-606

Infigratinib Reduces Premature Bone Fusion at Sutures in a Mouse Model of Craniosynostosis *Greg Holmes[1], Susan M. Motch Perrine[2], Abdul Rashid Abdulai[1], Yuhan Hsi[2], Cecil S. Qiu[3], Morgan L. Paull[3], Bhavik P. Shah[3], Joan T. Richtsmeier[2], Ethylin Wang Jabs[1]. [1]Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, United States. [2]Department of Anthropology, Pennsylvania State University, United States. [3]QED Therapeutics, Inc, United States

Purpose: Fibroblast growth factor (FGF) signaling is a key regulator of skeletal development. Gain-of-function receptor mutations of FGFR1, FGFR2, and FGFR3 result in a variety of craniosynostosis (CS) syndromes, in which suture fusion prevents normal skull development and leads to increased intracranial pressure, adversely affecting neurological development. Pharmacological antagonism of the FGFR signaling pathway is an attractive avenue for ameliorating the effects of activating FGFR mutations. Infigratinib is a selective FGFR1-3 tyrosine kinase inhibitor, and therefore may be an effective therapeutic agent for the amelioration of premature suture closure and other sequelae of FGFR activation. Infigratinib treatment improves long bone growth in mouse models of achondroplasia and of hypochondroplasia, and it is being evaluated in clinical trials for children with achondroplasia. To determine the efficacy of infigratinib in reducing the severity of suture fusion we used the Crouzon syndrome mouse model (Fgfr2cC342Y/+) that has progressive postnatal coronal suture fusion. Methods: Unaffected wildtype (WT) mice were treated with vehicle and Fgfr2cC342Y/+ littermates were treated with either vehicle, 0.5 mg/kg, or 2.0 mg/kg infigratinib by daily subcutaneous injection between postnatal days (P) 2 and 15 (n=10 per treatment group). After sacrifice on P16, skulls were scanned by microcomputed tomography (microCT). Scans were acquired using the 300 kv tube of a GE v|tome|x L300 nano/microCT scanner alongside a hydroxyapatite (HA) phantom with known densities. Results: MicroCT revealed a wide array of changes in the degree of suture fusion and skull shape in this model. The degree of suture fusion in Fgfr2cC342Y/+ mice treated with 2.0 mg/kg infigratinib was equivalent to that of WT littermates for the coronal, maxillary-palatine, and lateral occipital-squamous sutures as well as the presphenoid-sphenoid synchondrosis. Morphological analysis of the cranial vault and the mandible revealed that shape was most similar between specimens treated with 2.0 mg/kg infigratinib and WT littermates. Conclusions: Treatment with 2.0 mg/kg infigratinib reduced premature bone suture fusion in a mouse model of craniosynostosis, suggesting the potential to ameliorate intramembranous bone phenotypes in conditions like craniosynostosis.

Sclerostin Antibody induces changes in Osteogenesis Imperfecta craniofacial bone *Hsiao Sung[1], Braden Terner[1], Hane Eun[1], Esmeralda Blaney Davidson[2], Kenneth Kozloff[1]. [1]University of Michigan, United States. [2]Radboud umc, Netherlands

Osteogenesis Imperfecta (OI) is characterized by low bone density and high bone fragility. Craniofacial and dentoalveolar abnormalities are present in all OI types. Currently, antiresorptive bisphosphonates are widely used to reduce bone fragility in OI. However, there are limitations to its use, such as the potential for osteonecrosis of the jaw, leading to the exploration of alternative anabolic approaches to the disease. Multiple studies have shown that the sclerostin antibody (SclAb) increases long bone mass and strength in OI models. However, little is known about its effect on craniofacial bone and teeth and whether

there is any variation in its effectiveness on endochondral and intramembranous-originated bone.3-week-old WT and Brtl/+ OI mice received subcutaneous SclAb (SclAb VI, Amgen, and UCB) treatment or vehicle injection (PBS) at 25 mg/kg, 2X/week, for five weeks. Skulls were scanned using high-resolution MicroCT (Skyscan 1176, Kontich, Belgium). Dragonfly 2.0 (ORS, Denver, USA) was used to delineate regions of interest and to perform measurements of the maxilla, mandible, temporomandibular joint (TMJ), and teeth. Statistical analysis was performed with two-way ANOVA, $p<0.05$ was considered significant. SclAb significantly increases the bone volume fraction in both WT (maxilla-79%, mandible-89.5%) and Brtl/+ (maxilla-67.8%, mandible-75.4%) (fig.1). These results are consistent with previous long bone and alveolar bone defect regeneration studies. SclAb also increases the bone thickness of TMJ articular tubercle and mandibular condyle neck in WT and Brtl/+ (0.35mm, 0.27mm versus control WT 0.34mm and control Brtl/+ 0.24mm) (fig.2). An increased TMJ thickness was previously observed in sost-/- mice. Brtl/+ mice have increased alveolar bone loss with a high presence of osteoclastic activity compared with treated Brtl/+. SclAb increases the dentin/tooth ratio (Fig.3), suggesting potential SclAb effects on odontoblasts. We did not observe any cementosis as reported in sost-/- mice. Importantly, SclAb impacts bone thickness but has minimal effects on the maxilla, mandible, and TMJ lengths, consistent with our previously reported cranial findings.In conclusion, SclAb increases craniofacial bone mass across multiple bone types in an OI mouse model, including dentin and condylar neck thickness. These SclAb-induced effects have potential clinical applications for jawbone and tooth regeneration for OI and other craniofacial bone disease patients.

Unique chemical probes to assess Ghrelin proteolysis in plasma of men and women with obesity *Daniel Castrogiovanni[1], Tyler Lalonde[2], Leonard G. Luyt[3], Jean-Alain Fehrentz[4], Maria F Andreoli[5], Mario Perello[1], Nicolas De Francesco[1]. [1]IMBICE, UNLP, CONICET, CIC-PBA, Argentina. [2]Scintica Instrumentation Inc. , Canada. [3]University of Western Ontario , Canada. [4]IBMM, France. [5]IDIP and CONICET, Argentina

Since plasma ghrelin can undergo des-acylation and proteolysis, the aim of this work was to investigate the extent to which enhancement of these reactions is associated with the decrease of ghrelin in plasma after food intake or in individuals with obesity. Unique analogs of natural ghrelin were developed to monitor changes in plasma ghrelin levels. Levels of ghrelin, desacyl-ghrelin (DAG), glucose, insulin, ghrelin des-acylation, and ghrelin proteolysis were assessed in plasma before and after a test meal in 40 people (n=21 males) with normal weight (NW, n=20) or overweight/obesity (OW/OB, n=20). Preprandial ghrelin and DAG levels were lower, whereas preprandial ghrelin proteolysis was approximately 4.6-fold higher in the plasma of males that were OW/OB. Ghrelin proteolysis in males positively correlated with glycemia. Ghrelin and DAG levels were also lower in females with NW or OW/OB. Ghrelin and DAG levels decreased postprandially in males and females, independently of BMI, and ghrelin proteolysis increased postprandially approximately 2 folds only in individuals with NW. Ghrelin des-acylation remained unaffected by BMI or feeding status in both sexes. This current study highlights that ghrelin proteolysis increases in males with obesity as well as after a meal in lean individuals. Therefore ghrelin proteolysis may be an important checkpoint and, consequently, a putative pharmacological target to control circulating ghrelin levels in humans.

Effect of vitamin D supplementation on fracture healing: a randomized controlled trial in a paediatric population with hypovitaminosis D *Michael Bullen[1], Christine Rodda[2], Peter Pivonka[3]. [1]University of Melbourne, Western Health, Australia. [2]University of Melbourne, Australia. [3]Queensland University of Technology, Australia

Objective: The primary objective of this study was to assess the effect of vitamin D supplementation on fracture healing in a vitamin D deficient paediatric population.Methods: We performed a double blind, randomized placebo-controlled trial in participants aged 8 - 18 years who had sustained an acute distal radius fracture managed with cast immobilisation. Participants with a serum vitamin D level of 12.5 - 50 ng/mL were randomly allocated to a single oral dose of 150,000 international units of cholecalciferol or placebo. Follow-up was performed at two, six and twelve weeks post-injury. The primary outcome was peripheral quantitative computed tomography (pQCT) derived measures of fracture healing at six weeks post-injury. Secondary endpoints comprised clinical and plain radiograph fracture healing assessment, changes in bone mineral density (BMD) and cross-sectional area (CSA) in the uninjured limb, and dietary calcium intake.Results: A total of 28 participants (median age 12 y; 79 % male) were randomized, with complete primary outcome data for 23 (82 %). There was no difference in fracture callus trabecular density (coefficient 13.95; 95% confidence interval [CI], -23.45 to 51.35; p=0.44), cortical density (coefficient 0.96; 95% CI, 0.83 to 1.11; p=0.55), trabecular area (coefficient -24.5; 95% CI -59.2 to 10.11; p=0.15) or cortical area (coefficient 0.88; 95% CI 0.58 to 1.33; p=0.53) between the two groups. The strength-strain index was higher in the placebo group compared to the vitamin D group (coefficient 64; 95% CI 9.05 to 118.94; p=0.025). There was no difference in clinical or plain radiograph assessments of fracture healing, nor BMD & CSA of the uninjured limb, and dietary calcium intake between the two groups.Conclusions: Vitamin D3 supplementation did not improve fracture healing in a vitamin D deficient paediatric population, as measured by pQCT.

Osteocalcin Improves Glucose Tolerance, Insulin Sensitivity and Secretion *Terry Dowd[1], Noorulain Paracha[1], Evan Kello[1], Paul Mastrokostas[1], Devorah Segall[1], Lawrence Mitelberg ?[1], Naif Hassan[1], Yosef Gedailovich[1], Alexis Rizzo[1]. [1]Brooklyn College, United States

Osteocalcin deficient mice (Ocn-/-), on a mixed 129/BL6J background, were reported to show glucose intolerance, reduced insulin sensitivity and insulin secretion at 1-6 mos of age. In contrast, two studies in Ocn-/- mice on different backgrounds (C3H/BL6 (5-6 mos.) and C57BL/6N (5 and 9 mos.)) found no effect on glucose metabolism. To determine the role of Ocn in glucose metabolism we conducted glucose tolerance tests (GTT), insulin tolerance tests (ITT) and glucose stimulated insulin secretion (GSIS) on 9.5 month-old male Ocn-/- and Ocn+/+ mice on a pure C57BL/6J background and fed a normal chow diet. Mice were fasted for 5 hours during the day with access to water for GTT and ITT. The GTT and ITT were separately conducted by an intraperitoneal injection of either glucose for GTT (2 g/kg BW) or insulin (0.5 U/kg BW) for ITT and measurement of blood glucose at 0, 15, 30, 60, 90 and 120 minutes post injection via a tail nick and glucometer. Blood glucose values vs. time were plotted as mean +/- SEM. Two-way repeated measure ANOVAs were used to assess significance for all tests. The GTT results for 20 male Ocn+/+ and Ocn-/- mice gave a significant main effect of osteocalcin ($p< 0.01$) with significantly ($p <= 0.05$) greater blood glucose for Ocn-/- at most time points. Insulin sensitivity (ITT) results for 19 Ocn+/+ and 28 Ocn-/- also showed a significant main effect of osteocalcin ($p <= 0.05$) with significantly increased blood glucose at several time points for Ocn-/- indicating insulin insensitivity. Insulin secretion (GSIS) was conducted after an overnight fast (12 hours) and an intraperitoneal injection of glucose (3 g/kg BW). Blood insulin concentrations were measured at time 0, 3, 8, 17 and 28 minutes post glucose injection using an insulin elisa assay. A significant main effect of osteocalcin ($p <= 0.05$) was shown with insulin significantly reduced in Ocn-/- at several time points. Our results confirm the role of Ocn in glucose metabolism and insulin sensitivity and demonstrate a role in insulin secretion in older male mice on a C57BL/6J background. The results may differ from previous reports due to differences in background, age, or experimental procedures which led to the discrepancies. Our data indicates a delayed onset of the effect of Ocn on glucose metabolism occurring at 9.-10 months in male C57BL/6J mice and highlights the importance of background on phenotype. These results may be relevant to the elderly since osteocalcin is reduced with age.

AAV2-FGF18 Gene Therapy Protects Cartilage and Subchondral Bone in a Mechanically Induced Model of Osteoarthritis *Alex Goraltchouk[1], Judith Hollander[2], Jingshu Liu[3], Ellyn Xu[3], Frank Luppino[2], Li Zeng[3], Alexey Seregin[1]. [1]Remedium Bio, Inc., United States. [2]Remedium Bio, Inc, United States. [3]Department of Immunology, Tufts University, United States

Osteoarthritis (OA) is a debilitating degenerative pathology of cartilagenous joints affecting over half a billion people. Prevalence rates continue to grow, driven mainly by aging global population and increasing rates of obesity. To date, only the chondroanabolic treatment regimen of a series of intra-articular injections of Fibroblast Growth Factor 18 (FGF18) has demonstrated clinically meaningful efficacy in placebo-controlled human trials. We induced OA in adult male Sprague-Dawley rats using destabilization of the medial meniscus (DMM). Treatment included rhFGF18 (positive control), PBS (negative control), and 3 dose levels of AAV2-FGF18. Durability, redosability, and biodistribution were measured by quantifying nLuc bioluminescence. Transcriptomic analysis was performed by RNA-seq on primary human chondrocytes in culture and rat knee joints. Morphological analysis was performed on whole knee joints stained with Safranin O/Fast Green and anti-PRG antibody. Dose-dependent reductions in cartilage defect width and depth were observed following AAV2-FGF18 treatment. Defect width was reduced by up to 76% and cartilage thickness in the thinnest zone was increased by up to 106% relative to control. PBS-treated joints exhibited severe cartilage erosion, bone void formation, subchondral bone remodeling, and cases of near-complete subchondral bone collapse. In contrast, AAV2-FGF18-treated joints appeared significantly more anatomically normal, with only marginal cartilage erosion and regional glycosaminoglycan loss. While effective at reducing cartilage lesions, treatment with repeated rhFGF18 injections increased joint swelling and decreased PRG4 expression. In contrast to in vitro RNA-seq analysis, which showed a high degree of concordance between rhFGF18- and AAV2-FGF18-treated chondrocytes, in vivo transcriptomic analysis revealed few gene expression changes following protein treatment, suggesting transiency of effect. Conversely, gene therapy exhibited a high degree of localization and durability (>12 months) in both healthy and OA joints, upregulating several chondroanabolic genes while downregulating OA and fibrocartilage associated transcripts.Intra-articular FGF18 gene therapy treatment for OA can provide benefits to both subchondral bone and cartilage, with a high degree of durability and localization. In contrast to rhFGF18 protein injections, the gene therapy is not limited by pharmacokinetics and possesses superior safety and efficacy.

Hierarchical surface roughness using a 3D-printed interbody implant promotes optimal bone formation and integration on Fluorescence image cytometry *Ali Kiapour[1], Xiaonan Xin[2], Elie Massaad[3], John Shin[3], David Rowe[4]. [1]Massachusetts General Hospital, Harvard Medical School, . [2]Department of Reconstructive Sciences, University of Connecticut, United States. [3]Department of Neurosurgery, Massachusetts General Hospital, Harvard Medical School, United States. [4]University of Connecticut Health Center, United States

INTRODUCTION: Novel 3D-printed titanium implantable devices with the surface roughness which is the by-product of the printing process can yield to better tissue-implant interaction and fusion as opposed to conventional PEEK or smooth titanium implants. This study aimed at comparing 3D-printed Ti (P3D) with smooth Ti (SmTi) and PEEK surfaces for their bone differentiation capability by utilizing transgenic bone marrow stem cells that fluoresce when osteogenesis is initiated. Also, gene expression was evaluated longitudinally with a comprehensive panel of bone-related genes that include a master transcriptional regulator of bone formation, and early-and late-stage markers for bone differentiation. METHODS: We evaluated mesenchymal stem cells obtained from the bone marrow of a transgenic mouse in which the expression of two genes critical for the proper mineralization of bone could be monitored fluorescently (Fig-1a). The P3D surface with hierarchical surface roughness (Fig-1b) was produced Electron-Beam Melting (EBM) 3D-Printing process. The surface characterization was done scanning electron microscopy. The SmTi and PEEK discs with matching sizes were also obtained. All samples were cleaned and sterilized before seeding.RESULTS: Significantly greater percentage of BMSC-derived progenitor cells were osteogenic on the P3D Ti surface at day 22 (Fig-1c, $p<0.05$) as compared to smooth Ti & PEEK. Approximately 86% of the stem cells were osteogenic on the P3D surface compared to less than 49% and 70% on the PEEK and SmTi surfaces, respectively. The magnitude of gene expression was substantially higher for most markers on the P3D surface (greatest at day 14) vs. PEEK or SmTi.DISCUSSION: The P3D-printed surface tested in the current study enabled a more rapid and robust bone formation. The P3D rough Ti surface enabled a significantly greater proportion of the BMSC-derived progenitor cells (vs. PEEK and SmTi) to enter the osteogenic lineage and resulted in significantly greater gene expression for a broad spectrum of bone-related molecules that includes a master regulator of bone differentiation, early bone markers and late bone markers associated with bony mineralization and osteocyte formation. Accelerated osteogenic differentiation indicative of osteocyte formation was observed at an early timepoint the P3D surface relative to the smooth surfaces as indicated by large and significant increases in the late bone markers of Blap and Phex.

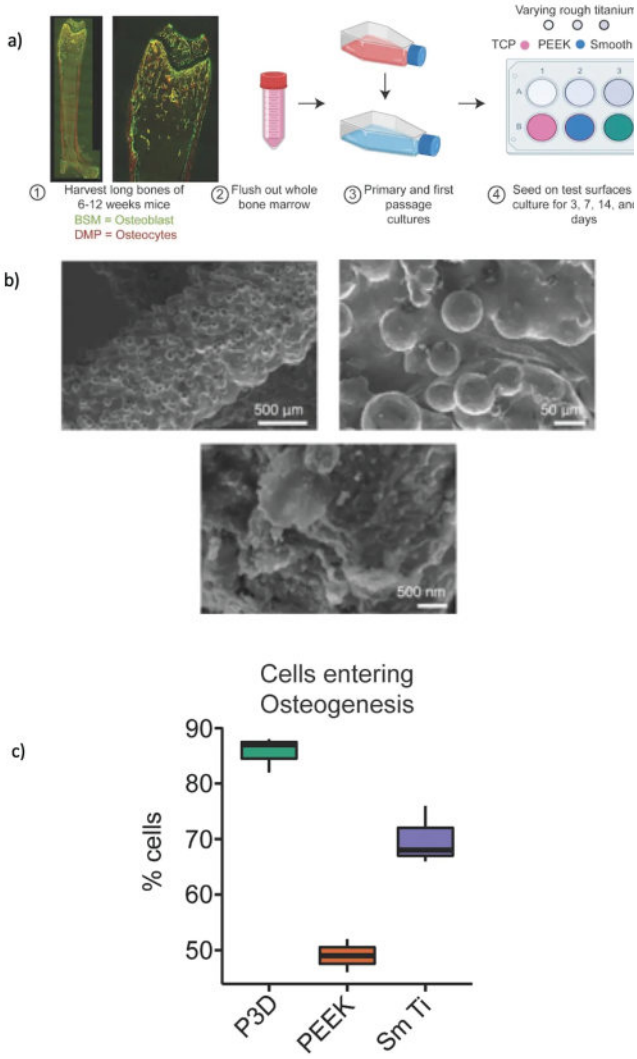

Figure 1: a) Experiment setup. b) Scanning Electron Microscopy of the P3D. c) Percentage of cells that entered osteogenesis at day 22.
surface at three different magnifications shows hierarchical surface roughness spanning from the macro to nanometer scale. A. 500 micrometer scale (macro). B. 50 micrometer scale. C 500 nanometer scale (nanometer scale).

LB SUN-613

Bibliometric analysis highlights lesser-studied pathways in bone remodeling
*Emily Davis[1], Jacob Snyder[1], Elicza Day[1], Gabriella Battiston[1], SIERRA STREET[2], Kyung Kang[1], Julia Hum[1], Jonathan Lowery[1]. [1]Marian University, United States, [2],

Osteoporosis (ie, low bone mass) is a common medical condition that places individuals at elevated risk of fracture and greater likelihood of disability, loss of independence, and death. Both anti-resorptive and anabolic medications are available and are generally successful at stabilizing and/or promoting gains in bone mass. However, each current medication has significant drawbacks which present considerable challenges for the long-term management of this chronic condition. Unfortunately, there are relatively few new candidate therapies in the drug development pipeline, which presents an urgent need to identify new treatment targets for increasing bone mass. However, a report from 2018 identified a striking lack of heterogeneity among molecular pathways studied in the bone remodeling field, with just three pathways (Wnt, Mitogen-activated protein (MAP) kinase, and the Transforming Growth Factor (TGF)-beta superfamily) accounting for more than 50% of publications and 46% of NIH-funded grants between 2008-2017. Further, adding Parathyroid Hormone (PTH), this list of four pathways accounts for nearly 55% of United States National Institutes of Health (NIH) grants funded during that period. In this study, we update the prior analysis to the time period of 2018-2022 to a) examine the heterogeneity of molecular pathways studied in the bone remodeling field in that time and b) determine if functional evidence exists for lesser-known pathways which might hold therapeutic potential. We used a combination of search terms in the PubMed and NIH RePORTER databases to detail the relative popularity of more than 144 pathways, with the RANK Ligand (RANKL) pathway having the greatest frequency of publications and grants (32.5% and 16.1%, respectively) from 2018-2022. For publications, RANKL is followed by TGF-beta superfamily (26.6%), MAP kinase (22.2%), Fos/Jun (22%), and Wnt (21.2%). Given that many of these publications overlap, we combined search terms to find that just these top five pathways account for 75.3% of publications in the bone remodeling field from 2018-2022. The popularity of just these top five pathways (by publication) in NIH-funded grants exceeds 48% of all grants awarded in the bone remodeling field from 2018-2022. Adding PTH to this list accounts for greater than 52% of NIH-funded bone remodeling grants in 2018-2022. This current lack of diversity in research may restrict discovery of novel therapeutic approaches. Our study highlights several pathways for which functional evidence supports a role in the regulation of osteoblasts and/or osteoclasts in vivo. Future work is required to determine therapeutic potential for these pathways intersect and we call for an expansion into lesser-studied pathways in order to broaden the collective focus of the field.

Synergistic effects of lysophosphatidic acid (LPA) and 1,25-dihydroxy vitamin D in osteocytes to promote the skeletal synthesis of fibroblast growth factor-23 (FGF23)
*Birol Ay[1], Sajin Marcus Cyr[2], YORIHIRO IWASAKI[3], Stefan Offermanns[4], Petra Simic[2], Murat Bastepe[5]. [1]Massachusetts General Hospital/Harvard Medical School, United States, [2]Endocrine Unit, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, United States, [3]Massachusetts General Hospital, , [4]Department of Pharmacology, Max Planck Institute for Heart and Lung Research, Germany, [5]Massachusetts General Hospital, Harvard Medical School, United States

The synthesis of the bone-derived phosphaturic hormone fibroblast growth factor 23 (FGF23) is stimulated by lysophosphatidic acid (LPA) in response to kidney injury. Previous studies suggest that skeletal FGF23 production increases upon activating the heterotrimeric G?q/11 signaling pathway. Since LPA acts via multiple G proteins, including G?q/11, we hereby investigated the role of G?q/11 signaling in LPA-induced FGF23 synthesis. We also explored the cellular pathways downstream of LPA, using mice with conditional ablation of G?q and G?11 in osteocytes (G?q/11Dmp1KO). We also used osteocyte-like OCY454 cells, in which LPA was shown to stimulate FGF23 synthesis when administered with 1,25-dihydroxy vitamin D (1,25D). Serum total and intact FGF23 levels were mildly elevated in 2-month-old G?q/11Dmp1KO mice compared to control littermates (1.3-fold and 1.2-fold, respectively) at baseline. The levels rose in both controls (1.4-fold, p=0.0004 and 1.4-fold, p=0.0004, respectively) and G?q/11Dmp1KO littermates (1.5-fold, p=0.0001 and 1.5-fold, p=0.0001, respectively) 24 hours after intraperitoneal LPA (50 mg/kg) injection. In OCY454 cells, LPA/1,25D treatment led to a significant increase (5-fold, p=0.007) in FGF23 mRNA levels at 24 hours, but G?q/11 inhibitor YM254890 could not blunt this elevation. Whole transcriptome analysis identified a greater number of differentially expressed genes (DEG) after a 2 or 8 hour-treatment with LPA and 1,25D together (1157 and 657 DEGs) than LPA (306 and 475 DEGs) or 1,25D alone (12 and 140 DEGs), suggesting synergism between LPA and 1,25D. Several DEGs were unique or dramatically more expressed in the LPA/1,25D treatment group compared to the individual treatments, including MAPK signaling targets Dusp5 and Dusp6. Several cellular pathways unique to the combined LPA/1,25D treatment were also identified, including MAPK and NF-KB signaling. Accordingly, LPA/1,25D treatment led to ERK1/2 phosphorylation in OCY545 cells, and the LPA/1,25D-induced FGF23 synthesis was blocked by MEK1 inhibitor U0126. Our results indicate that LPA and 1,25D synergize in osteocytes to stimulate FGF23 production. The pathways mediating the effect of LPA/1,25D on FGF23 synthesis include MAPK and NF-KB signaling. These findings increase our knowledge of the mechanisms governing FGF23 synthesis and can lead to the discovery of new drug targets for treating FGF23-related disorders.

Overexpression of Nuclear Factor I-C (NFI-C) causes skeletal and growth defects in mouse.
*Dong-seol Lee[1], Joo-Cheol Park[2]. [1]School of Dentistry, Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea

Nuclear factor I-C (NFI-C) transcription factors are crucial regulators of various organ development and stem cell biology. Among their family, Nfic knockout mice show malformation in all mineralized tissues, but it remains unclear which stage of development Nfic is involved. We previously reported that Nfic induces the differentiation of ameloblast, odontoblast, and osteoblast. However, the question remains whether Nfic participates in skeletal development. Here, we demonstrate that NFI-C gain of function confirmed NFI-C did not cause abnormalities in skeletal formation during the fetal period but caused abnormalities in skeletal formation after birth. This study aimed to investigate the effect of the NFI-C gene, one of the factors regulating cartilage and bone development, on skeletal dysplasia during development. First, we constructed NFI-C-overexpressing transgenic mice using the prix1 promoter. It was observed that the mice overexpressed with the NFI-C gene at 5 days and 6 weeks were smaller than normal mice. In addition, the NFIC overexpressing mice showed short fingers or toes, especially the fourth and fifth fingers were short or underdeveloped, like Feingold's syndrome. It was also confirmed that mesenchymal-specific overexpression of NFI-C caused problems in limb development and calvarial bone formation, but ossification of the femur increased compared to wild-type mice. In addition, We investigated whether the expression levels of markers of bone and cartilage were altered in the Nfic-overexpressing mice at P1. The gene expression of Mycn-1, Sox6, TGF-?1, Fgf1, Fgf2, and FGFR2 was decreased in Nfic-overexpressing mice, whereas the expression of Sox9, Sox5, mir19 and mir92 was not altered. Therefore, it is thought that if the expression of the NFI-C gene can be appropriately controlled, it could be helpful to regenerate bone and cartilage damaged by various causes, including skeletal genetic diseases and osteoporosis. This work was supported by Basic Science Research Program through the Ministry of Education of the Republic of Korea and National Research Foundation (Grant No. No. NRF-2021R1A2C1095165).

A mechanosensor protein, Filamin A, mediated embryonic palate fusion through ?-catenin/Smad2: A bioinformatics-oriented study
*Ziyi Wang[1], Satoru Hayano[2], Yao Weng[3], Xindi Mu[3], Mitsuaki Ono[3], Toshi Oohashi[3], Hiroshi Kamioka[4]. [1]Okayama university, Japan, [2]Department of Orthodontics, Okayama University Hospital, Japan, [3]Department of Molecular Biology and Biochemistry, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan, [4]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sc, Japan

This study aimed to elucidate the key mechanisms and genes associated with cleft palate through a comprehensive bioinformatics analysis. By re-analyzing bulk RNA-seq data (GSE45568 and GSE185279) and conducting literature mining, we identified Filamin A (Flna) as a pivotal gene and Epithelial-Mesenchymal Transition (EMT) as a significant biological event in cleft palate development. Immunofluorescence analysis of in vivo embryonic palates revealed increased Flna expression in medial edge epithelial (MEE) cells and EMT cells within the epithelial triangle. In ex vivo cultured palates, various experimental interventions such as mechanical stimuli, a TGF-? inhibitor, and a RhoA inhibitor resulted in significant alterations in Flna expression. Flna, as a mechanosensor, is increased in response to mechanical stimuli on the ex vivo cultured embryonic palate. Through re-analysis of single-cell RNA-seq data (GSE155928), we newly identified an EMT cell cluster and observed a significant correlation between the expression of Flna and Ctnnb1. In the ex vivo cultured embryonic palate, the knock-down of Flna disrupted the palate fusion. Knockdown of Flna in both ex vivo cultured palates and HaCaT cells led to substantial changes in Ctnnb1/Smad2 expression. Additionally, our study consistently observed a correlation between Flna expression and MEE cell morphology in both in vivo and ex vivo cultured palates across all experimental conditions. These findings suggested that Flna may play a critical role in palate fusion by connecting mechanotransduction and the Wnt/TGF-?/Smad signaling pathways.

Collagen XII regulates cell migration required for regeneration and repair after Achilles tendon injury. *Yayoi Izu[1], kei Fujihara[1], Taiju Yoneda[1]. [1]Okayama University of Science, Japan

Achilles tendon injuries are common in athletes and the elderly. Because regeneration and repair of tendon is difficult due to poor vascularization and highly organized structure, resulting in clinical problems of re-tears and dysfunction after surgical reconstruction. Tendon regeneration and repair requires migration of tendon stem/ progenitor cells (TSPCs) at the site of injury. We previously demonstrated that collagen XII provides physical binding between adjacent tenocytes, thereby regulating tendon development and maintenance (Izu et al. Matrix Biol. 95:52-67. 2021). Here, we elucidate the role of collagen XII during tendon repair and regeneration by using Col12a1 null mice. Neonatal and adult mice are used as regeneration and repair models, respectively. The gait and the angle of plantar to floor analysis revealed that these were restored in wild-type mice by 2 weeks after injury, whereas Col12a1 deficient mice did not recover even 4 weeks after injury in regeneration model. Similarly, wild type repair model also showed not fully but functionally recover by 4 weeks after injury, whereas no recovery symptoms were observed in Col12a1 deficient mice. Histological analysis demonstrated an inflammatory response 3 days after injury in both genotype in regeneration model. By 2 weeks after injury, fiber like structure was found at the transection sites in wild type but not in Col12a1 deficient mice. To elucidate the cell migration ability of Col12a1 deficient cells, a wound healing assay was performed using primary tenocytes derived from neonatal FDL tendons. The results showed that the number of migratory cells were reduced in Col12a1 deficient compared to the wild type. Interestingly, the wild type tenocytes migrated toward the wounded sites, whereas Col12a1 deficient tenocytes migrated in disorganized fashion and lost directionality. Furthermore, the response to chemotaxis was analyzed by a transwell assay using TGF-b1, no genotype specific difference was observed. Collectively, our results suggest that collagen XII is involved in regulatory mechanisms of migration in TSPCs, tenocytes, and scar-forming fibroblasts in regeneration and repair. The function of collagen XII in cell-cell binding via matrix bridge formation suggests that this may be a novel mechanism for cell migration and/or guidance in tissue development and regeneration.

Unraveling the Cellular Activators of Osteoclastic Bone Resorption - The Key Role of Bone Surface Osteoprogenitors *Bilal M. El-Masri[1], Christina M. Andreasen[1], Xenia G. Borggaard[1], Viktoria B. Kofod[1], Malene H. Nielsen[1], Kaja S. Laursen[2], Jesper S. Thomsen[3], Anne Marie Brüel[3], Mads S. Sørensen[4], Lars J. Hansen[4], Michelle Macdonald[5], Julia F. Charles[6], Jean-Marie Delaisse[1], Thomas L. Andersen[1]. [1]Dept. of Clinical Research, University of Southern Denmark, Denmark, [2]Dept. of Forensic Medicine, Aarhus University, Denmark, [3]Dept. of Biomedicine, Aarhus University, Denmark, [4]Dept. of Otorhinolaryngology - Head and Neck Surgery and Audiology, Rigshospitalet, Denmark, [5]Healthy Ageing Theme, Garvan Institute of Medical Research, Australia, [6]Dept. of Orthopaedic Surgery, Brigham and Women's Hospital, Harvard Medical School, United States

The activation of osteoclastic bone resorption and its cellular orchestrators remain poorly characterized. We utilized highly sensitive in situ hybridization on human bone samples and rodent models as a direct approach to identify spatially the key cells that orchestrate the activation of osteoclastic bone resorption through the RANKL/OPG-pathway across skeletal sites, and during anti-RANKL treatment.The study demonstrates that RANKL is expressed mainly by bone surface osteoprogenitors (bone lining cells, reversal cells or canopy cells) and much less by osteocytes proximate to osteoclasts in human (3% vs 30%), rat, and mouse bone. Conversely OPG is expressed mainly by osteocytes and less by bone surface osteoprogenitors. The RANKL+ bone surface osteoprogenitor populations which proximate to osteoclasts also express MMP13, RUNX2, and DMP1 in humans and mice, and CD56, CD271 and PTHR1 in humans.As these osteoprogenitors, not osteocytes, are the most abundant Rankl+ Dmp1+ population in mice, we selectively knocked out Rankl in Dmp1+ cells using Dmp1-cre;Rankl-fl/fl mice. We validated that Cre was expressed by bone surface cells in these mice. μCT analysis of the distal femoral metaphysis revealed a significantly higher trabecular bone volume in 15-week-old male and female Cre+ compared to Cre- mice. RNA-based histomorphometry revealed a significant reduction in Col1a1high osteoblast surfaces in Cre+ compared to Cre- mice but surprisingly no change in Acp5+ osteoclast surfaces.In 7-week-old healthy female mice treated with OPG:Fc for 2 weeks, Rankl+ bone surface cells remained abundant, even though no Acp5+ osteoclasts were present. Interestingly, both the bone surface cells and osteocytes had a significantly increased Rankl/Opg expression ratio in OPG:Fc treated mice compared to vehicle, which may explain the rebound following anti-RANKL treatment discontinuation. On the other hand, at skeletal sites with an extremely high endogenous expression of Opg by fibrocytes, like the temporal bone of the inner ear of rats, we observed nearly no Rankl+ bone surface cells or osteocytes. This supports the concept of local regulation of RANKL expression by bone surface cells.Collectively, this study supports the concept that bone surface osteoprogenitors activate bone-resorbing osteoclasts through RANKL signaling in response to local (osteocytic) and systemic (e.g. PTH) signals and that they contribute to the rebound following anti-RANKL treatment discontinuation.

Identification of metaphyseal Nestin-GFPbright stromal cells as a skeletal stem cell subpopulation in growing trabecular bone *Shinichirou Ito[1], Toshihide Mizoguchi[1], Masataka Kasahara[2]. [1]Tokyo Dental College, Japan, [2]Tokyo Dental College, Department of Pharmacology, Japan

‹Objective›Two distinct types of Nestin (Nes)-GFP+ stromal cells in the bone marrow (BM) can be detected based on their GFP expression levels (Nature 502(7473):637, 2013). Nes-GFPdim cells are observed throughout BM and overlap with leptin receptor (LepR)+ skeletal stem cells (SSCs). In contrast, Nes-GFPbright cells localize to peri-arterial niches and the metaphysis, and arterial Nes-GFPbright cells are considered a hematopoietic stem cell niche. However, the skeletal role of the metaphyseal Nes-GFPbright (hereafter Met-Nes-GFPbright) cell population remains elusive. Herein, using a Cre/LoxP-based strategy, we assessed the fate of Met-Nes-GFPbright cells during bone growth.‹Methods and Results›To examine the relationship between Met-Nes-GFPbright cells and LepR+ SSCs, we analyzed bone tissue of LepR-creER;Rosa26-loxP-stop-loxP-tdTomato(R26-Tom);Nes-GFP mice labeled on postnatal day 14 (P14). After 48-h labeling, some LepR-creER-labeled cells were observed to overlap with Met-Nes-GFPbright cells, indicating that Met-Nes-GFPbright cells are a subpopulation of LepR+ SSCs. As induced Cre expression in Nes-creER mice was detectable only in Met-Nes-GFPbright cells, and not in Nes-GFPdim cells, this mouse line was applied for lineage-tracing analysis of Nes-creER/Tom cells labeled on P1. Significant increases in the absolute number of Nes-creER/Tom cells was observed by P9; however, most were lost by P57. We further examined the appearance of Nes-creER/Tom cells according to the growth stage of bone tissues, and found that the absolute number of these cells increased up to P14 labeling, and became almost undetectable at P56 labeling. To examine the role of Nes-creER/Tom cells, these cells were depleted using Nes-creER;R26-Tom;R26-diphteria toxin A (DTA) mice during bone growth (P6 to P12) and analyzed on P14. Micro-CT showed that the trabecular bone volume was significantly decreased by cell depletion. These results prompted us to investigate the potential of Nes-creER/Tom cells to differentiate into osteoblasts using Nes-creER;R26-Tom;type I collagen (Col1)(2.3 kb)-GFP mice. Lineage-tracing analysis revealed that Nes-creER/Tom cells labeled on P14 significantly contributed to Col1 (2.3 kb)-GFP+ mature osteoblasts after a 1-week chase.‹Conclusion›Based on the findings, Met-Nes-GFPbright cells are a subpopulation of skeletal stem cells that transiently contribute to trabecular bone growth via osteoblastic differentiation.

The Interrelationship of Supplemental Vitamin D and Vitamin K Status on Incident Fractures: Results from the VITamin D and OmegA-3 TriaL (VITAL) *Sharon Chou[1], Sarah Booth[2], Dana Ratnarajah[1], Nancy Cook[1], Gregory Kotler[1], Xueyan Fu[2], Julie Buring[1], JoAnn Manson[1], Meryl LeBoff[1]. [1]Brigham and Women's Hospital , United States. [2]Tufts University, United States

Vitamin D and vitamin K are both involved in bone metabolism. We recently reported in the VITamin D and OmegA-3 TriaL (VITAL) that daily supplemental vitamin D (2000 IU/d) vs. placebo did not reduce fracture risk in 25,871 U.S. men (aged >=50) and women (aged >=55) enrolled from 50 states.1 While vitamin D stimulates transcription and translation of osteocalcin (OC) and matrix Gla protein (MGP), vitamin K is needed to carboxylate and activate these proteins. Older adults have low vitamin K intakes, and it has been proposed that vitamin D effectiveness on bone health is attenuated by low vitamin K status. Currently, there are limited data on the interaction of vitamin D and vitamin K statuses and effects of supplemental vitamin D on fracture risk. In this VITAL ancillary study, we tested in a case-cohort sample of 1,162 participants with fractures and an age-sex-matched subcohort size of 2,652, whether baseline low vitamin K status modifies the effects of supplemental vitamin D on incident total, non-vertebral, and hip fractures. The mean (+/-SD) age of participants was 68.3+/-7.2 years and the mean BMI was 27.3+/-5.3 kg/m2. 60.6% of the case-cohort participants were female and 81.2% were Non-Hispanic White. Fractures were reported on annual questionnaires and adjudicated through medical record review. To assess vitamin K function, percent undercarboxylated osteocalcin (%ucOC) and dephosphorylated undercarboxylated MGP ([dp]ucMGP) were measured in fasting baseline blood samples. High levels of %ucOC and (dp)ucMGP indicate low vitamin K status. %ucOC was calculated from measures of ucOC and total OC. The ucOC, total OC and (dp)ucMGP, were measured by sandwich ELISAs (IDS-iSYS Multi-Discipline Automated System). The effects of supplemental vitamin D on total, nonvertebral, and hip fractures were not modified by baseline levels (above or below the median) of %ucOC and (dp)ucMGP (Table 1; hip fractures not shown due to low power). In the largest randomized controlled trial of supplemental vitamin D vs. placebo on fractures, low vitamin K status does not explain the lack of effect of vitamin D supplementation on fracture prevention. Ongoing analyses are examining whether low baseline vitamin K status in combination with low baseline vitamin D levels are associated with increased incident total, non-vertebral, and hip fractures in VITAL.1. LeBoff MS, et al. NEJM 2022

Correlation between 25OHD and age, body weight, BMI and season of the year in supplemented and not supplemented women *Jose L Mansur[1], María J Castro[2]. [1]Center of Endoc and Osteoporosis La Plata Argentina, Argentina. [2]Dept FisicoMatem, Fac Farmacia y Bioq, Univ Buenos Aires, Argentina

The 25OHD value of the population depends on several factors.Our objective was to analyze 25OHD levels in women and the relation between 25OHD with age, BMI, weight and season.Patients and methods: retrospective study of 25OHD in 730 women (528 without supplementation (not suppl) and 202 with supplementation (suppl) of 100.000 IU/month for more than 3 months). Data are shown as media +/- standard deviation, Spearman Rank Correation coefficient, Student Test, ANOVA with post hoc Tuket test, Test chi PearsonResultsNot suppl: Age: 52.8+/-14.6. BMI: 26.6+/-6.0 Weight: 68.6+/-16.1; 25OHD: 21.7+/-8.4Suppl Age: 63.4+/-11.3 BMI: 25.7+/-5.3 Weight:63.7+/-13.5; 25OHD: 44.5+/-10Suppl women were older (p<0,0001), and have less BMI (p=0.0113) and weight (p<0.0001)1. Age and 25OHNot Suppl: 65: 20.98+/-9.0Suppl 65: 45.6+/-11.7Younger women have less 25OHD in suppl.2. 25OHD and BMINot Suppl: 30: 18.2+/-7.5Suppl 30: 40.8+/-9.8Obese women have less 25OHD (not suppl and suppl)3. 25OHD in each season:Not Suppl: Winter: 18.1+/-6; Spring: 21.6+/-8; Summer: 26.6+/-9; Fall 24.1+/-9Suppl Winter: 43.9+/-10; Spring: 44.7+/-9; Summer: 49.1+/-11; Fall 43.2+/-13In not suppl winter is less than the other seasons, and spring is less than summer (Anova p<0.001). In suppl no diference.4. Association between 25OHD and BMI and WeightNot Suppl: BMI: p<0.0001 # Weight: p<0.0001 #Suppl: BMI: p=0.0135 # Weight: p<0.0001 #5. Association between 25OHD and BMI and Weight in each season:In not supplemented women 25OHD is associated with BMI and weight in Winter, Spring and Summer. In supplemented women 25OHD is associated with BMI and weight only in Winter.Discussion: We found that BMI and body weight have negative correlation with 25OHD in suppl and not suppl women. It is possible that body weight correlates better than BMI because the amount of body fat would be more important than BMI. In summer values are higher but with a mean lower than 30 ng/mL. Obese women have less 25OHD. The combination of obesity and winter has more risk of lower 25OHD. Younger women has less 25OHD in suppl women.We think that seems necessary detailing always the season of the year and whether it is obese or non-obese people in all the studies about 25OHD.

Comparative miRNA Profiling Reveals Differential Expression Patterns between SWR/J and TallyHo/JngJ Mouse Models *DAVID CARRO VAZQUEZ[1], Lejla Emini[2], Martina Rauner[3], Johannes Grillari[4], Lorenz Hofbauer[5], Matthias Hackl[6]. [1], Austria. [2]bone lab dresden, Germany. [3]Medical Faculty of the TU Dresden, Germany. [4]Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Austria. [5]TU Dresden University Medical Center, Germany. [6]TAMIRNA, Austria

Type 2 diabetes mellitus (T2DM) increases the susceptibility to bone fragility. We hypothesize that microRNAs could be involved in the underlying mechanism and be used as biomarkers for diagnosis of diabetic bone disease. To test this hypothesis, we aimed to detect dysregulated miRNAs using the polygenic murine model TallyHo/JngJ (TH), that recapitulates adolescent-onset T2DM in humans, as well as the recommended control SWR/J and a strain-matched non-diabetic control (TH-ND). RNA isolation and small RNA next generation sequencing (NGS) were performed for untargeted genome-wide miRNA analysis in serum, bone marrow and femora bone samples from all three groups. Metabolic and bone phenotype parameters were also determined in all animals. Significantly (Benjamini-Hochberg adjusted p<0.2) regulated miRNAs were further analyzed with miRnet 2.0 for miRNA~mRNA target network construction and with the FANTOM5 browser for their cell-type enrichment to identify putative donor cells. TH and TH-ND mice showed no differential bone phenotype and miRNA regulation. When comparing TH-ND with SWR/J mice, mmu-miR-351-5p and mmu-miR-322-3p appeared to be upregulated while mmu-miR-449a-5p and mmu-miR-6240 were downregulated in both bone marrow and serum. mmu-miR-6240 was downregulated while mmu-miR-1a-3p was upregulated in both femur tissue and serum. mmu-miR-196b-5p was downregulated in femur and upregulated in serum. Finally, mmu-miR-677-3p appeared to be downregulated in both bone marrow and femur. miRnet 2.0 analysis using these miRNAs revealed target genes such as Myc, Bcl2 and Gab1 which play roles in insulin secretion and Wnt, Ca2+ and Hippo signaling. FANTOM5 analysis showed that three of these miRNAs, hsa-miR-424-3p (homolog to mmu-322-3p), hsa-miR-1-3p and hsa-miR-196b-5p are highly expressed in mesenchymal stem cells or their derived cells such as skeletal muscle cells and osteoblasts. In conclusion, our comparative miRNA profiling sheds light on differential expression patterns between SWR/J and both subgroups of TallyHo/JngJ. There is no significant difference between the miRNA expression patterns of TH and TH-ND mice suggesting that the differential miRNA regulation observed in SWR/J mice may be due to its different genetical background. These findings contribute to the growing knowledge of bone complications associated with T2DM and emphasize the need for continued exploration using more representative animal models to advance our comprehension of this disease.

COMPENSATORY GAIT PATTERNS ARE RELATED TO SUBCHONDRAL BONE REMODELING IN RAT OA *Markia Bowe[1], Joshua Yarrow[1], Kyle Allen[1]. [1]University of Florida, United States

Pathologic subchondral bone modeling and/or remodeling are likely connected to abnormal movement patterns in OA. Here, subchondral bone plays an important role in joint function, working together with the articular cartilage to dissipate 30%-40% of the joint loads. Since abnormal loads may accompany changes in movement patterns, it is important to clarify how the relationship between altered movement and subchondral bone pathology is affected during disease progression. However, very few studies evaluate these pathologic subchondral bone changes within the context of mechanics. Furthermore, even fewer studies assess abnormal changes in movement and subchondral bone microstructure over multiple stages of disease progression. In this study, we evaluated the relationship between altered movement patterns and pathologic microstructural changes in subchondral bone in OA. 40 Lewis rats were split into groups of naïve rats and OA rats. OA was induced in one limb using two common models known to progress at different rates. Here, the medial meniscus transection (MMT) and medial collateral ligament transection (MCLT) models were treated as fast-progressing and slow-progressing OA models, respectively. At 2, 4, 8, and 12 weeks after OA induction, animals underwent gait testing and in vivo MicroCT imaging. Both MMT and MCLT rats had similar compensatory gaits, where OA animals spent more time on their operated and contralateral limbs throughout the experiment and had spatially and temporally symmetric gaits. Changes in subchondral bone microarchitecture were also similar across both groups. Cortical and trabecular thickness increased in OA rats, along with trabecular number and bone volume. More severe changes were seen in the subchondral bone of MMT rats, as expected. However, osteophytes only formed in MMT rats, presenting an important difference in pathologic bone structure between MMT and MCLT animals.

Doxorubicin induced senescence in the knee, a new mouse model to study degenerative arthritis *Vidyani Suryadevara[1], Mohammad Hajipour[1], Ariana Martin[2], Frezghi Habte[1], Noeen Malik[1], Edwin Chang[1], Dilyana Mangarova[1], Kerem Nernekli[1], Lucia Baratto[1], Lisa C. Adams[1], Jonathan Cotton[3], Bernd Pichler[3], Nicolas Be?zie?re[3], Heike Daldrup-Link[1]. [1]Stanford University, United States; [2]Meharry Medical College, United States; [3]Werner Siemens Imaging Center, Germany

Purpose: Senescence plays a key role in several mechanisms leading to osteoarthritis (OA), as evidenced by the amelioration of OA progression by senlolytic therapies. We developed a new mouse model to induce senescence using doxorubicin in the knee joints, which was further validated by PET-CT using a novel ?-galactosidase-based radiotracer, [18F]-PyGal.Methods: Senescence was induced by treating 20,000 primary chondrocytes with 400nM doxorubicin for five days, followed by the assessment of cell morphology, ?-galactosidase activity, and secretion of IL-6 and CXCL5. As approved by the animal care committee at Stanford, 12 mice aged 12-months (6 males, 6 females) received an intra-articular injection of 400nM doxorubicin in 50ul of PBS into the left knee. The right knee was injected with 50ul of PBS and served as the control (C). All mice underwent microCT (V=60 kV, I=167?A with rotation steps of 0.4°ß, 20u resolution), followed by intravenous injection of 250uCi [18F]-PyGal and positron emission tomography (PET). After imaging, the mice were sacrificed to collect knees for histological assessment of senescent markers using traditional ICC staining for p-16, p-21, and X-gal markers. Significant differences between the control and senescence groups were compared using t-tests.Results: Chondrocytes treated with doxorubicin had significantly elevated levels of IL6 (C: 18.39+/-5.10 pg/mL; S: 58.85+/-1.43pg/mL, p<0.005), CXCL5 (C: 153.8162+/-38.14pg/mL, S:1163.24+/-169.09pg/mL p<0.005) and beta-gal activity (C: 9.16+/-0.7%, S: 90+/-2%, p<0.0005). Senescent cells exhibited a 2.28-fold higher uptake of [18F]-PyGal than controls (C 1754+/-247.22, S 3704.23+/-570.76, p=0.005). Doxorubicin-treated left knees demonstrated significantly higher expression of p-16, p-21, and ?-gal markers than controls. MicroCT analysis revealed changes in the bone microarchitecture of doxorubicin-treated knees compared with control knees. In 12-month-old mice, significantly higher retention of [18F]-PyGal (0.47+/-0.18 %ID/g, 0.47+/-0.12 %ID/g) radiotracer in senescent knees was seen as compared to control knees (0.22+/-0.03%ID/g, 0.29+/-0.08, p=0.02, p=0.03 female and male respectively).Conclusions: Intra-articular doxorubicin administration as a preclinical model to induced senescence in the knee joints of mice. Senescent cells in doxorubicin-treated joints can be detected with [18F]-PyGal. This new model may be useful for studying the efficacy of senolytic therapy.

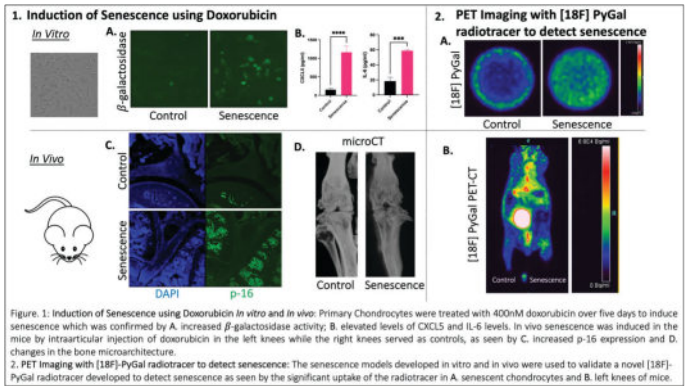

Figure. 1: Induction of Senescence using Doxorubicin *In vitro* and *In vivo*: Primary Chondrocytes were treated with 400nM doxorubicin over five days to induce senescence which was confirmed by A. increased β-galactosidase activity; B. elevated levels of CXCL5 and IL-6 levels. In vivo senescence was induced in the mice by intraarticular injection of doxorubicin in the left knees while the right knees served as controls, as seen by C. increased p-16 expression and D. changes in the bone microarchitecture.
2. PET Imaging with [18F]-PyGal radiotracer to detect senescence: The senescence models developed in vitro and in vivo were used to validate a novel [18F]-PyGal radiotracer developed to detect senescence as seen by the significant uptake of the radiotracer in A. senescent chondrocytes and B. left knees of mice.

LB SUN-625

Connecting HIPPO signaling to chromatin action during early osteoblast and adipocyte differentiation *Atenisa Caci[1], Alexander Rauch[1]. [1]1 Department of Clinical Research, University of Southern Denmark, Odense, Denmark; 2 Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark, Denmark

Background: Stromal cells of the bone marrow (BM-MSCs) give rise to osteoblasts, chondrocytes, and adipocytes. A network of about 200 transcription factors (including TEAD1) is pivotal for osteoblast, while efficiently inhibiting fat cell differentiation. YAP/TAZ have been previously recognized as pro-osteogenic and anti-adipogenic regulators, however, not through binding to TEAD1 but RUNX2 and PPAR-?, respectively.Purpose: Identify transcriptional mechanisms of the HIPPO signaling contributing to lineage commitment of BM-MSCs.Methods: TEAD1, RUNX2 and YAP1 binding, enhancer activity and gene expression profiles have been established during early in vitro differentiation of BM-MSCs using ChIP and RNA-seq. Quantification of Hippo signaling through YAP1/TAZ during BM-MSC differentiation using western blot and immunostaining and its impact on differentiation upon pharmacological inhibition or genetic knock down.Results: Genome-wide binding analysis confirmed YAP1 as a transcriptional coactivator in BM-MSC. Gain of YAP1 binding upon osteogenic stimulation was highly predictive for enhancer and gene activation, in contrast loss of YAP1 chromatin association marks enhancers that are deactivated upon adipogenic stimulation. Importantly, YAP1 binding dynamics show much stronger correlation with TEAD1 compared to RUNX2(ROC test pvalue:Ob up<2.2e-16,Ob down= 1.806e-13,Ad up<2.2e-16,Ad down<2.2e-16), indicating an unappreciated role of TEAD1 in BM-MSC differentiation (Figure1A). Immunostaining showed clear lineage selective dynamics in nuclear localization of YAP1(Cohen's estimation: 1dAdvsMsc= -0.1; 1dObvs0hMsc = 1.31(large)) (Figure1B) and reduction in nuclear YAP1 protein levels correlate with reduced genome-wide occupancy of both YAP1 and TEAD1 upon adipogenic stimulation, indicating cofactor-dependent dissociation. Besides controlling HIPPO target genes, YAP1 binding in cells exposed to osteogenic condition was associated with WNT-signaling, while loss of YAP1 binding upon adipogenic stimulation correlates with repression of those genes. Pharmacological inhibition and genetic ablation of YAP1 strongly reduces mineralization, with opposing effects on lipid droplet formation.Conclusion: From our genome wide binding pattern, we suggest TEAD1 as the major sequence specific rheostat of Hippo signaling that is implicated in lineage determination of BM-MSCs.

Inhibition of Dot1L histone methyltransferase activity promotes osteogenic differentiation *Alexander Tress[1], Drew Dauphinee[1], Alayna Grzybowski[1], Marta Stetsiv[1], Archana Sanjay[2], Rosa Guzzo[1]. [1]UConn Health, United States; [2]UCHC, United States

Posttranslational modifications of histones by chromatin modifying enzymes play a key role in determining transcriptional activity, making them attractive targets for skeletal repair and regeneration. Several histone methyltransferases are known to control bone formation. The Disruptor of telomeric-silencing 1-like (Dot1L) is the only known histone methyltransferase that catalyzes the di-methylation of lysine 79 in histone 3 (H3K79me2), a modification associated with gene expression. Our group previously demonstrated that loss of Dot1L expression in Prrx1+ mesenchymal progenitors impaired chondrocyte differentiation and endochondral bone growth in mice; however, the functional contribution of Dot1L to bone cell differentiation remained unexplored. Here, we examined the effects of Dot1L depletion, as well as the direct effects of Dot1L enzymatic inhibition on osteogenic differentiation in mouse mesenchymal stem/stromal cells and MC3T3-E1 osteoblasts. Mesenchymal stem/stromal cells harvested from the bone marrow (BM) of adult Dot1Lfl/flPrrx1Cre mice exhibited significantly higher numbers of colony forming units, with increased proliferative capacity relative to cells from Dot1Lfl/fl mice. Genetic depletion of Dot1L in BM derived mesenchymal stem/stromal cells resulted in increased levels of osteogenic genes (ie. Sp7, Ibsp, Osteocalcin), as well as elevated activity of alkaline phosphatase, and increased matrix mineralization relative to controls. Western blot analyses performed over a time course of osteogenic differentiation in mouse MC3T3-E1 cells showed significant down-regulation of H3K79me2 protein levels as compared to undifferentiated cells. Thus, we evaluated the impact of inactivating Dot1L methyltransferase activity in MC3T3-E1 cells by treating cells with a Dot1L-specific inhibitor under osteogenic conditions. Our results confirmed that inhibitor treatment accelerated osteogenic gene induction, and matrix mineralization in differentiating MC3T3-E1 osteoblasts. Results from the mouse cell line treated with the Dot1L inhibitor paralleled the effects of Dot1L protein loss in mouse primary mesenchymal stem/stromal cells. Taken together, our study indicates that Dot1L-H3K79me2 restricts osteogenic

differentiation, and that temporal inhibition of H3K79me2 may offer a novel approach for stimulating osteoblast differentiation.

Analysis of Runx2 transcriptional regulation by DNA methylation on DMR via Epigenome Editing *Yutaro Kawa[1], Jun Ohgane[2], Masafumi Inui[1]. [1]Laboratory of Animal Regeneration, Department of Life Sciences, School of Agriculture, Meiji University, Japan. [2]Laboratory of Genomic Function Engineering, Department of Life Sciences, School of Agriculture, Meiji University, Japan

Runx2 is a transcription factor essential for bone formation and its haploinsufficiency causes dysplasia of the skull and clavicle in mice and humans (known as cleidocranial dysplasia or CCD). Mutant mice with the Runx2 expression levels at 70% of that of wild type displayed abnormal skeletal development, demonstrating that a quantitatively precise level of Runx2 is essential for normal bone formation. Interestingly, identical twin CCD patients have reported phenotypic differences involving excessive teeth, suggesting that epigenetic mechanisms contribute to the quantitative regulation of Runx2. We hypothesize that transcriptional regulation by DNA methylation is involved in the process. Previous report have indicated the presence of a tissue-specific differentially methylated region (T-DMR) upstream of the transcriptional start site of Runx2-I in several mammals, and the methylation rate of this region inversely correlates with Runx2 expression during osteoblast differentiation. Therefore, in this study, our aim is to elucidate whether changes of DNA methylation level of this Runx2-I T-DMR could affect Runx2 expression using Cas9-based epigenome-editing tools. We designed guide RNAs targeting Runx2-I T-DMR, transfected them along with CRISPRoff-v2.1 into MC3T3-E1 cells, and found that the methylation level in the proximity of the gRNA target sites increased from 0%-10% to 20-30%. Furthermore, we increased the methylation level to 40-60% by optimizing the selection conditions of the transfected cells. Currently, we are examining whether this increase of methylation level could affect Runx2-I expression level as well as osteoblast differentiation process of MC3T3-E1 cells. In addition to the previously reported T-DMR, we are also examining the effect of this epigenome-editing on the activity of known and novel promoter/enhancer regions of Runx2. In this presentation, we will discuss the technical evaluation of epigenome-editing and the methylation variation in Runx2-I T-DMR, as well as its physiological function.

Peptidylarginine deiminase 2 plays a key role in osteogenesis by enhancing RUNX2 stability through citrullination *Hye-Rim SHIN[1], Hyun-Jung KIM[1], Heein Yoon[1], Min-Sang Park[1], Byung-Gyu Kim[2], Jae-I Moon[1], Woo-Jin Kim[1], Seung Gwa Park[1], Ki-Tae Kim[1], Ha-Neui Kim[3], Je-Yong Choi[4], Hyun-Mo Ryoo[1]. [1]Department of Molecular Genetics and Dental Pharmacology, School of Dentistry and Dental Research Institute, Seoul National University, Republic of Korea. [2]Center for Genomic Integrity, Institute for Basic Science (IBS), Republic of Korea. [3]University of Arkansas for Medical Sciences, Little Rock, United States. [4]Kyungpook National University, Republic of Korea

Peptidylarginine deiminase (PADI) 2 catalyzes the post-translational conversion of peptidyl-arginine to peptidyl-citrulline in a process called citrullination. However, the precise functions of PADI2 in bone formation and homeostasis remain unknown. In this study, our objective was to elucidate the function and regulatory mechanisms of PADI2 in bone formation employing global and osteoblast-specific Padi2 knockout mice. Our findings demonstrate that Padi2 deficiency leads to the loss of bone mass and results in a cleidocranial dysplasia (CCD) phenotype with delayed calvarial ossification and clavicular hypoplasia, due to impaired osteoblast differentiation. Mechanistically, Padi2 depletion significantly reduces RUNX2 levels, as PADI2-dependent stabilization of RUNX2 protected it from ubiquitin-proteasomal degradation. Furthermore, we discovered that PADI2 binds to RUNX2 and citrullinates it, and identified ten PADI2-induced citrullination sites on RUNX2 through high-resolution LC-MS/MS analysis. Among these ten citrullination sites, the R381 mutation in mouse RUNX2 isoform 1 considerably reduces RUNX2 levels, underscoring the critical role of citrullination at this residue in maintaining RUNX2 protein stability. In conclusion, these results indicate that PADI2 plays a distinct role in bone formation and osteoblast differentiation by safeguarding RUNX2 against proteasomal degradation. In addition, we demonstrate that the loss-of-function of PADI2 is associated with CCD, thereby providing a new target for the treatment of bone diseases.

Sorting Nexin 10 (SNX10) Limits Osteoclast Size by Arresting Cell Fusion in late Osteoclastogenesis *Maayan Barnea-Zohar[1], Nina Reuven[1], Sabina Winograd-Katz[1], Merle Stein[2], Sarah-Agnes Elkaim[1], Jan Tuckermann[2], Benjamin Geiger[1], Ari Elson[1]. [1]The Weizmann Institute of Science, Israel. [2]University of Ulm, Germany

Multi-nucleated osteoclasts (OCLs) are formed by regulated fusion of monocyte precursor cells that is induced by RANKL. Cell fusion is required for generation of active OCLs, but the extent of fusion is limited and OCL sizes typically fall within a finite and reproducible range. The mechanisms that arrest osteoclastogenic cell fusion and determine maximal OCL size are unknown. We show that the vesicular trafficking protein sorting nexin 10 (SNX10), whose loss induces autosomal recessive osteopetrosis, participates in regulating the maximal size of OCLs. Mice homozygous for the osteopetrosis-inducing R51Q mutation in SNX10 are massively osteopetrotic due to inactivity of their OCLs, which do not form ruffled borders. In culture, RANKL induces monocytes from these mice to fuse uncontrollably to generate OCLs whose sizes are up to 1000-fold larger than those of control OCLs, in the square millimeter range. Dramatically large OCLs are observed also ex vivo, when GFP-labelled OCLs are visualized in femurs and tibias of SNX10 mutant mice using two-photon microscopy combined with second harmonics generation microscopy. R51Q SNX10 OCLs exhibit reduced endocytosis, suggesting that their deregulated fusion is caused by disruption of physiological membrane homeostasis. The R51Q mutation destabilized the SNX10 protein, suggesting that loss of SNX10 deregulates OCL fusion. In agreement, we observed osteopetrosis, OCL inactivity, deregulated OCL fusion, and giant OCLs ex vivo also in SNX10-knockout mice. We conclude that OCL size is limited by an active, genetically-regulated, and OCL-cell autonomous mechanism that arrests cell fusion during osteoclastogenesis. This mechanism requires SNX10 but, surprisingly, this function of SNX10 is non-redundant, as disrupting this single protein deregulates cell fusion and abolishes control of OCL size.

Cholesterol sulfate inhibits osteoclast differentiation and survival by regulating the AMPK-Sirt1-NF-?B pathway *Jin Ha Park[1], Jiae Lee[1], Gong-Rak Lee[1], Hye In Lee[1], Minjeong Kwon[1], Hee Jin Kim[1], Mi-Ock Lee[2], Woojin Jeong[1]. [1]Department of Life Science and the Research Center for Cellular Homeostasis, Ewha Womans University, Republic of Korea. [2]ollege of Pharmacy and Bio-MAX Institute, Research Institute of Pharmaceutical Sciences, Seoul National University, Republic of Korea

Cholesterol sulfate (CS) is an activator of retinoic acid-related orphan receptor ? (ROR?). CS treatment or ROR? overexpression attenuates osteoclastogenesis in a collagen-induced arthritis mouse model. However, the mechanism by which CS and ROR? regulate osteoclast differentiation remains largely unknown. Thus, we aimed to investigate the role of CS and ROR? in osteoclastogenesis and their underlying mechanism. CS inhibited osteoclast differentiation, but ROR? deficiency did not affect osteoclast differentiation and CS-mediated inhibition of osteoclastogenesis. CS enhanced adenosine monophosphate-activated protein kinase (AMPK) phosphorylation and sirtuin1 (Sirt1) activity, leading to nuclear factor-?B (NF-?B) inhibition by decreasing acetylation at Lys310 of p65. The NF-?B inhibition was restored by AMPK inhibitor, but the effects of CS on AMPK and NF-?B were not altered by ROR? deficiency. CS also induced osteoclast apoptosis, which may be due to sustained AMPK activation and consequent NF-?B inhibition, and the effects of CS were significantly reversed by interleukin-1? treatment. Collectively, these results indicate that CS inhibits osteoclast differentiation and survival by suppressing NF-?B via the AMPK-Sirt1 axis in a ROR?-independent manner. Furthermore, CS protects against bone destruction in lipopolysaccharide- and ovariectomy-mediated bone loss mouse models, suggesting that CS is a useful therapeutic candidate for treating inflammation-induced bone diseases and postmenopausal osteoporosis.

Osteoclast-specific deletion of the beta 1-adrenergic receptor influences bone in mice, but does not rescue isoproterenol-induced bone resorption in vivo *Ryan Neilson[1], Claire Morrow[2], Daniel Brooks[3], Audrie Langlais[4], Karen Houseknecht[5], Christine Lary[6], Katherine Motyl[7]. [1]MHIR, United States. [2]Maine Health Institute for Research, United States. [3]BIDMC/MGH, . [4]MaineHealth Institute for Research, . [5]University of New England, United States. [6]Northeastern University, . [7]MaineHealth, United States

The sympathetic nervous system (SNS) promotes bone loss by suppressing bone formation and increasing RANKL-dependent osteoclast recruitment. Emerging evidence indicates the SNS may also work through beta-adrenergic receptor (?AR) activity directly in osteoclasts to promote bone resorption. Although ?1AR-selective antagonists may be more effective at reducing fracture risk and increasing bone mineral density clinically, no studies have examined the role of ?1AR specifically in bone resorption. To test the hypothesis that

SNS-mediated bone loss may work through ?1AR in osteoclasts, we generated an osteoclast-specific knockout of Adrb1 using the myeloid-lineage specific Lysozyme 2 promoter-driven Cre recombinase (a.k.a. LysM-Cre) model (Adrb1fl/flLyz2Cre/+). Efficiency of deletion was confirmed in primary osteoclasts and whole bone using qPCR. Consistent with our hypothesis, 16-week-old female Adrb1fl/flLyz2Cre/+ (Cre/+) mice had higher trabecular number (p=0.0297, n=10) and lower trabecular separation (p<0.0001, n=10/genotype), suggestive of slower trabecular bone loss as the mice aged from 8 to 16 weeks of age (compared to Adrb1fl/fl littermates). Consistent with this, in vitro bone resorption (CTX-1 levels in media from osteoclasts plated on bone chips) showed a trend towards reduction (by 54% (p=0.139, n=3)) despite a lack of changes in TRAP stain. However, in contrast to our hypothesis, male Adrb1fl/flLyz2Cre/+ mice did not exhibit a trabecular phenotype but had lower cortical area fraction (p=0.0179, n=10) at 8 weeks of age. To test if an osteoclast-specific deletion of Adrb1 would protect against SNS-mediated bone loss, we treated 8-week-old female Adrb1fl/flLyz2Cre/+ mice and Adrb1fl/fl littermates with isoproterenol (6 mg/kg) for 14 days. Both genotypes lost trabecular bone in a comparable manner, indicating that alone, Adrb1 in the osteoclast does not contribute significantly to SNS-induced bone loss. Importantly, ?2AR is more highly expressed in mice and humans, and ongoing studies in the lab are examining the effects of osteoclast specific ?2AR deletion, as well as conditional double knockout, since receptor compensation may occur. In summary, Adrb1 has a role in cortical acquisition in male mice and trabecular bone maintenance in female mice, but further studies are needed to determine the mechanism of bone loss prevention by ?1AR-selective antagonists.

Effect of change of the extracellular physical environment on differentiation of osteoclast precursors *Miho Ueta[1], Kazuki Takaoka[1], Hirokazu hattori[1], Tomoki Kakimoto[1], Sachiko Nosaka[1], Ayaka Hatanaka[1], Masayuki Oshitani[1], Kazuma Noguchi[1], Hiromitsu Kishimoto[1]. [1]Department of Oral and Maxillofacial Surgery, School of Medicine, Hyogo Medical University, Japan

[Introduction] Osteoclasts (OCs) are differentiated from monocyte/macrophage-lineage hematopoietic precursor cells which are termed OC precursors (OCPs) in the bone microenvironment. OCPs are drawn from the bloodstream to bone by various factors released at sites undergoing resorption in the bone microenvironment, and subsequently differentiate into OCs following stimulation with the RANK ligand (RANKL). The purpose of this study is to investigate the effect of change of the extracellular physical environment as from blood to bone on the differentiation of OCPs in the bone microenvironment. [Materials and Methods] RAW264.7 cells were used as osteoclast precursors, and cultured on either plastic cell culture dishes (solid condition as bone) or ultra-low attachment surface dishes (fluid condition as blood). We performed cell proliferation assay. After addition of RANKL, we counted the total numbers of cells with large multinucleated OC-like cells, and determined TRAP staining by TRAP solution kit (Oriental Yeast Co., Ltd., Japan). To perform immunohistochemistry, cells were collected using iPGell (GenoStaff, Japan), and stained with NFATc1. RANK, NFATc1, c-Fos and mTOR were detected by Western blot analysis. [Results] The cell proliferation of RAW264.7 cells increased under fluid condition compared with under solid condition. mTOR protein expression level under fluid condition were higher than under solid condition. On day 7, RANKL induced the formation of large multinucleated OC-like cells under solid condition, but failed to differentiate into OC-like cells under fluid condition. TRAP staining cells were significantly decreased under fluid condition, compared with under solid condition. Similarly, NFATc1 positive cells were lower under fluid condition compared with under solid condition by immunohistochemistry. RANK, c-Fos and NFATc1 protein expression levels under fluid condition were lower than under solid condition. [Conclusions] These results of this study indicate that the change of the extracellular physical environment (from fluid condition as blood to solid condition as bone) of OCPs may induce be one of the factors regulating that OCPs differentiate into OCs via up-regulated RANK.

Osteocyte single-cell ATAC sequencing shows genomic accessibility variations in mice with chronic kidney disease (CKD) *Mohammad Niroobakhsh[1], Xierzhatijiang Sulaiman[1], RAFIOU AGORO[1], Yamil Marambio[1], Dan Eaton[2], Magdalena Preciado López[2], Jun Wan[1], Kenneth White[1]. [1]Indiana University School of Medicine, United States. [2]Calico Life Sciences , United States

BackgroundOsteocyte malfunction is linked to common bone diseases such as aging, osteoporosis, and CKD, however it has been difficult to isolate cell-specific changes in vivo in models of these diseases. At the individual cellular level, understanding osteocyte genomic accessibility reprogramming is critical for identifying the contribution of osteocytes to the metabolic bone disease associated with CKD.MethodMale wild-type mice were placed on an adenine-containing or control diet (0.2%, n=5) for 4 weeks. Femurs, tibia, and humeri were collected and bone cells isolated using sequential digests of collagenase and EDTA. Following subtraction of marrow cells, sequencing libraries were prepared using the 10X Genomics protocol and single-cell ATAC sequencing (scATACseq) was carried out. Data processing and analysis included integration, filtering, dimension reduction, and differentially accessible region (DAR) analysis for enriched chromatin motifs. Osteocytes and osteoblasts were identified with chromatin accessibility encompassing their marker genes Dmp1, Phex, and Col1a1.ResultsTwenty-three distinct bone cell population clusters were identified by scATACseq, in which one cluster was identified as an osteocyte/osteoblast cluster which was 3% (147/4920) of the cells from the control group and 2% (165/8408) from the mice with CKD. In osteocyte/osteoblasts, based upon pathway analysis Dtwd1, Col12a1, and genes related to DNA metabolism, chromatin organization, and skeletal morphogenesis were significantly more open at promoter region peaks in CKD than controls. The up-regulated DARs were enriched with binding motifs for transcription factors Atf3, FosL2, and c-Jun. Pcdh17, Hpn, and genes related to cadherin binding and vasculogenesis were significantly more closed in CKD than in controls. The downregulated DARs in CKD osteocytes were enriched with motifs for SOX gene family members, suggesting unique cell- and disease-specific transcriptional regulation.ConclusionA novel workflow was developed to understand osteocyte genetic reprogramming profiles at the single-cell level. Genes involved in DNA metabolism, chromatin organization, and skeletal morphogenesis were found to be significantly more open in CKD osteocyte/osteoblasts whereas cadherin binding and vasculogenesis were significantly more closed. Thus CKD causes dynamic shifts in chromosomal accessibility which may help to predict skeletal outcomes and provide new therapeutic targets.

Motion artifact masquerading as femur fracture on DEXA: A case report *Maria Fariduddin[1], Subhash Kukreja[2], Michele Obeid[1], Kristen DeCarlo[3]. [1]University of Illinois at Chicago, United States. [2]University of Illinois, United States. [3]University of Illinois ,

A 41 y/o female with spastic quadriplegic cerebral palsy underwent a DEXA scan for osteoporosis screening. Femur image was read as atypical femur fracture based on transverse appearance on DEXA images. Further history revealed that the patient has no known diagnosis of osteoporosis, never been on bisphosphonates and is not on glucocorticoids. She is bed bound and non-weight bearing with no hip pain or history of hip trauma. Given the DEXA findings, bilateral hip X-rays were obtained which did not show any evidence of fracture. Atypical femur fractures (AFF) are defined as stress fractures occurring along the lateral shaft of the femur with minimal or no trauma. The major features which suggest this diagnosis include involvement of the subtrochanteric region and femoral shaft, transverse or short oblique orientation, medial spike in complete fractures, absence of comminution and no or minimal trauma. All the major features need to be present for a fracture to be designated as atypical. Minor features are cortical thickening and localized periosteal or endosteal thickening often referred to as “beaking” seen on imaging, presence of pain, bilateral occurrence, use of bisphosphonates or other antiresorptive agents, glucocorticoids or proton pump inhibitors. The DEXA in this case included all major features without any minor features. On close examination, a blurring of the upper femur was seen, suggesting that there may have been motion artifacts during the scan. The findings on the DEXA scan were determined to be secondary to rotation of the femur at the diaphysis giving an appearance of a femur shaft fracture caused by movement during the scan. This highlights the limitations of DEXA scan and how motion artifacts can lead to a false appearance of fracture which in turn can lead to unnecessary tests and patient anxiety. This emphasizes the importance of educating patients about lying still during the DEXA scan akin to CT imaging. However, this is challenging for patients with mental and physical impairments and raises the need to create a process of communication to the interpreting physician when there is excessive movement during the study in an effort to improve the accuracy of DEXA scan interpretation. This case illustrates that for the diagnosis of AFF, clinicians should carefully examine for typical findings of AFF and in the absence of these findings, should consider the possibility that the apparent fracture may reflect a motion artifact.

DXA-derived 3D Parameters of the Hip Discriminate Fragility Fractures in Patients with Axial Spondyloarthritis *Edgar Wiebe[1], Elisa Celine Schilling[2], Dörte Huscher[3], Andriko Palmowski[2], Zhivana Boyadzhieva[2], Sandra Hermann[2], Frank Buttgereit[2], Burkhard Muche[2]. [1]Charité Universitätsmedizin, Dept. Rheumatology , Germany. [2]Charité Universitätsmedizin, Dept. Rheumatology, Germany. [3]Charité Universitätsmedizin; Institute for Biometry and Clinical Epidemiology, Germany

Background: Axial Spondyloarthritis (axSpA) is related to osteoporosis and fragility fracture risk possibly not reflected by measurement of areal bone mineral density (aBMD) alone. DXA-derived three-dimensional (3D) analysis has emerged as a promising method for evaluating bone structural properties of the femur, showing good correlation with quantitative computed tomography, which has demonstrated good predictive capabilities for vertebral fractures in axSpA patients.Objective: Our objective was to investigate the discriminative performance of DXA-derived 3D parameters of the femur in comparison to aBMD and trabecular bone score (TBS) for pre-existent fragility fractures (FFx).Methods: This cross-sectional analysis is part of the Rh-GIOP prospective observational cohort study focusing on bone health in inflammatory rheumatic diseases. We analyzed baseline visits of axSpA patients fulfilling the ASAS 2009 classification criteria. Using 3D-Shaper software (v2.12, 3D-Shaper Medical, Barcelona, Spain), we derived various parameters (integral, trabecular and cortical volumetric BMD, cortical thickness and cortical surface BMD) from hip DXA scans. Logistic regression analysis was used to develop discrimination models incorporating DXA-based T-Scores, TBS, and 3D-Shaper parameters to detect pre-existent FFx in total, vertebral fractures (VFx), and non-vertebral fractures (NVFx). Area under the curve (AUC) with 95% confidence intervals were calculated.Results: 80 axSpA patients (64% male) were analyzed. The prevalence of FFx was 34%, with 15% having a history of VFx. DXA-T-Scores showed AUC values of 0.62 (0.48; 0.75), 0.54 (0.39; 0.70), and 0.64 (0.50; 0.78) for any FFx, VFx, and NVFx, respectively. DXA-derived 3D parameters exhibited better discrimination for fragility fractures, with AUC values of 0.75 (0.64; 0.86), 0.81 (0.69; 0.94), and 0.72 (0.59; 0.85). Incorporating these parameters in a logistic regression model with DXA and TBS further improved discriminative performance (any FFx: AUC 0.78 (0.67; 0.89), VFx: AUC 0.86 (0.74; 0.98), NVFx: AUC 0.75 (0.63; 0.88)). TBS alone or in combination with DXA did not enhance the discrimination of the model.Conclusion: Our results suggest that DXA-derived 3D hip parameters offer superior discrimination of pre-existent FFx compared to DXA or TBS alone in axSpA. Future longitudinal analysis will determine whether DXA-derived 3D measurements of the femur can improve fracture prediction in clinical practice.

Levels of Serum and Urine N-terminal Telopeptides of Type I Collagen (NTx) Correlate in Patients with Osteopenia *Dania Salih Bacha[1], Lea El-Hage[1], Kelly Brake[1], James Bena[2], Jessica Colon-Franco[3], Kevin M. Pantalone[1], Leila Zeinab Khan[1]. [1]Endocrinology and Metabolism Institute, Cleveland Clinic Foundation, Cleveland, Ohio, United States. [2]Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, Ohio, United States. [3]Pathology Institute, Cleveland Clinic Foundation, Cleveland, Ohio, United States

Purpose: Bone turnover markers (BTMs) are biomarkers released during bone remodeling. They have high utility in assessing responsiveness and adherence to osteoporosis treatment. One marker of bone resorption is N-terminal telopeptide of type I collagen (NTx) which is released from osteoclasts and can be measured in either serum or urine. Compared to serum NTx, urine NTx is impacted by both the circadian rhythm and the day-to-day variability in creatinine excretion, and it has to be collected from the second void of the day. This can be cumbersome for patients and clinicians. The primary purpose of this study is to measure the correlation between serum and urine NTx in patients with osteopenia not previously receiving anabolic or antiresorptive treatment for bone health.Methods: In this prospective, 6-month cohort study, 40 participants who met the study eligibility criteria and were diagnosed with osteopenia on Dual X-ray Absorptiometry (DXA) scan, were enrolled at Cleveland Clinic Foundation (CCF). Patient demographics and clinical characteristics were summarized. Participants were monitored with blood and urine testing at the time of enrollment and throughout the duration of the study. Lab tests were obtained exclusively at CCF laboratories. The urine samples were collected from the second void of the day and at the same time the blood samples were drawn. Spearman's correlation evaluated the association between urine and serum NTX levels. Graphically, the linear best fit model is shown.Results: The mean age of the cohort was 66.7 +/- 6.3 years, 95% were female, and 90% were Caucasian. All participants had an eGFR of at least 60 mL/min. The median (IQR) serum and urine NTx levels were 17.0 nmol bone collagen equivalents (BCE) [13.7, 20.6] (reference range: 6.2 - 19.0 nmol BCE), and 64.7 nmol BCE/nmol creatinine [42.5, 90.9] (reference range: 5.0 - 65.0 nmol BCE/nmol creatinine), respectively. A moderate correlation was observed between the urine and serum NTx levels (r value= 0.52, P-value<0.001, Fig.1). Conclusion: A moderate correlation between urine and serum NTx levels was observed. Since serum NTx has a smaller biological intrasubject variability, and is easier to obtain, compared to urine NTx, clinicians may consider using it interchangeably with urine NTx.

The validation of osteoporosis self-assessment tool for Asians using fracture probability according to BMI and age in Korean postmenopausal women : Ajou Bone Love Data *Bom-Taeck Kim[1], Junghwa Shin[2], Kwangyoon Kim[1], Sangmi Lee[3], Hanna Kim[4], Okyu Noh[5], Yoon-Sok Jung[6], Yong Jun Choi[6]. [1]Department of Family Practice & Community Health, Ajou University School of Medicine, Republic of Korea. [2]Department of Family Medicine, Korea University School of Medicine, Republic of Korea. [3]Pyeongtaeck Saint Mary's Hospital, Republic of Korea. [4]B&Viit Eye Center, Republic of Korea. [5]Department of Radiation Oncology, Ajou University School of Medicine, Republic of Korea. [6]Department of Endocrinology and Metabolism, Ajou University School of Medicine, Republic of Korea

Fracture probability in postmenopausal women depends on factors such as bone mineral density (BMD), body mass index (BMI), and age. The association of these factors with frac-

tures has been reported; however, the association of fracture probability with BMI and age was not assessed concurrently. Therefore, we investigated fracture risk according to different BMI and age groups in postmenopausal women. Medical records of 22,142 women aged >=50 years who underwent BMD measurement between January 2006 and December 2014 at Ajou university hospital were checked for exclusion criteria that are known to interfere with normal bone metabolism, such as thyroid illness, rheumatoid arthritis, and prescription of hormone replacement treatment. Overall, 6,503 women with baseline BMD were included, and their fracture records after BMD measurements were identified. They were categorized into seven age groups of 5-year interval (50-54, 55-59, 60-64, 65-69, 70-74, 75-79, and >= 80 years) and five BMI groups according to the Korean Society for the Study of Obesity Guideline: underweight (BMI < 18.5), normal (18.5 <= BMI < 23), overweight (23 <= BMI < 25), Obese I (25 <= BMI < 30), and Obese II&III (BMI >= 30). Women in each age and BMI group were investigated for T-score distribution and fracture incidence. The distribution of BMD for normal, osteopenia, and osteoporosis was 28.4%, 45.5%, and 26.1%, respectively. Osteoporosis prevalence was 53%, 27.7%, 24.7%, 23.5%, and 20.2% for underweight, normal, overweight, obese I, and obese II & III, respectively. Fracture rates were 10.3%, 6.3%, 7.2%, 8.4%, and 7.4% for underweight, normal, overweight, obese I, and obese II & III, respectively. Regardless of BMI, osteoporosis increased significantly with advancing age; however, fracture risk significantly increased only in women aged >=70 years (Table 1). Fracture risk did not follow the trend of osteoporosis when age and BMI were considered together. Underweight women were at increased risk of fracture from age 65 years. However, belonging to BMI groups other than underweight did not significantly increase fracture risk in older women, irrespective of BMD.

Table 1. Fracture rate (%) in BMI and age groups

	Underweight	Normal	Overweight	Obese I	Obese II&III	Total
50–54	2.7	3.7	5.7	5.0	2.9	4.4
55–59	13.6	6.2	6.0	8.3	4.9	6.8

Skeletal HR-pQCT Phenotypic Cluster Associations with Lower Leg Power in Older Men and Women: the Study of Muscle, Mobility and Aging (SOMMA) *Morgan Bolger[1], Kerri Freeland[3], Megan Marron[3], Nina Heilmann[3], Tong Yu[3], Lauren Roe[3], Nicole Sekel[3], Kristen Koltun[3], Katelyn Guerriere[4], Julie Hughes[5], Bradley Nindl[3], Ashley Weaver[6], Paolo Caserotti[7], Peggy Cawthon[8], Anne Newman[3], Jane A. Cauley[9], Elsa Strotmeyer[3, 1], [3]University of Pittsburgh, United States, [3]University of Pittsburgh, , [4]USARIEM, United States, [5]US Army Research Institute of Environmental Medicine, United States, [6]Wake Forest University School of Medicine, United States, [7]University of Southern Denmark, Denmark, [8]California Pacific Medical Center, United States, [9]UNIVERSITY OF PITTSBURGH, United States

The association between bone and muscle with age may be driven by mechanical loading and muscle-bone interactions. Skeletal phenotypic clusters were identified based on high-resolution peripheral quantitative computed tomography (HR-pQCT) scans of the distal tibia (DT) and distal radius (DR) of older men and women in the Study of Muscle, Mobility and Aging (SOMMA) at year 1. We hypothesized that the phenotypic clusters would differentially associate with muscle function measures including stair climb ascend power (Watts=W; best of 3 laps), single leg press peak power (W; 40-70% 1-RM) and strength (1-RM, kg), and maximum grip strength (kg). Fuzzy c-means clustering found 3 clusters using within-sex standardized z-scores for the HR-pQCT measures at separate sites, DT (N = 321; 76.3+/-4.7 years; 61% women; 87% white) and DR (N = 295; 76.1+/-4.5 years; 61% women; 87% white). For both sites, cluster 1 (C1) was high-total BMD (Tt.BMD), cortical area (Ct.Ar); cluster 2 (C2) was medium-Tt.BMD, Ct.Ar; and cluster 3 (C3) was low-Tt.BMD, Ct.Ar with higher trabecular area. No sex or race differences were found by cluster though men and women were analyzed separately in multivariate linear regression for muscle function. For women DTC3 was slightly older vs. DTC2, and DTC3 was taller with lower BMI vs. DTC2 & DTC1. For men, DTC3 was taller vs. DTC2 & DTC1, and weighed less vs. DTC2. For women, stair climb power was lower in DTC3 vs. DTC1. For men, DTC3 had lower leg power and leg strength vs. DTC1 (all p<0.05). At the DR site, no significant differences in any muscle function measure were observed between clusters for women or men. In linear regression models (Table 1, ref. C1) for women, DTC3 was associated with lower stair climb power, though not significant after adjusting for age, race, weight and height, and significantly associated (p<0.05) with lower leg press power after covariate adjustment. For men, DTC3 was associated with lower stair climb and leg press power and leg strength after covariate adjustment. No significant relationship was found between clusters and muscle function at the DR. These associations support the concept of bone phenotypic-specific associations with muscle function (power in women; power and strength in men) at the load-bearing DT site but not at the non-load bearing DR, highlighting relative the importance of mechanical loading to muscle-bone interactions.

Table 1. Standardized β regression coefficients of the distal tibia (DT) and distal radius (DR) categorical clusters (referenced vs. cluster 1; women DTC1=72; men DTC1=49; women DRC1=58; men DRC1=40) as predictors of sex-specific muscle function z-score (per SD for all) outcomes: stair climb power (Watts=W), leg press power (W), leg strength (kg), and grip strength (kg).

Global Prevalence of Osteoporosis in Rheumatoid Arthritis: Systematic Review and Meta-analysis *Khalid Almutairi[1], Johannes Nossent[1], David Preen[1], Helen Keen[1], Charles Inderjeeth[2], [1]The University of Western Australia, Australia, [2]University of Western Australia & North Metropoitan Health Service,

Background: Rheumatoid Arthritis (RA) patients have a higher risk of developing osteoporosis, which increases morbidity, mortality rates, and healthcare costs [1]. However, there is limited data on the prevalence of osteoporosis and associated risk factors in RA. Objective: Estimate the global prevalence of osteoporosis in RA patients, identify associated risk factors, and determine high-risk RA patients who require preventive osteoporosis treatment.Methods: We searched several databases (MEDLINE, Scopus, ProQuest Central, Web of Science, EMBASE, CINAHL, and Google Scholar) to estimate the global prevalence of osteoporosis in RA populations. We also evaluated the influence of geographical location, prevalence methods, and diagnostic criteria on prevalence estimates from 1980 to 2023.Results: We included 29 studies involving 31,473 RA patients with osteoporosis out of 130,989 RA populations. The global prevalence of osteoporosis in RA was estimated at 21.5% (95% confidence interval (CI) 16.5-27.0), with a prediction interval of 1.4% - 56.1% (Figure 1). The point-prevalence of osteoporosis was 19.2% (95% CI 13.3-25.8), while the period-prevalence was 27.1% (95% CI 18.9-36.3). The highest pooled prevalence of osteoporosis was observed in Asia (30.0%; 95% CI 22.1-38.6), while Europe (13.4%; 95% CI 8.9-18.7) and North America (13.3%; 95% CI 11.0-15.9) had lower estimates. Factors influencing osteoporosis prevalence included continents, prevalence methods, and diagnostic osteoporosis criteria. The World Health Organization (WHO) osteoporosis criteria exhibited greater consistency in prevalence estimates in RA populations, regardless of demographic characteristics.Conclusion: The estimated global point- and period-prevalence of osteoporosis in RA were 19.2% and 27.1%, respectively. Higher prevalence rates observed in Asia may be influenced by restricted healthcare access or variations in risk environments, highlighting the significance of the WHO criteria in predicting and guiding preventive treatment. Is poor glycemic control a risk factor for the development of Osteoporosis in Type 2 Diabetes Mellitus?: A Cross-Sectional Study *Jessica Margaux Mercado[1], Katrina Marie Mendoza[1], Jayrick Aguirre[1], Maria Jocelyn Isidro[1], Monica Therese Cating-Cabral[1]. [1]Makati Medical Center, Philippines

This study aimed to determine the relationship between poor glycemic control and the risk of osteoporosis in patients with Type 2 Diabetes Mellitus (T2DM) in a private tertiary hospital in the Philippines. The charts of 171 T2DM patients who underwent bone densitometry (BMD) were reviewed and the risk of osteoporosis was determined with the exposure of interest being poor glycemic control. Statistical analysis was performed via Wilcoxon-Mann-Whitney Test, Chi-square Test or Fischer's Exact Test, Simple logistic regression, Multiple logistic regression, and Stepwise Regression. From a study population of 171, 48 (28.07%) had osteoporosis. Poor glycemic control was not a risk factor in the development of Osteoporosis in patients with T2DM (OR 1.18, 95% CI 0.56-2.51). However it was seen that T2DM patients with older age had 1.08x odds of having osteoporosis (5% CI 1.01-1.16), and T2DM patients who have hypertension have 2.37x increased risk of developing osteoporosis (95% CI 1.05-5.36). Biguanide use among T2DM patients reduces risk of osteoporosis by 60% (95% CI 0.17-0.9). In conclusion, glycemic control did not present any association with the risk of developing Osteoporosis in Filipino patients with Type 2 Diabetes Mellitus. However, other coexisting factors such as increased age, presence of Hypertension and Biguanide use could be considered as independent risk factors for the development of Osteoporosis.

Lean Mass and Fat Mass Phenotypes in Association with Bone Mineral Density in Middle Aged Asian Chinese Women *Mya-Thway Tint[1], Li Ting Ang[2], Mabel Shu Fung Kouk[2], Melvin Khee Shing Leow[2], Seng Bin Ang[3], Kok Hian Tan[3], Shiao Yng Chan[4], Peter D Gluckman[5], Yap-Seng Chong[6], Keith M Godfrey[7], Nicholas Harvey[8], Cuilin Zhang[4], Johan G Eriksson[2]. [1]Agency for Science, Technology and Research, Singapore, [2]Singapore Institute for Clinical Sciences, A*STAR, Singapore, [3]KK Women's and Children's Hospital, Singapore, [4]Department of Obstetrics and Gynaecology, National University of Singapore, Singapore, [5]University of Auckland, New Zealand, [6]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [7]MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [8]University of Southampton,

BackgroundUntil recently, bone health research primarily focuses on osteoporosis and consequent fractures in older age. Women have lower bone mineral density (BMD) than men, hence they have higher incidence of osteoporotic fractures. Studies are sparse in younger populations, in whom early interventions optimizing bone health might be most beneficial. Lean mass (LM) and adiposity defined by higher BMI are known to be positively associated with BMD. To understand their differential contributions to bone health, this study examined the associations of LM, fat mass (FM), and LM-FM phenotypes with BMD in middle aged Asian Chinese women.MethodsA total of 272 Chinese women from the Growing Up in Singapore Towards healthy Outcomes (GUSTO) cohort underwent dual energy X-ray absorptiometry for measurements of LM, FM, and BMD at the femoral neck(FN), lumbar spine(LS) and total body(TB). Handgrip strength was also measured. Using multivariable linear regression analyses, we studied the associations between LM, FM and four LM-FM phenotypes based on dichotomized high vs. low LM and FM, and BMD. The cut-off for FM was 35%, the threshold proposed for prediction of metabolic syndrome among Chinese women, and for LM was appendicular LM index (ASMI), 5.4kg/m2 based on Asian Working Group for Sarcopenia guidelines.ResultsMean(SD) of age of women was 44(4) years. Percentages of women with osteopenia based on T-scores of BMD-FN, BMDLS, and BMDTB were 22.8%, 9.9% and 11.8%, respectively. 72.3% of women had FM>35%. LM was significantly and positively associated with BMD at all sites even after the adjustment for FM and age. FM by contrast was inversely associated with BMDTB. 18.6% of women had low LM and lower handgrip strength <18 kg-force, and 12.1% had low LM- high FM. Compared to women with high LM-low FM, women with low LM-low FM and low LM-high FM had lower BMD in all sites, while women with high LM-high FM had higher BMD possibly attributed to higher ASMI (Table1). Dose-response in these relationships was observed.ConclusionLM, but not FM, was significantly and positively associated with BMD in middle aged Asian Chinese women. Such findings highlight the need for earlier intervention well before osteoporosis develops. Women with low LM-high FM may be at heightened risk for sarcopenic adiposity later in life with consequent osteoporosis and metabolic diseases. Preserving or accruing LM while reducing adiposity is important for women's health over life span.

Denosumab improves bone mineral density and microarchitecture in patients with rheumatoid arthritis: randomized controlled trial by HR-pQCT *Ko Chiba[1], Naoki Iwamoto[2], Kounosuke Watanabe[2], Kazuteru Shiraishi[2], Atsushi Kawakami[2], Makoto Osaki[2]. [1]Nagasaki University Graduate School of Biomedical Sciences, Japan. [2]Nagasaki University, Japan

Introduction: This pre-specified exploratory analysis investigated the effect of denosumab on bone mineral density (BMD) and bone microarchitecture in patients with rheumatoid arthritis (RA) treated with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs).Materials and Methods: In this open-label, parallel-group study, patients were randomly assigned (1:1) to continuous treatment with csDMARDs plus denosumab or continuous treatment with csDMARD therapy alone for 12 months. BMD and bone microarchitecture were measured by dual-energy X-ray absorptiometry (DXA) and high-resolution peripheral quantitative computed tomography (HR-pQCT) (UMIN000030575 and jRCTs071180018).Results: Of 46 patients enrolled in the primary study, 43 were included in the full analysis set. The mean age was 65.3 years, 88.4% were female, and 60.5% had osteoporosis. Areal BMD of the lumbar spine increased from baseline to 6 and 12 months in both groups, but the increase was higher in the csDMARDs plus denosumab group. Areal BMD of the total hip and femoral neck increased from baseline to 6 and 12 months only in the csDMARDs plus denosumab group. Cortical volumetric BMD and cortical thickness of the distal tibia increased in the csDMARDs plus denosumab group at 6 and 12 months but decreased in the csDMARD therapy alone group. Trabecular bone parameters of the distal tibia improved only in the csDMARDs plus denosumab group at 12 months.Conclusion: Denosumab may be recommended for patients with RA treated with csDMARDs to increase BMD and improve bone microarchitecture.

Differences in long term bisphosphonate treatment between older adults in the United States and Canada *Kaleen Hayes[3], Sulbh Aggarwal[2], Michael Adegboye[3], Andrew Zullo[3], Sarah Berry[4], Arman Oganisian[3], Angela Cheung[5], Suzanne Cadarette[2]. [3]Brown University, . [2]University of Toronto, Canada. [3]Brown University, United States. [4]Hebrew SeniorLife/Beth Israel Deaconess Medical Center, United States. [5]University Health Network-University of Toronto, Canada

Background: Oral bisphosphonates (BP; alendronate, risedronate, ibandronate) are first-line therapy for osteoporosis (OP) in the US and Canada. Clinical guidelines recommend long-term treatment (>=3 years) with BP therapy to reduce fracture risk. Prior studies suggest that adherence to BPs is higher in Canada than in the US, yet there has been no direct comparison of long-term therapy between the two countries.Objectives: To describe and compare long-term BP use between the US and Canada.Methods: We leveraged claims data from: 1) a 20% random sample of Medicare Fee-for-Service beneficiaries (US cohort) and 2) universal healthcare administrative data from Ontario, Canada (ON cohort). In each cohort, we identified community-dwelling residents aged >=66 years newly initiating alendronate, risedronate, or ibandronate between 01/2008 and 12/2016. We excluded those with exposure to a non-OP-dosed BP or other OP medication in the 365 days prior to first oral BP use. We followed patients until 12/2019 to identify the proportion with >=3 years of BP use (proportion of days covered >=80%, using 3-year rolling windows) and Kaplan-Meier (KM) estimates for long-term use by the end of follow-up, censoring on death, insurance disenrollment, or end of data.Results: The US cohort comprised 518,781 individuals initiating oral BPs (88% female, mean age 78 [standard deviation (SD) 7.6] years, 76% alendronate; 5.4% with a prior major osteoporotic fracture [3.0% hip fracture]) and the ON cohort comprised 279,448 individuals initiating oral BPs (77% female, 37% alendronate, mean age 76 [SD 7.2] years), 8.9% with a prior fracture [3.6% hip fracture]). The prevalence of long-term BP therapy was lower in the US cohort (crude proportion: 17% [n= 86,379], KM estimate: 25%) vs. the ON cohort (crude proportion: 42% [n=116,907], KM estimate: 52%). Around 17% vs. 8% in the US and ON cohorts had only one oral BP prescription, respectively. The median length of long-term BP therapy was 4.0 (interquartile range [IQR] 2.3) years in the US cohort and 5.3 (IQR: 3.7) years in the ON cohort. Of those without long-term BP therapy, 6% in the US cohort vs. 17% in the ON cohort switched to another OP medication. Conclusions: The proportion of older adults with long-term BP therapy in ON is double that of US Medicare beneficiaries, but was low in both populations. Future research should explore the impact of lower BP exposure on fracture risk and identify strategies to promote long-term therapy.

Title: unexpected bone loss and new vertebral fractures after 1 year romosozumab. Teaching point: what are the most likely reasons for an unfavorable treatment response? *willem lems[1]. [1]amsterdamumc.nl, Netherlands

IntroductionRomosozumab is a new anabolic drug, in the FRAME and ARCH study, a large increase in BMD of spine and hips was found, and a reduction in fractures But what to do and how to interprete an unfavorable treatment response?Clinical CaseA 83-year old women presented after a fracture of the distal radius. Her medical history revealed chronic back pain and a family history of a hip fracture, no other risk facors for osteoporosis.At physical examnination her height was 159 cm (prior 168 cm), weight 55 kg. DXA/VFA showed osteoporosis of the lumbar spine and hips (T-scores -3.2 and -3.1 respectively) and vertebral fractures (T 12 Genant Grade 3, L1 Genant Grade 1). Blood tests, including bone markers, showed no evidence of secondary osteoporosis, and she was treated with romosozumab for one year. After 1 year, new vertebral fractures were detected (T 8 Genant Grade2, T 9 Genant Grade 3, L4 Genant Grade 1) and an increased collapse of L1 (now Grade 2). Moreover, we found a BMD loss of the hips of 7.6% and a mild increase of the BMD of the spine of 2.5%. Why did this patient show an unexpected and unfavorable response to romosozumab?1) Non adherence to therapy. However, our patient confirms that she has used all her medication, and we observed the classical pattern of changes in bone markers, with an early (transient) rise in P1NP and a mild decrease over time in CTX.2) A new comorbidity during the one year treatment with romosozumab, However, nor medical history nor physical eaxmination nor the lab tests (including PTH, paraproteins) revealed a new cause of secondary osteoporosis.3) Pretreament with antiresorptive drugs (which may lead to a blunted response). However, she was not pretreated with an antiresorptive drug.Clinical LessonAn unexpected and unfavorable treatment response may occur during romosozumab, in our patient probably a (bad) chance finding. Since the number of patients treated with romosozuamb is probably rising, it is important for clinicians to check in patients with an unfavorable response for nonadherence, new comorbidities and for pretreatment with antiresorptives as a possible explanation.

TITLE

Introduction:
Romosozumab is a new anabolic drug, in the FRAME and in the ARCH study, a large mean increase in BMD of the spine and of the hip and a reduction in incidence of vertebral fractures, compared to placebo and alendronate, was found. But what to do and how to interprete an unfavorable response?
Clinical case
An 83-year-old woman presented 3 months after a fracture of the distal radius.. History revealed chronic back pain. She reported a family history with a hip fracture, but no other risk factors for osteoporosis. At physical examination her height was 159 cm (prior 168 cm), weight 55 kg (body mass index 21.8 kg/m2). DXA/VFA showed eoporosis of the lumbar spine and total hip (T-scores respectively -3,2 and -3,1) and vertebral fractures (Th12 Genant Grade 3, L1 Genant Grade 1).Blood tests , including bone makers, showed no underlying cause of secondary osteoporosis, and she was treated with romosozumab for one year.
After 1 year treatment, new vertebral fractures were detected (Th8 Genant Grade 2, Th9 Genant grade 3, L4 Genant grade 1), increased collapse of fracture L1 (now Genant Grade 2) and a stable fracture of Th12 (Genant Grade 3), Moreover, we found a decrease in BMD of the hips of 7.6% and a mild increase of the BMD of the spine of 2.5%.

Why did this patient show the unexpected and unfavorable response to romosozumab?
1)Non adherence to therapy. However, our patient confirms that she has used all her medication, and we observed the classical the pattern of changes in bone markers, with an early rise after 2 months in P1NP and a decrease over time in CTX.
2)A new comorbidity during the one-year treatment with romosozumab. However, nor history nor physical examination (no loss of height) nor the repeated laboratory tests (including PTH, paraproteins) revealed a new cause of secondary osteoporosis.
3) Pretreatment with anti-resorptive osteoporotic drugs. However, this patient was not pre-treated with any antiresorptive drug.
Clinical Lesson
An unfavorable treatment response may occur during romosozumab, in our patient probably a (bad) chance finding. Since the number of patients treated with romosozumab is rising, it is important for clinicians to check for nonadherence, new comorbidities and for pretreatment with antiresorptives as a possible explanation.

RANKL inhibition creates a pro-osteoclastic environment, leading to an overshoot in serum TRAP and accelerated bone resorption following treatment withdrawal *Albert Kim[1], Ariel Castro-Martinez[2], Victoria Taylor[2], Suraj Dhakal[2], James Smith[2], Jacqueline Center[3], Christian Girgis[4], Peter Croucher[3], Michelle McDonald[5, 1], [2]Skeletal Diseases Program, Garvan Institute of Medical Research, Australia, [3]Garvan Institute of Medical Research, Australia, [4]Westmead Hospital , , [5]Skeletal Diseases Program, Garvan Institute of Medical Research, The University of Sydney, Australia

Cessation of denosumab (dmab) leads to a rapid loss in bone mineral density (BMD) due to accelerated bone resorption by osteoclasts. Optimal timing and approaches of sequential therapy have not yet been defined. This is likely due to a lack of understanding of the cellular mechanisms at play, and optimal serum turnover marker assessment. We sought to examine temporal changes in RANKL signalling and serum TRAP5b compared to typical bone turnover markers CTX and P1NP, to define alternative tools to guide sequential treatment. We also aimed to determine the role of osteoclast precursors in this bone loss.Seven-week-old female C57BL/6 mice were treated with 2-weeks of saline or thrice-weekly OPG:Fc (10mg/kg) to inhibit RANKL then withdrawn from therapy (OPG-W)). Longitudinal BMD and serum was measured throughout the study. Mice were harvested at weeks 2, 8, 11 and 13 to allow a large serum collection for concurrent measures of RANKL, TRAP5b, P1NP and CTX respectively and at week 8 bone samples assessed for RANKL mRNA. At week 6 bone marrow samples were analysed for osteoclast precursors defined as NK1.1- Ter119- CD3-Ly6G-, B220-, CD11blo, CD117int, CD115+.Following OPG:Fc withdrawal, BMD was increased 24% at week 8 in OPG-W mice ($p<0.01$), declining at week 10 and normalised to vehicle levels by week 13. Serum TRAP, CTX and P1NP were all suppressed in OPG-W treated mice to week 8 ($p<0.001$). An overshoot in serum TRAP occurred in OPG-W treated mice at week 11 ($p=0.01$), whereas serum P1NP and CTX remained equivalent to vehicle. By week 13, serum TRAP, P1NP and CTX were all significantly higher in OPG-W treated mice ($p<0.01$). Serum RANKL levels were elevated with OPG:Fc at week 2 ($p<0.001$), peaking 13 fold higher at week 8 ($p<0.0001$), returning to control levels by week 11. Bone surface RANKL mRNA was significantly elevated above vehicle at week 8 ($p<0.01$), prior to the overshoot in serum TRAP levels. At week 6, osteoclast precursors were elevated in bone marrow in OPG-W treated mice ($p<0.05$).We show that rebound decline in BMD has already occurred by the time bone turnover markers used in clinical practice (P1NP and CTX) rise above vehicle levels. A significant overshoot in serum TRAP occurs earlier and prior to bone loss and may better inform sequential therapy following dmab discontinuation. Prior to the rise in serum TRAP, RANKL levels are elevated in bone and serum, providing a pro-osteoclastogenic signal for accumulated osteoclast precursors..

First Oral hPTH(1-34) Tablet Treatment for Osteoporosis Demonstrates Rapid Pharmacodynamic Effect on Plasma Levels of Endogenous PTH(1-84) *Arthur C. Santora[2], Gregory Burshtein[2], Constantin Itin[2], Hillel Galitzer[2], Anke Hoppe[2], Chana Sternberg[3], Miranda Toledano[2], Yoseph Caraco[4, 2]Entera Bio, United States, [2]Entera Bio, Israel, [3]CSC Ltd, Israel, [4]Hadassah Medical Center, Israel

Introduction: Entera is developing EB613 [hPTH(1-34) tablets, EBP05] as the first oral anabolic therapy for the treatment of osteoporosis. In a 6-month, 161-patient, placebo-controlled Phase 2 study, EB613 produced rapid dose-proportional increases in biochemical markers of bone formation, reductions in markers of bone resorption, and increased lumbar spine, total hip, and femoral neck Bone Mineral Density (BMD) in postmenopausal women with low BMD or osteoporosis.A Phase 1 study comparing EB613, subcutaneous (SC) injection hPTH(1-34) 20 ?g (Forteo®) and a new generation of Entera's oral peptide delivery platform is ongoing. One of the objectives of this study is to rapidly evaluate the pharmacodynamic (PD) effects of our oral hPTH(1-34) tablets. An increase in plasma ionized calcium should result in decreased secretion and plasma concentrations of endogenous PTH(1-84). Thus, a reduction in plasma PTH(1-84) should provide an early PD marker indicating systemic exposure and pharmacologic activity with our oral hPTH(1-34) tablets.Methods: This Phase 1 open label, exploratory, cross-over study evaluating PK, PD and safety in healthy male volunteers is being conducted at Hadassah Medical Center, Israel. In the first phase of the study, EB613 (1.5 mg and 2.5 mg) tablets and SC injection Forteo® were administered in a randomized order to 15 subjects. Endogenous PTH(1-84) was measured with a intact PTH immunoassay as an early PD marker of the pharmacologic effect of the treatments.Results: Mean plasma PTH(1-84) levels following a single administration of both oral EB613 doses and Forteo® rapidly decreased in all subjects. EB613 showed comparable maximal decreases in levels of PTH(1-84) as Forteo®. Treatments were well tolerated, with safety consistent with previous studies.Conclusion: EB613 oral tablets rapidly decreased plasma concentrations of PTH(1-84) after a single dose. The early results available from this ongoing study indicate that plasma PTH(1-84) may serve as an early PD marker indicating systemic exposure and pharmacologic activity with our orally administered hPTH(1-34) tablets.

The Impact of Stopping Oral Bisphosphonates on Plasma Advanced Glycation End Products *Tatiane Vilaca[1], Fatma Gossiel[2], Casper Schalkwijk[3], Richard Eastell[1, 1]University of Sheffield, United Kingdom, [2]The University of Sheffield, United Kingdom, [3]Maastricht University Medical Center, Netherlands

Atypical femur fractures (AFFs) have been associated with the long-term use of bisphosphonates (BP), but the risk of these fractures decreases within the first year of stopping the treatment. The mechanism for this increased risk of AFF is unknown. Advanced glycation end products (AGEs) are the result of non-enzymatic reactions between sugars and macromolecules. The accumulation of AGEs compromises the bone matrix quality and affects bone material properties. Animal models have shown that high doses of bisphosphonates (BP) promote bone accumulation of AGEs; however, the effect of therapeutic doses of BP on circulating AGEs in humans is not known. We investigated the effects of the use and withdrawal of licenced doses of oral BP on serum levels of AGEs. We hypothesise that bisphosphonates would lead to an increase in serum levels of AGEs and that levels would decrease after stopping BP.We used ultra-performance liquid chromatography with tandem mass spectrometry to measure N?-carboxy-methyl-lysine (CML) and N?-carboxy-ethyl-lysine (CEL), and Methylglyoxal-derived hydroimidazolone (MG-H1), and high-performance liquid chromatography with fluorescent detection to measure pentosidine. We used automated immunoassays to measure the C-telopeptide of type I collagen (CTX) and intact pro-collagen I N-propeptide (PINP). We used samples from 48 postmenopausal women from the TRIO/TRIO offset study, who received oral BPs (alendronate 70mg weekly or risedronate 35 mg weekly or ibandronate 150 mg monthly) for 96 weeks and were followed for 96 weeks after stopping therapy. We measured AGEs and bone turnover markers at baseline, after 48 and 96 weeks of BP therapy, and after 48 and 96 weeks of BP discontinuation. We log transformed variables that were non-normally distributed and used mixed effect analysis to compare the several timepoints.The use of BPs did not affect levels of AGEs ($p>0.05$); however, after discontinuation, there was a decrease in CML (mean 9.3% p 0.05). In contrast, BP use led to a decrease in both CTX and PINP, followed by an increase after BP discontinuation without reaching baseline levels.Levels of AGES decreased after stopping BPs. This decrease was associated with an increase in bone turnover markers and could account for reducing the risk of AFF when stopping BP therapy.

KTA inhibits RANKL-induced Osteoclast Differentiation and Attenuates Lipopolysaccharide-induced Bone Loss in Mice *Saroj Kumar Shrestha[1], Se woong Kim[1], Yunjo Soh[1, 1]Jeonbuk National University, Republic of Korea

IntroductionInhibitors of osteoclast differentiation have been used to treat bone diseases. The current study aimed to demonstrate that kalkitoxin thiol amide (KTA), a marine product isolated from the marine cyanobacterium Moorena producens, could be a novel therapeutic for osteoclast-related diseases.Material and MethodsEffects of KTA on osteoclast differentiation were studied in TRAP+ multinucleated cells using M-CSF/RANKL-stimulating bone marrow cells. F-actin ring formation, pit formation assay, RT-PCR, western blot and ?CT were carried out to examine the effect of KTA on bone loss.ResultsKTA suppressed RANKL-mediated osteoclast differentiation and bone resorption activity in vitro and attenuated osteoclast-specific marker gene expression, including dendrocyte-expressed seven-transmembrane proteins (DC-STAMP), tartrate-resistant acid phosphatase, matrix metallopeptidase 2, and matrix metallopeptidase-9. Likewise, molecular analyses showed that KTA attenuated RANKL-mediated MAPK signaling pathways by inhibiting the phosphorylation of ERK1/2 and p38. KTA also suppressed MMP-2, MMP-9, cathepsin K, and c-fos protein expression. Furthermore, KTA inhibited LPS-induced osteolytic bone loss,

BMD (bone-marrow density), trabecular number (Tb. N), trabecular separation (Tb.S), bone volume/trabecular volume (BV/TV), and eroded surface/bone surface (ES/BS) ratios. KTA suppressed RANKL-induced osteoclastogenesis dose-dependently by reducing cathepsin K, ERK1/2, and p38 MAPK signaling pathways in vitro, thus preventing LPS-induced bone loss in vivo.ConclusionKTA significantly suppresses bone loss in-vitro and in-vivo, suggesting that KTA could effectively treat osteoclast-related bone diseases such as osteoporosis.

Evaluation of the bone mineral density and trabecular bone score in adults with X-linked hypophosphatemic rickets *Alberth Burnier[1], Macarena Jimenez[1], Danisa Ivanovic-Zuvic[2], Annette Madison[1], Pablo Florenzano[1]. [1]Endocrinology Department, School of Medicine. Pontificia Universidad Católica de Chile., Chile. [2]Endocrinology Section, Hospital del Salvador. Santiago, Chile. , Chile

X-linked hypophosphatemia (XLH), the most common cause of hereditary hypophosphatemia, manifests as rickets in children and osteomalacia in adults. Reports of bone mineral density (BMD) in this population have been discordant, with a trend toward higher BMD in the lumbar spine. There is limited data on trabecular bone score (TBS), whole body and forearm BMD measurements in these patients. Aim: To describe BMD and TBS inpatients with XLH, and to determine its association with clinical and biochemical phenotype. Method: Adult subjects with PHEX-confirmed XLH were included. All patients underwent lumbar spine, femoral neck, whole body and forearm GE/Lunar DEXA scans. Z-scores were defined compared to NHANES database. Clinical and biochemical data were obtained to determine its association with BMD. Results: Twenty-five adults were included, 18 (72%) women, median age of 35y (21-66). All patients were hypophosphatemic, 64% had elevated alkaline phosphatase and 52% had secondary hyperparathyroidism. Mean BMD at lumbar spine and the whole body was 1.405 gr/cm2 (Z-score: 2.1) and 1.190 gr/cm2 (Z-score: 1.1), respectively, both significantly higher than normal range ($p<0.05$). Mean BMD at the radius 33% was 0.596 gr/cm2 (Z-score: -1.7) , and 0.362 gr/cm2 (Z score: -0,5) at the ultra-distal radius, both significantly lower than the norm-based population ($p<0.05$). Mean TBS was 1.519 with a mean Z-score of 1.43, significantly higher than the normal population ($p<0.05$). Mean BMD at the femoral neck was 0.888 gr/cm2 (Z-score: -0.7). The rate of exposure to conventional treatment was negatively correlated with the whole body BMD ($p=0.009$, $r=-0.6$) and lumbar spine BMD ($p=0.02$, $r=-0.53$). Other clinical and biochemical parameters, such as alkaline phosphatase, PTH, vitamin D or FGF23 did not significantly correlate with BMD at any sites. Conclusions: Our population presents with higher lumbar spine BMD, whole body BMD and TBS compared to reference data, and lower BMD at the 33% and ultra-distal radius. Exposure to treatment is associated to lower BMD in the whole body and lumbar spine BMD. These findings suggest that the increased BMD at the spine could not only be explained by paraspinal calcifications, and that appropriate conventional treatment could have an impact on the high spine BMD phenotype of subjects with XLH.

Effect of Burosumab on Growth Trends in Patients with X-Linked Hypophosphatemia *Thomas Carpenter[1], Leanne Ward[2], Suzanne Jan De Beur[3], Hamilton Cassinelli[4], Erik Imel[5], Jill Simmons[6], Anna Ryabets-Lienhard[7], Jerry Li[8], Eric Chen[9], Antonio Ramirez[9]. [1]Yale University School of Medicine, United States. [2]Children s Hospital of Eastern Ontario, Canada. [3]Johns Hopkins University, United States. [4]CEDIE, Centros de Investigaciones Endocrinologicas Dr Cesar Bergada, Division de Endocrinologia, Hospital de Niños Ricardo Gutierrez, Argentina. [5]Indiana University School of Medicine, United States. [6]Vanderbilt University Medical Center, United States. [7]Children's Hospital Los Angeles , . [8]Kyowa Kirin, . [9]Ultragenyx Pharmaceutical Inc., United States

X-linked hypophosphatemia (XLH) is a rare, musculoskeletal disorder due to PHEX pathogenic variants characterized by rickets/osteomalacia leading to bone pain, skeletal deformities, and short stature. This initial analysis explores growth patterns in patients treated with burosumab from the XLH Disease Monitoring Program (DMP; NCT03651505) supplemented with data from prior XLH studies via DataLink, a compilation of clinical trial data.To assess the impact of XLH on age-dependent growth velocity, we explored records of patients (regardless of burosumab treatment) aged <25 years at entry into the DMP or other XLH studies with Center for Disease Control (CDC) reference values. We then examined height Z-score by age in the study population regardless of burosumab status. To assess the impact of burosumab, changes in height Z-score from first burosumab dose or observation (burosumab-naïve) were examined separately by duration of treatment or observation. Records represent study visits by treatment status; patients may have multiple records by age. Data are presented based on availability of endpoints for each record.As of June 2023, data were available from 592 patients aged <25 years at study entry. Mean CDC reference growth velocity peaked at age 13 years in males and 11 in females. In patients with XLH (burosumab-naïve and treated combined), mean growth velocity peaked at age 15 years in males and 12 in females, remaining above CDC values through age 18 when growth stopped in both cohorts.At the last record of each patient (burosumab-naïve and burosumab-treated combined), a downward trend in absolute height Z-score was seen from age 1 (n=17 records; mean (SD) -1.0 [1.7]) to age 8 years (n=44 records; mean [SD] -1.7 [1.4]). After age 8, mean height Z-scores stabilized (range of means [SD] -1.6 [1.1] to -2.1 [1.2]) through age 18.Height Z score changes from baseline in treated and burosumab-naïve patients age <8 were compared by duration of treatment/observation at each record date (Figure 1). Over the first 3 years, height Z-score decreased in burosumab-naïve patients and remained constant in treated patients ($p<0.001$).XLH is associated with growth delays, with the greatest delays in the first 8 years of life. Available study data in a limited population suggest burosumab treatment in this period may mitigate early negative impacts of XLH on growth velocity. Future analyses will explore its effect on final height.

LB SUN-651

(Towards Establishing Clinically Useful Treatment Guidelines for ERT in HPP Patients) Understanding the Impact of Discontinuing Enzyme Replacement Therapy in Adult Patients with Hypophosphatasia *Kathryn Dahir[1], Scout Dahir[2], Margo Black[1], Emery Mason Campbell[1], Cheryl Rockman-Greenberg[3]. [1]Vanderbilt University Medical Center, United States. [2]Vanderbilt University, United States. [3]Max Rady College of Medicine, Rady Faculty of Health Sciences, University of Manitoba, Canada

Hypophosphatasia (HPP) is a rare, genetic disorder caused by loss-of-function mutations in the ALPL gene. Disease presentation is variable, including skeletal, non-skeletal rheumatologic and neurological manifestations. HPP has no cure, but the advent of enzyme replacement therapy (ERT) has resulted in sustained improvement of disease burden. However, in the real-world, clinical practice setting, some patients discontinue ERT therapy due to perceived lack-of-benefit, side effects or restricted access. To anticipate and improve management of patients who discontinue ERT, comprehensive treatment guidelines are required that better identify these subgroups. The data regarding discontinuation of ERT in adults is limited to a published case series of 6 highly affected Canadian patients who lost access to ERT. Reasons for discontinuation of ERT in less affected individuals are unknown. The current study was based on the hypothesis that, in contrast to the Canadian cohort, cohorts at the Nashville site who discontinued asfotase alfa ERT (StrensiqTM) manifest different disease burden and characteristics. To test this hypothesis, the clinical characteristics of 39 HPP patients were recorded prior to treatment and the patients then longitudinally followed in an ongoing study: 10.3% (n=4) electively stopped ERT due to perceived lack of efficacy, 28.2% (n=11) stopped ERT due to adverse events (hypersensitivity or injection side reactions), 5.1% (n=2) lost access to ERT, and 56.4% (n=22) continued ERT. Patients who electively stopped ERT were all female, had lower body mass index, and started ERT later in life compared to patients continuing ERT. Further, these 4 patients who electively stopped ERT experienced at baseline fewer musculoskeletal complications, including osteoarthritis (-69.4%), joint stiffness (-45.0%), fractures (-33.6%), and increased mobility (+16.6%) when compared to 2 patients stopping ERT due to adverse events. In contrast, fatigue and neurological complications of headaches and abnormal balance were the predominant disease features of those 4 patients who electively stopped ERT. All patients with adverse events or restricted ERT access suffered from high disease burden, thus making it important to devise sustainable treatment guidelines and access for these patients. These observations show that discrete disease burden may inform on ERT adherence and may aid in the development of effective, safe, and individualized ERT guidelines.

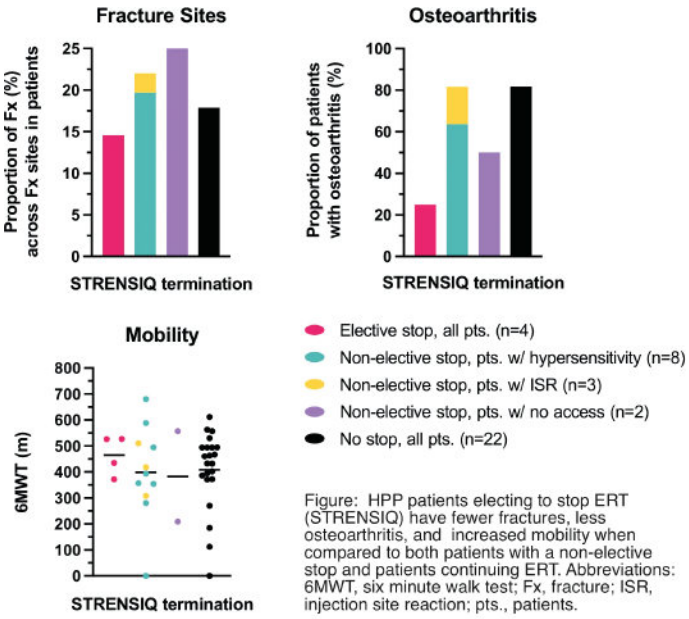

Figure: HPP patients electing to stop ERT (STRENSIQ) have fewer fractures, less osteoarthritis, and increased mobility when compared to both patients with a non-elective stop and patients continuing ERT. Abbreviations: 6MWT, six minute walk test; Fx, fracture; ISR, injection site reaction; pts., patients.

Eneboparatide, A Novel Investigational PTH1R Agonist, Maintains Calcium Homeostasis Without Deleterious Effects on Bone *Mark Sumeray[2], Michel Ovize[2], Soraya Allas[2], Guillaume Ravel[2], Myriam Aouadi[2], Michael Culler[2]. [2]Amolyt Pharma, France. [2]Amolyt Pharma, United States

Eneboparatide (EBO) is a novel PTH type 1 receptor (PTH1R) agonist with a short half-life and high affinity for the R0 receptor conformation. This profile is expected to result in maintenance of serum calcium (sCa) in chronic hypoparathyroidism (cHP) by recycling Ca from the glomerular filtrate and enhanced intestinal Ca absorption while avoiding the net bone resorptive effects of continuous PTH1R exposure. To explore this, data were examined from studies in non-human primates (NHP), healthy human volunteers (HV) and patients with cHP. NHP received daily sc EBO injections for 39 weeks at doses within and above the anticipated human therapeutic dose range. In HV, EBO was administered up to 80 µg/day for 2 weeks. In a phase 2 study cHP patients received sc EBO administration for 3 months starting at 10 or 20 ?g/day. sCa, 1,25 dihydroxy vitamin D (1,25 OH Vit D), bone biomarkers, and 24h urinary Ca (uCa) were measured in HV and patients. Bone mineral density (BMD) was measured in cHP patients by dual-energy X-ray absorptiometry. In NHP, BMD was measured by quantitative computed tomography, and bone histology was evaluated. In NHP, BMD, bone structure and turnover markers remained unchanged over 39 weeks. In HV there were no changes in bone biomarkers. In cHP patients, EBO had no significant effect on BMD and induced a modest, balanced increase in bone biomarkers (CTX and P1NP), consistent with resumption of physiologic bone turnover. Bone biomarkers and sCa levels were not correlated. In HV there was no increase in uCa despite marked elevation of sCa at higher doses of EBO. In cHP patients with hypercalciuria at baseline, uCa excretion was correlated with sCa levels. EBO treatment normalized uCa which was no longer correlated with sCa levels. Despite withdrawal of active Vit D supplements, EBO treatment maintained stable, normal levels of 1,25 OH Vit D. The collective data from NHP, HV and cHP patients indicate that EBO does not induce net bone loss. Further, treatment of HV with EBO maintains renal capacity to reabsorb Ca as sCa increases, while in cHP patients, EBO restores normal renal Ca reabsorption. EBO stimulated renal conversion of 25-0H to 1,25-0H Vit D allows continued intestinal Ca absorption despite the removal of supplements. These data suggest that restoration of Ca homeostasis with EBO in cHP is likely due to a sustained effect on renal Ca reabsorption and intestinal Ca uptake without deleterious effects on bone.

Injury-induced and Spontaneous Heterotopic Ossification in a New Acvr1 R206H Mouse Model for FOP *Salin A. Chakkalakal[1], Douglas W. Roberts[1], Jeffrey Xi[1], Maurizio Pacifici[2], Eileen M. Shore[1]. [1]Perelman School of Medicine, University of Pennsylvania , United States. [2]The Children's Hospital of Philadelphia, United States

Fibrodysplasia ossificans progressiva (FOP) is a rare disorder of heterotopic endochondral ossification (HO). In FOP, HO occurs in the absence or in response to tissue injury. Most patients with FOP share a heterozygous single nucleotide substitution (c.617G>A; R206H) in ACVR1 that encodes the bone morphogenetic protein type I receptor ALK2. A conditional Acvr1R206H/+ knock-in mouse (Acvr1[R206H]FlEx/+) was previously created to investigate disease pathogenesis. Once induced, the Acvr1R206H-expressing mice formed HO in response to injury. However the engineered allele in this model is null for Acvr1 prior to Cre-recombination, a possible complication. We developed an alternative knock-in mouse (Acvr1ARC-R206H/+) in which the engineered allele expresses wild-type R206 Acvr1 prior to Cre recombination and R206H following Cre. Here, we characterize the HO phenotype of this new model. Using our established approach for injury-induced HO, Acvr1R206H expression was activated globally via rt-tetO-Cre and leg skeletal muscle was then injured by cardiotoxin (ctx). Progression to HO was examined by histology and HO volume quantified by microCT over 2 weeks post-injury. Previously defined histologic stages of HO progression and altered muscle repair were identified, but with more robust chondrogenesis (5 dpi) and an apparent slower transition from cartilage to bone. We used the same rt-tetO-Cre system to examine 'spontaneous' HO progression in the absence of ctx injury. We found that HO developed more slowly than in response to ctx tissue injury. Little HO was detected by microCT at 3 weeks, but consistently formed by 4 weeks. Upon specific expression of Acvr1R206H in skeletal mesenchymal progenitor cells (Acvr1ARC-R206H/+;Prrx1-Cre), no extra bone was detected during embryogenesis; however at birth, development effects were indicated by reduced body length, malformed limbs with webbed digits, fused joints, and spine and skull malformations. Within 2 weeks after birth, spontaneous HO occurred that was more robust and rapidly progressive than that induced by global Cre induction, supporting the importance of cell interactions to regulate cell fate. Overall, our new FOP mouse shows more robust phenotypes than a previously described model. It is the first model for global induction of spontaneous (non-injury-induced) HO, providing a novel, patient-relevant system to investigate the initiation, progression, and cell mechanisms that regulate heterotopic ossification.

A Cell Culture Model Suggests a Key Function for Paracrine Signaling in the Development of Bone Fibrous Dysplasia *Amin Cressman[1], David Morales[1], Zhenyang Zhang[1], Fernando Fierro[1], Rakel Runarsdottir[1]. [1]Stem Cell Program, University of California Davis, United States

Fibrous Dysplasia/McCune Albright Syndrome (FD/MAS) is a rare disease caused by gain-of-function mutations in the gene coding for Gsalpha protein. We modelled the disease in a dish by modifying human bone marrow derived multipotent stromal cells (MSCs) to over-express either wild type Gsa or mutant Gsa (R201C and R201H). As additional control, MSCs were transduced with a lentivirus without over-expression of Gsa. MSCs expressing mutant Gsa (R201C or R201H), but not wild-type Gsa, show significantly higher levels of cAMP, impaired cell motility, and marked morphological changes that resemble excess RhoA signaling. Mutant Gsa also significantly inhibits osteogenic differentiation, measured by alkaline phosphatase activity at day 10 and mineralization (Alizarin Red S staining) at day 21. Interestingly, MSCs expressing mutant Gsa show decreased cell proliferation, but co-cultures with unmodified MSCs show increased cell growth as compared to controls. Even more, treatment of unmodified MSCs with supernatants derived from modified cells suggests that MSCs expressing mutant Gsa release signals that induce cell proliferation. Finally, we show that these supernatants induce activation of the canonical Wnt pathway on unmodified cells. A proteomic analysis of these supernatants lists a number of potential candidates driving this paracrine signaling. Our findings shed new light on the mechanism by which mutant Gsa may cause FD/MAS phenotype and offers a new platform to test potential therapeutic interventions.

Sexual Dimorphism in Treatment Effect of Anti-Siglec 15 in Adult Mice with Moderate-to-Severe Osteogenesis Imperfecta *Ketsia Seide[1], Holly LoTurco[1], Erin Carter[1], Nancy Pleshko[2], Priyanka Kothari[3], Sol Langermann[3], Shanmugam Selvam[3], Cathleen Raggio[4]. [1]Hospital for Special Surgery, United States. [2]Temple University, United States. [3]Nextcure, Inc., United States. [4]HSS, United States

Purpose: Osteogenesis imperfecta (OI) is a heterogeneous type 1 collagenopathy characterized by bone fragility. Gaps persist for effective pharmacological treatment in adult patients. We previously demonstrated that a monoclonal antibody targeting the sialic acid-binding immunoglobulin-like lectin 15 (Siglec 15) immunoreceptor [1], NP159 (NextCure), improves bone quality and decreases fractures in female oim mice. We have now extended the study to evaluate efficacy in male oim mice. Methods: In this portion of the study, eighty male mice (20 wildtype (WT) saline, 20 WT NP159, 20 oim/oim saline, and 20 oim/oim NP159) were treated from age 14 -26 weeks with either NP159 (10mg/kg weekly x1 month then biweekly) or weekly saline. Faxitrons at 14 and 26 weeks were taken to evaluate fracture incidence and healing. Tibias and femurs were analyzed post-sacrifice for femoral length, microcomputed tomography (micro-CT) , biomechanical testing and Fourier Transform Infrared Spectroscopy (FTIR). These results were compared to a previous study completed with female mice.Results: With treatment, 90% of male oim/oim NP159 vs. 85% of female oim/oim NP159 seen earlier, had no new fractures. Micro-CT showed decreased trabecular separation with NP159 treatment in both oim/oim males and females (p=0.05). Cortical porosity was normal in the male mice treated with NP159, in contrast with females

who showed increased porosity. There were no changes in the bone mineral density for male or female mice. NP159 increased stiffness of the bones in both sexes. FTIR in females showed a normalization of mineral:matrix ratio, increased acid phosphate and decreased collagen maturity. In contrast, the males showed no similar changes. Conclusion: Overall the results show promising trends for the use of NP159 treatment for OI. Fracture incidence was reduced. Sexual dimorphism was seen with treatment and is consistent with dimorphism both in humans and previously reported treated mice models. The observed cortical and trabecular bone changes support the premise that NP159 works as both an antiresorptive and a bone formation agent, and seems to be favorable for bone strength in both sexes as indicated by the increased stiffness shown on biomechanical testing. References 1. Sato, D., Takahata, M., … Iwasaki, N. Bone 2018; 116, 172-180. We thank NextCure for their ongoing support of this project (CLR).

Forearm Muscle Strength Assessment by Means REMS Technology *Paola Pisani[1], Fiorella Anna Lombardi[1], Chiara Stomaci[1], Fabiola Rosa Contaldo[2], Maurizio Muratore[3], Tommaso De Marco[4], Luigi Antelmi[4], Sergio Casciaro[1]. [1]Istituto di Fisiologia Clinica, Consiglio Nazionale delle Ricerche, Lecce, Italia, Italy. [2]Università del Salento, Dipartimento di Ingegneria dell'Innovazione, Lecce, Italia, Italy. [3]Vito Fazzi Hospital, ASL-LE, Lecce, Italy, Italy. [4]R&D Department, Echolight S.p.a., Lecce, Italy, Italy

Muscle Diseases, also known as myopathies, are a group of disorders that affect the human muscle system and their main manifestation is skeletal muscle weakness, reduced muscle function, and sometimes muscle wasting. Sarcopenia represents a main contributor to the burden of musculo-skeletal conditions. It is a medical term used to describe the loss of skeletal muscle mass, strength, and function. The literature shows that muscle and bone are physiologically related, and therefore sarcopenia and osteoporosis coexis, in fact, it is estimated that over 30% of fractured individuals are also affected by sarcopenia. Therefore, the aim of this study is to assess the level of forearm muscle strength by means of a Radiofrequency Echographic Multi Spectrometry (REMS)-based algorithm.For the evaluation of the forearm musculature, when the patients was in supine position with the elbow joint fully extended, an ultrasound scans of the dominant forearm by using a 40-mm linear probe (EchoStation device made by Echolight S.p.a., Italy) was performed in the transverse projection considering ulna and radius as reference anatomical sites. In addition, to estimate the MVC (maximum voluntary contraction) of the dominant arm for each subject, a hand dynamometer grip was used and only the maximum obtained value was included in the subsequent analyses.In this study, 30 healthy subjects were enrolled, with a mean age of 40 years and BMI in the range of 18.5-29.1 kg/m2. The automatic REMS-based algorithm used to investigate lumbar and femoral sites, was optimised in order to extend its use for muscle assessment. An automatic identification and analysis of the region of interest (ROI) of the forearm muscles allows to predict MVC value. An accurate data analysis showed a high correlation between the value of MVC and the corresponding value predicted by the algorithm (MVCREMS) with a Pearson's coefficient of 0.94 (p-value < 0.001).The obtained data demonstrate that REMS technology can estimate the muscle strenght of the dominant forearm. Therefore, REMS lets have innovative possibilities for the assessment of both muscle and bone, enabling an overall estimation of musculo-skeletal pathology by improving prevention and diagnosis.

A pilot study of low-intensity vibration training to reduce symptoms and improve gait and stability in cancer survivors with chemotherapy-induced peripheral neuropathy (NCT04170075) *Kerri Winters-Stone[1], Kendra Braun[1], Becky Chan[1], Stephanie Krasnow[1], Sydnee Stoyles[1], Nathan Dieckmann[1], Eric Roeland[1], Clinton Rubin[2]. [1]Oregon Health & Science University, United States. [2]Stony Brook University, United States

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a debilitating and dose-limiting side effect of systemic cancer therapy. CIPN can persist after treatment ends and is associated with functional impairments, abnormal gait patterns, postural instability, and injurious falls. Low-intensity vibration (LIV) may reduce symptoms of CIPN and improve gait and stability, but it has never been tested.Methods: We conducted a pilot randomized controlled trial comparing LIV to usual care (UC) on symptoms and mobility in cancer survivors with persistent CIPN (n=40). Participants completed chemotherapy for early-stage adult-onset cancer within the previous 5 years and self-reported the presence of any CIPN. Participants assigned to LIV were asked to complete 2 x 10-minute LIV sessions daily for 12 weeks using a vibration platform (Marodyne LiV®; dose: 30 Hz, 0.4g). While standing on the LIV platform, participants were encouraged to slowly sway in a clockwise fashion . Outcomes included self-reported CIPN using the FACT/GOG-NTX, assessing the presence and severity of CIPN. Postural sway was measured using an instrumented (iSWAY, Mobility Lab, Clario, Inc) 30-second quiet stance test. Gait was measured using a 7-foot instrumented timed-up-and-go test (iTUG). Given our small sample size for this pilot, we report effect sizes using Cohen's d. Analyses were repeated, limiting the LIV group to those with compliance rates above 50%.Results: Overall, 38 participants provided pre- and post-data for analysis (age: 60.1 + 9.4 years; 22.6 + 17.6 months past chemotherapy completion). One statistical outlier was removed from the outcome analysis (n=20 in LIV and n=17 in UC). On average, LIV participants completed 82% of prescribed sessions with 1 moderate adverse event (foot discomfort). There was a small positive effect size of LIV vs UC for CIPN symptoms (Cohen's d = 0.4), which increased to moderate when removing non-compliant participants (Cohen's d = 0.6). There were moderate to large effect sizes favoring LIV vs UC for TUG time (Cohen's d = 0.6), step number (Cohen's d = 0.6), centroidal sway frequency (Cohen's d = 0.8), and sway velocity (Cohen's d = 0.5). Effect sizes improved slightly when removing non-compliant participants.Conclusions: LIV shows promise for CIPN symptom relief and improving stability and gait in cancer survivors with persistent symptoms. A larger, fully powered controlled trial that includes falls as an outcome is warranted.

Cortical bone remodeling is performed by basic multicellular units (BMUs), which couple resorption and formation to replace discrete packets of bone. This coupling is the foundation of classic histomorphometric evaluation of BMU dynamics. For example, the rate at which formation longitudinally advances may be directly evaluated with sequential fluorochrome labels and has been used to indirectly infer the rate of resorption (i.e., longitudinal erosion rate; LER), assuming synchronized and equal advance of resorption and formation fronts. In the case of glucocorticoid-induced osteoporosis, bone formation is greatly reduced and BMUs have been described as uncoupled, with formation being absent or delayed, such that inferring LER is not feasible. To address this knowledge gap and test the hypothesis that glucocorticoids alter LER we used an in vivo imaging protocol to track individual remodeling events and determine the LER of cortical BMUs in rabbits treated by ovariohysterectomy (OVH), glucocorticoids (GC), a combination thereof (OVH+GC) and SHAM controls (n=5 per group). Ten weeks post OVH or sham surgery, and two weeks after the initiation of dosing (daily subcutaneous injections 1ml of saline or 1.5mg/kg/day of methylprednisolone sodium succinate), the right tibiae were scanned in vivo using in-line phase contrast micro-CT (voxel size=13?m) at the Canadian Light Source synchrotron.

Following two additional weeks of dosing, the rabbits were euthanized and ex vivo images were collected using desktop micro-CT (voxel size=5?m). The datasets were co-registered in 3D and LER was calculated as the distance traversed by BMU cutting-cones in the 14-day interval between scans. The median LERs of OVH and SHAM rabbits were similar at 41.28 and 40.06µm/day [1] (p=0.307), respectively. BMUs in the GC and OVH+GC group were largely arrested, indicated by a median LER of 2.89 and 3.10µm/day, respectively, both of which were significantly slower than LER in OVH and SHAM (p<0.001). Despite the lack of longitudinal advance, radial resorption of the remodeling space was evident in many of the GC and OVH+GC BMUs (Fig. 1). It is known that GCs disrupt BMU coupling, primarily impacting osteoblasts; however, our results provide a novel 4D perspective that suggests, in addition to impaired formation, GC treatment can also lead to the creation of remodeling spaces that fail to progress longitudinally.[1] Previously reported by Harrison et al. JBMR. 2022 Nov; 37(11): 2244-2258.

Glucocorticoids (GC) are inactivated in the kidneys by 11?-hydroxysteroid dehydrogenase type 2 (11?-HSD2) and reactivated at sites of inflammation by 11?-hydroxysteroid dehydrogenase type 1 (11?-HSD1). We investigated the role of 11?-HSD1 in the activation and inactivation of glucocorticoids by analyzing effects in bone in vitro and in vivo.Two different human osteoblast-like cell models were stimulated with prednisone, or prednisolone with or without inhibition of 11?-HSD1 activity. Subsequently, GC metabolites were analyzed in combination with adipogenic and osteogenic differentiation. The in-vivo study included 216 patients treated with prednisolone or methylprednisolone for different inflammatory diseases. Bone mineral density (BMD), fractures, and history of falls were investigated in combination with genotyping for single nucleotide polymorphisms of HSD11B1 as parameter of 11?-HSD1 activity.In our study, the conversion of prednisone to prednisolone and vice versa in human models of mesenchymal stem cells is catalyzed by 11?-HSD1. This mechanism affects cell differentiation. In patients treated with prednisolone for inflammatory diseases, the oxidative capacity of the enzyme is the main factor influencing BMD.Further investigations of patients and the development of pharmaceuticals influencing 11?-HSD1 enzyme function should therefore also focus on its oxidative capacity.

Impact of HIV on tibial bone density, geometry, and strength in midlife Zimbabwean Women and association between pQCT outcomes and fracture *Micheal O'Breasail[1], Cynthia Mukwasi-Kahari[4], Tafadzwa Madanhire[4], Victoria Simms[4], Lisa Micklesfield[3], Rashida Ferrand[4], Celia Gregson[5], Kate Ward[6]. [1]Monash University, Australia. [4]The Health Research Unit (THRU) Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe ; LSHTM, Zimbabwe. [3]SAMRC/Wits Developmental Pathways for Health Research Unit, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, South Africa. [4]The Health Research Unit (THRU) Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe ; LSHTM, United Kingdom. [5]University of Bristol, United Kingdom. [6]MRC Lifecourse Epidemiology Centre, University of Southampton, United Kingdom

Background: HIV and its treatment are associated with deficits in bone and an increased risk of fracture; however, limited data are available from sub-Saharan African women during midlife, and importantly during the menopause transition. We used peripheral QCT to measure tibial bone density, geometry, and strength in pre- peri-, and postmenopausal Zimbabwean women living with (WLWH) and without HIV (WLWOH). and determined whether pQCT measures were associated with self-reported fractures.Methods: Tibia pQCT scans were obtained from 384 women aged 40-61 years (n=191[49%] +Ve). pQCT outcomes were: 4% total area (Tot.A4, mm2), trabecular volumetric bone mineral density (Trab.vBMD, mg/cm3), and compressive bone strength (BSIc, g2/cm4); 38% cortical vBMD (Ct.vBMD, mg/cm3), total area (Tot.A38, mm2), and Stress-Strain Index (SSI, mm3). Height (m) weight (kg) and menopause status based on last menstrual period were recorded (pre=regular period; peri= irregular period/ ammenhorea <= 12 months; post > 12months after last period). Linear regression investigated differences adjusting for age, menopause stage, and height, and then additionally for weight. In all women, odds ratios were calculated to test whether pQCT measures were associated with self-reported 1) any fracture; 2) major osteoporotic fracture.Results: Women were of mean(SD) age 49.6(5.8) years and BMI 29.0(6.1) kg/m2. Weight and BMI were lower in WLWH (both p<0.001), with no differences in age or height. All unadjusted pQCT outcomes except Tot.A4 were lower in WLWH (all p<0.05, Figure 1). These relationships were robust to adjustment for age, menopause stage, and height (all p<0.001) apart from Tot.A38. Further adjustment for weight attenuated only the between-group difference in SSI. BSIc and SSI were associated with lower odds of previous major osteoporotic fracture (OR[95%CI]: BSIc, (0.46 [0.26;0.79]); SSI, 0.53 [0.29;0.93]). Conclusion(s): In perimenopausal Zimbabwean women, HIV impacts both tibial trabecular and cortical bone density. These relationships were robust to adjustment for age, menopause status and height, though the addition of weight to the models reduced the effect size. In the whole group, pQCT outcomes were associated with self-reported MOF. Further investigation will explore in greater detail how body composition and its determinants may explain the observed HIV-related differences and fracture risk.

Table 1. Linear regression to determine the extent of between-group differences between perimenopausal Zimbabwean women aged 40-61 years

N=384	Unadjusted model		Adjusted for age, menopause, and height		Adjusted for age, menopause, height, and weight

ER? signaling in resident synovial macrophages promotes inflammatory arthritis via the activation of cellular metabolism *Yuuki Imai[1], Noritaka Saeki[2]. [1]Ehime University Prote-Science Center, Japan. [2]Ehime university, Japan

Rheumatoid arthritis is an autoimmune disease that exhibits sex differences in prevalence and pathogeneses. It has been suggested that female sex hormones are related to such sex differences, however molecular mechanisms of sex hormones and these receptors remain unclear in rheumatoid arthritis. Especially, the functions of sex hormone receptors in macrophages are largely unknown.We found the levels of ER? mRNA was the highest among examined sex hormone receptors (ER?, ER?, Gpr30, PR, AR) in synovial macrophages derived from serum-transfer arthritis (STA) by RT-qPCR. Thus, myeloid-specific ER? knockout mice (cKO, LysMCre; ER?flox/flox) and littermate control mice (Ctrl, ER?-flox/flox and LysMCre; ER?flox/+) were established and induced experimental arthritis. Development of STA pathogenesis was significantly inhibited in female cKO compared to Ctrl, but not in male. Flow cytometry analysis showed that the proportions of blood-monocyte subpopulations were almost comparable between Ctrl and cKO, and parabiosis with Ctrl and cKO indicates similar STA pathogenesis, suggesting that ER? signaling in resident synovial macrophages promotes inflammatory arthritis. scRNA-seq analysis using synovial cells obtained from STA on day 3 showed increased cell number of resident synovial macrophage clusters (Lyve1+ cluster and Cx3cr1+ cluster) in cKO compared to Ctrl. Gene ontology analysis against highly expressed genes in Ctrl than cKO showed significant enrichment in the biological process termed “metabolic process” in both Lyve1+ and Cx3cr1+ clusters and in the pathway termed “positive regulation of cell death” in Lyve1+ cluster. To understand cellular metabolism dependent on ER? signaling in macrophages, extracellular acidification rate (ECAR) and oxygen consumption rate (OCAR) were analyzed by flux analyzer using bone marrow macrophages derived from Ctrl and cKO. ECAR and OCAR were significantly reduced in cKO-derived macrophages under M1 and M2 conditions, respectively.Collectively, these data suggested that ER? signaling promotes arthritis pathogenesis via the activation of cellular metabolism in resident synovial macrophages.

Itaconate-producing neutrophils regulate local and systemic inflammation following trauma *Robert Tower[2], Janna Crossley[2], Sonya Ostashevskaya-Gohstand[2], Stefano Comazzetto[2], Jessica Hook[2], Lei Guo[2], Neda Vishlaghi[2], Conan Juan[2], Lin Xu[2], Alexander Horswill[3], Gerta Hoxhaj[2], Jessica Moreland[2], Benjamin Levi[4]. [2]University of Texas Southwestern Medical Center, . [2]University of Texas Southwestern Medical Center, United States. [3]University of Colorado, United States. [4]UT Southwestern Medical Center, United States

A fundamental question following injury or infection relates to the ability of the immune response to both initiate and halt the inflammatory process. Due to the evolving role of cellular metabolism in regulating cell fate, function, and inflammation, tendon from control mice or mice subjected to a dorsal burn and full transection of the Achille’s tendon (known to promote the formation of heterotopic ossification [HO]), were evaluated by metabolic profiling to determine its impact on healing outcomes. In addition to bioenergetic changes associated with injury, we observed a significant increase in the immunomodulatory metabolite itaconate following injury (120+/-43-fold increase relative to uninjured tendon, $p<0.001$). In the context of infection and injury, macrophages have previously been shown to produce itaconate to facilitate their conversion from a more pro- to anti-inflammatory state. Single-cell RNA sequencing and subsequent molecular and metabolomic validation identified a highly mature neutrophil subtype, not macrophages, as the primary producers of itaconate following trauma (2.47+/-0.32-fold increase in itaconate in neutrophils relative to macrophages, $p<0.05$). This neutrophil-mediated itaconate production was similarly found in response to TNF? or a simulated bacterial infection in both mouse and human neutrophils, suggesting a conserved response to various forms of inflammation. These mature itaconate-producing neutrophils are highly inflammatory, producing cytokines that promote local HO formation (e.g. Il1b, Tnf) before cycling back to the bone marrow. In the bone marrow, treatment with itaconate was shown to alter hematopoiesis, skewing progenitor cells towards the granulocyte monocyte lineages (132+/-46%, $p<0.01$) and away from the megakaryocyte erythrocyte lineages (-72+/-11%, $p<0.01$), thereby regulating systemic inflammation. Therapeutically, exogenous itaconate was found to reduce injury site inflammation, promoting tenogenic differentiation and impairing aberrant vascularization with disease, ameliorating effects on HO (2.0+/-0.6mm3 vs 3.1+/-1.4 mm3 total HO in control, $p<0.05$). These results demonstrate a therapeutic potential for exogenous itaconate to mitigate HO and present an intriguing role for cycling neutrophils as a sensor of inflammation induced by injury, potentially regulating immune cell production in the bone marrow, through delivery of endogenously produced itaconate.

Inflammation Activates Wnt Canonical Signaling and Induces New Bone Formation Through Toll-Like Receptor 2 *Petra Henning[1], Ali Kassem[2], Anna Westerlund[1], Lei Li[1], Pernilla Lundberg[2], Cecilia Engdahl[1], Vikte Lionikaite[1], Pernilla Wikström[2], Catharina Lindholm[1], Pedro P. C. de Souza[3], Sofia Movérare-Skrtic[1], Ulf H. Lerner[1]. [1]Sahlgrenska Academy at University of Gothenburg, Sweden. [2]University of Umeå, Sweden. [3]Federal University of Goias, Brazil

It is well established that inflammatory processes in the vicinity of bone often induce osteoclast formation and bone resorption. Effects on bone formation by inflammatory processes are, however, much less studied. The present study assessed the effect on bone formation by locally induced inflammation. The Toll-like 2 receptor (TLR 2) agonists Pam2 (synthetic ligand) and LPS from Porphyromonas gingivalis were injected once subcutaneously above skull bones of 5-weeks-old mice. Five days after injection, the calvarial bones were dissected and analyzed by ?CT, static and dynamic histomorphometry, immunohistochemistry (IHC), gene expression, and in situ analyses. Both agonists induced new bone formation primarily at endocranial surfaces. Bone formation at pericranial and intracranial surfaces was also observed. New bone formation could be observed in close vicinity to osteoclasts, but excessive new bone was mainly observed at a distance from osteoclasts and bone resorption cavities. Inflammation increased endocranial bone formation rate due to increased mineralizing surfaces. The injection resulted in progressively increased calvarial thickness during the subsequent 23 days. Treatment with antibodies neutralizing RANKL robustly decreased osteoclast numbers and inflammation-induced bone loss as expected but did not affect the increase of bone formation. Similar observations were made with zoledronic acid. In areas close to new bone formation, there was an abundance of proliferating cells as assessed by Ki67 labeling. TLR 2 activation increased mRNA expression of genes encoding bone matrix proteins (Col1a1, Bglap), Alpl and the osteoblastic transcription factors Runx2 and Sp7, as assessed by qPCR. These observations were confirmed by RNAScope demonstrating the presence of cells expressing Runx2 mRNA. IHC showed robust Runx2 and alkaline phosphatase protein expression in osteoblasts in areas with new bone formation. qPCR analysis showed that TLR 2 activation increased the mRNA expression of Lrp5, Lrp6 and Wnt7b and decreased the expression of Sost and Dkk1. RNAScope demonstrated expression of Wnt7b mRNA in areas with new bone formation. In conclusion, these data suggest that inflammation, not only stimulates osteoclastogenesis, but also locally activates new bone formation through canonical WNT signaling. Importantly, this process is independent of bone resorption and, therefore, should be regarded as inflammation-induced bone modeling.

Temporal osteoclast ablation reduces adaptive immune reactivity in the bone marrow microenvironment *MARGARET DURDAN[1], Anders Narum[3], ANGELO GUILATCO[1], Christine Hachfeld[3], GABRIEL ALVARES BORGES[3], David Monroe[4], Sundeep Khosla[5], Megan Weivoda[3]. [1]Mayo Clinic/University of Michigan, . [3]Mayo Clinic, . [3]Mayo Clinic, United States. [4]Mayo Foundation, United States. [5]Mayo Clinic College of Medicine, United States

Osteoclasts (OCs) are myeloid derived, bone resorbing cells. More recently, OCs have also been reported to have immune functions, including regulation of T cell responses in vitro. However, our understanding of the role for OCs in T cell regulation in vivo is limited. Our in vitro studies revealed that polarization of OCs on bone restricts OC antigen uptake and presentation. Thus, we hypothesize that bone-resorbing OCs in vivo may indirectly impact T cell activation through the release of resorption-derived products. To test this, we evaluated the impact of temporal OC ablation on bone marrow T cells in male and female adult mice. Tamoxifen (TAM)-inducible Cathepsin K CreERT2 mice (CtskCreERT2) were crossed with mice transgenic for conditional Diphtheria Toxin Fragment A (DTA). 4 months old male and female CtskCreERT2-DTA and DTA littermates were treated with 10mg/kg TAM daily for five days (induction) followed by once weekly (maintenance) for

one month (n=5-7). Prior analysis of this regimen revealed the Cre-reporter expression was restricted to OCs on the bone surface; there was no evidence of Cre activity in osteocytes, periosteum, or bone marrow. TRAP staining of vertebral cryosections confirmed significant reduction in OCs in TAM-treated CtskCreERT2-DTA mice compared to DTA littermates. Consistent with this, vertebral BV/TV, Tb.Th, Tb.N were significantly increased, along with a significant decrease in SMI. Flow cytometry analysis of bone marrow immune cells revealed that OC ablation decreased Natural Killer T cells (NKT) populations ($p<0.05$) in male and female CtskCreERT2-DTA mice, along with nearly significant decrease in Th17 cells ($p=0.06$). Single cell RNA sequencing (scRNA seq) of a subset of female mice (n=3) confirmed decreased NKT and NK cells in CtskCreERT2-DTA compared to TAM treated DTA littermates, as well as decreased effector cytotoxic CD8 T cell and increased naïve CD8 T cells; a trend for increased Treg populations in CtskCreERT2-DTA female mice was also noted. There were no significant changes to macrophage, monocyte, or dendritic cell populations, but decreased mature B and plasma cells. Altogether these results show that temporal OC ablation induces an immune tolerance phenotype, suggesting that OC or OC resorption may help to maintain immune reactivity in the bone marrow niche. These findings raise important questions regarding the impact of anti-resorptive therapies on the efficacy of immune therapies in cancer bone disease.

Critical environmental control of B cell lymphopoiesis in the bone marrow through VEGF and PDGF signaling in skeletal stem/progenitor cells *Seppe Melis[1,] Marion Mesnieres[1,] Dana Trompet[1,] Laura Tack[1,] Roger Valle-Tenney[1,] Christa Maes[1,] [1]KU Leuven, Belgium

The bone marrow (BM) microenvironment plays vital roles in hematopoiesis, supporting hematopoietic stem cells (HSCs) and their lineage differentiation. However, the cellular-molecular control of B cell development in the BM remains incompletely understood. Analyzing hypoxia signaling in osteolineage cells, we found that Osx-Cre-mediated conditional knockout (cKO) of von Hippel-Lindau (Vhl), a negative regulator of hypoxia-inducible factor (HIF), led to a marked high bone mass and BM hypervascularization. Here, we investigated the impact on hematopoiesis. Flowcytometry revealed that Vhl cKO mice showed drastically impaired B lymphopoiesis, with >2-fold reduced circulating and BM-resident B cells, from juvenile ages onward. The deficit was due to a specific differentiation block at the transition from pre-pro- to pro-B cells in the BM. To elucidate the mechanism by which activated HIF signaling in bone cells led to a block in B cell development, we next tested the impact of Osx-Cre-driven conditional transgenic (cTg) over-expression of VEGF, the major angiogenic downstream target of HIF. VEGF cTg mice, like Vhl cKO mice, exhibited increased trabecular bone and vascularization, and drastically reduced B cells. The impact was B cell-specific, as the frequency of HSCs, myeloid progenitors and other blood cells was unaltered. Known niche-derived B lymphopoiesis regulators (IL-7, Cxcl12, SCF, Flt3l) were expressed normally. However, data from immunofluorescence, 3D deep-tissue imaging, qPCR and flowcytometry, altogether implicated increased platelet-derived growth factor receptor (PDGFR) signaling in the phenotype. VEGF cTg mice had more metaphyseal (H-type) blood vessels, associated with a dramatic expansion and altered distribution of reticular and perivascular skeletal stem/progenitor cells (SSPCs) marked by PDGFR?, PDGFR? and LepR. Strikingly, the metaphyseal and endosteal bone areas where the expanded PDGFR?+ cells localized, specifically corresponded to the regions of B220+ B cell depletion in VEGF mutants. Finally, evidencing its mechanistic involvement, we found that deletion of PDGFR? in Osx+ cells prevented the SSPC expansion in VEGF cTg mice, normalized bone mass, and rescued B lymphopoiesis.This work thus uncovers a critical environmental control of B lymphopoiesis in the hypoxia-sensitive BM, through VEGF and PDGFR? signaling in SSPCs determining the architecture, cellular composition and functionality of the B cell-supportive stromal-vascular niche.

Addressing the Gap: Does US FRAX Adequately Account for Racial and Genetic Differences in Postmenopausal Women's Fracture Risk? *Qing Wu[1,] Jongyun Jung[2,] [1]The Ohio State University College of Medicine, United States, [2]The Ohio State University, United States

The current US Fracture Risk Assessment Tool (FRAX) presents unresolved concerns regarding the adjustment of racial and ethnic factors, leading to potential healthcare disparities in fracture risk assessment among US postmenopausal women. Our study investigates the influence of race and genetics on fracture prediction performance, aiming to identify opportunities for enhancing the precision of FRAX. Using genomic and phenotypic data from the Women's Health Initiative (WHI) study, we calculated a Genome-Wide Polygenic Risk Score (GPS) employing the LDPred algorithm with 103,155 genetic variants. We categorized GPS into High (top 25%), Medium (25% to 75%), and Low (bottom 25%) groups. We estimated fracture probability with FRAX integrated with bone mineral density (BMD) in the WHI study (N=1522), focusing on major osteoporotic fractures (MOF) and hip fractures as primary outcomes. We derived the observed 10-year fracture probability for MOF using the cumulative incidence function while accounting for competing mortality risk. We computed the FRAX score with BMD for the 10-year probability of MOF and hip fracture. We applied a multivariable Cox proportional hazard model adjusted for baseline FRAX probability to assess the hazard ratio for GPS and race concerning survival time to the first fracture or death. Our findings reveal that FRAX with BMD significantly underestimates MOF risk in minority women, including African American, Hispanic, and other ethnic groups. Multivariate analysis shows that African American and Hispanic women have a 64% and 48% lower hazard than Caucasian women after adjusting the FRAX score. Moreover, the 10-year probability of MOF, adjusted for the FRAX score, is 47% and 62% higher in the median and high GPS groups, respectively, compared to the low GPS groups. These results remain consistent in sensitivity analyses using hip fracture outcomes and additional adjustments for FRAX probability and other factors. We conclude that the current US FRAX with BMD inadequately adjusts for race/ethnic differences. Incorporating accurate racial adjustments and genetic differences could significantly improve FRAX performance in fracture risk assessment.

Table 1. Adjusted Hazard Ratios (HR) and 95% Confidence Intervals (CI) for Fracture Incidence by Race and GPS Group: Multivariate Cox Proportional Hazard Model Analysis in WHI Data with BMD and Genetic Information (N=1,522)

	Major Osteoporotic Fracture	Hip Fracture

Associations of Race, Skin Pigmentation, and Genetic Similarity with Bone Mineral Density in Adolescents *Catherine Gordon[1,] Abby Fleisch[2,] Marie-France Hivert[3,] Lisa Rokoff[2,] Sheryl Rifas-Shiman[3,] Emily Oken[3,] [1]Department of Pediatrics, Baylor College of Medicine, United States, [2]Center for Interdisciplinary Population & Health Research, MaineHealth Institute for Research, United States, [3]Department of Population Medicine, Harvard Medical School, United States

Background: Use of race and ethnicity in clinical decision-making has come under scrutiny, including in the evaluation of bone mineral density (BMD) by dual-energy x-ray absorptiometry (DXA). Rates of osteoporosis and fracture appear to be lower in Black adolescents and adults.Purpose: To evaluate the associations of reported race, skin pigmentation, and genetic similarity with BMD in a cohort of adolescents.Methods: We conducted a cross-sectional analysis of 509 adolescents (mean age 17.5y, range 16-20y) in the Boston-area Project Viva cohort. Exposures were maternal report of adolescent race and ethnicity, self-report of skin pigmentation, and principal components (PC) derived from genome-wide genotyping arrays. The outcome was BMD Z-score (BMDz) standardized for age, sex, and height. We conducted linear regression analyses with the three exposures individually and in combination.Results: Participants were 65% non-Hispanic White (NHW) and 14% non-Hispanic Black (NHB). They identified varying skin pigmentation across 6 categories ranging from "extremely fair" (8%) to "dark brown" (3%), which did not track exactly with reported race. BMDz was higher in those who identified as NHB vs. NHW (?: 0.96, 95% CI: 0.66, 1.26) and those reporting darker skin pigmentation (e.g., 1.22, 95% CI: 0.57, 1.87 for dark brown vs. fair). Darker skin pigmentation remained associated with higher BMDz within strata of NHB and NHW. The first PC derived from genome-wide genotyping arrays (PC1) captures the variance across the most diverse genetic architecture in a population; NHB participants had a higher value of PC1. PC1 strongly predicted BMDz (9.80, 95%CI: 6.50, 13.10), even after including self-reported race (9.37, 95% CI: 1.24, 17.50) or skin pigmentation (10.19, 95% CI: 4.77, 15.61); whereas both race (0.05, 95% CI: -0.82, 0.92 for NHB vs. NHW) and skin pigmentation (0.16, 95% CI: -0.78, 1.10 for dark brown vs. fair) no longer predicted BMDz after adjustment for genetic similarity.Conclusions: Although genetic similarity reflected in the first PC of genome-wide genotyping arrays strongly predicted BMD, this information is not generally available in clinical settings. Further, whether the relationship between BMD and fracture risk differs by race, skin pigmentation, or genetic similarity, independent of other risk factors, is uncertain. We recommend re-evaluation of adolescent BMD reference data to exclude consideration of race.

Multiscale Analysis Identifies Cell Types and Genes Associated with Bone Mineral Density *Ryan C Chai[1], Mischa Lundberg[2], Monika Frysz[3], J H Duncan Bassett[4], Graham R Williams[4], Peter I Croucher[1], John P Kemp[5]. [1]Bone Biology, Garvan Institute of Medical Research, Australia. [2]The University of Queensland Diamantina Institute, The University of Queensland, Australia. [4]Molecular Endocrinology Laboratory, Department of Medicine, Imperial College London, United Kingdom. [5]Mater Research Institute-University of Queensland, Translational Research Institute, Australia

Background: Bone mineral density (BMD) is a major determinant of bone strength and fracture risk. Genome-wide association studies (GWAS) have identified many variants associated with BMD; however, the underlying cell types and genes remain unclear. Identifying the cellular mechanisms of these genetic determinants is crucial for understanding the pathogenesis of skeletal diseases and developing new therapeutics. We hypothesised that a multiscale approach of integrating GWAS, single cell RNA sequencing (scRNA-seq) data and knockout mouse models would identify cell types and genes associated with BMD. Methods: scRNA-seq was used to define the transcriptome of cells isolated from mouse femurs. Hypergeometric tests were used to identify cell types enriched for genes involved in monogenetic skeletal disorders. MAGMA gene-set analysis was used in conjunction with GWAS of 448,010 participants in the UK-Biobank Study to identify cell types that are enriched for BMD-associated genes. Disease- and BMD-associated genes were validated using skeletal phenotyping data from the mouse genome informatic (MGI) database and in-depth functional analysis of the skeleton in 1000 unselected single gene deletions in mice. Results: scRNA-seq analysis of 133,942 cells identified 34 cell types, including multiple clusters of myeloid, lymphoid, osteoblastic, chondrocytic and vascular cells, each with distinct transcriptional profiles. Osteoblasts and osteoclasts were enriched for genes that cause monogenetic low and high bone mass skeletal disorders respectively. Osteoblasts, chondrocytes, endothelial cells and vascular smooth muscle cells were enriched for BMD-associated genes. Cell type-specific BMD-associated genes were more likely to result in abnormal BMD when deleted in mice. In-depth skeletal phenotyping validated the critical functions of 15 BMD-associated genes, including the novel endothelial cell-specific gene SLC9A3R2, which when deleted in mice resulted in reduced trabecular bone mass.Conclusions: Our multiscale approach identifies cell types, including bone resident cells and vascular cells, in which genetic determinants of BMD may function to influence pathogenesis of monogenetic and polygenetic skeletal disorders with abnormal BMD. This provides a resource to prioritise genes to accelerate development of patient-centred therapeutics for skeletal diseases.

Femoral Neck Width Genetic Risk Score Is A Novel Independent Risk Factor For Hip Fractures *Jonathan H Tobias[1], Maria Nethander[2], Benjamin F Faber[1], Sophie Heppenstall[1], Raja Ebsim[3], Timothy Cootes[3], Claudia Lidner[3], Fiona R Saunders[4], Jenny S Gregory[4], Richard M Aspden[4], Nick C Harvey[5], John Kemp[6], Monika Frysz[7], Claes Ohlsson[8]. [8]Center for Bone and Arthritis Research at the Sahlgrenska Academy, Sweden

Purpose: We investigated whether femoral neck width (FNW) is related to hip fracture independently of femoral neck bone mineral density (FN-BMD) using a genetic approach. Methods: FNW was derived from points automatically placed along the outline of the proximal femur in left hip DXA scans from 38,150 individuals (mean age 63.8 years, 48.0% males) in UK Biobank (UKB). Subsequent GWAS identified 71 independent genome-wide significant FNW SNPs. FNW and FN-BMD SNPs were used to generate genetic risk scores (GRSs), which were examined in relation to incident hip fracture in UKB (excluding the FNW GWAS population; n=338742, 3222 cases) using a Cox proportional hazards model, with sex and baseline age as covariates. Participants were subsequently classified according to binarized FNW and FN-BMD GRS scores, using a 10% cut-off for high/low risk. Results: MAGMA analyses identified different gene sets between FNW GWAS (cartilage differentiation, hedgehog, skeletal development) and FN-BMD GWAS (runx1/Wnt signalling), demonstrating distinct underlying biology of these traits. In multivariable Mendelian Randomisation (MVMR), greater genetically determined FNW increased risk of all hip fractures (OR 1.53; 95% CI 1.29-1.82 per SD increase in FNW) and femoral neck fractures (OR 1.58;1.30-1.92), but not trochanteric or forearm fractures. Greater genetically determined FN-BMD decreased fracture risk at all four sites. FN-BMD GRS was associated with reduced risk of incident hip fractures (HR 0.83;0.80-0.86), and FNW GRS with increased risk of hip fractures (HR 1.08;1.05-1.12) and femoral neck fractures (HR 1.10;1.06-1.15). Individuals with genetically determined low FN-BMD had a more pronounced increased risk from genetically determined high FNW (p=0.04 for FN-BMD GRS x FNW GRS interaction for hip fracture prediction). Using the 10% cut-off for high/low risk, subjects in the high-risk GRS group for both FNW GRS and FN-BMD GRS had a more than two-fold increased risk of hip fractures compared with those in the low-risk group for both binarized GRSs.Conclusions: The underlying biology regulating FNW and FN-BMD differs. DXA-derived FNW is causally related to hip fractures independently of FN-BMD and adds information beyond FN-BMD for hip fracture prediction. FNW derived from DXA analyses or a FNW GRS may contribute clinically useful information beyond FN-BMD for hip fracture prediction.

[6]Center for Bone and Arthritis Research at the Sahlgrenska Academy, Sweden

The gut microbiota (GM) can regulate bone mass in mice and humans, but there is no study on the association between GM composition and incident fractures. A previous human study determining the association between GM composition and bone mineral density indicated that large sample sizes (n>6000) are required to account for the multiple testing when evaluating the high number of taxa present at genus/species levels.The present study mainly aimed to determine whether the overall GM composition - reflected by the alpha diversity (Shannon diversity), beta diversity, and relative abundances of the 10 most abundant phyla (average relative abundance >= 0.0094%) - is associated with incident fractures in the large FINRISK cohort (n=7043, 1092 incident fracture cases, median follow-up time 18 years) with GM composition quantified using shallow shotgun metagenome sequencing. Associations were tested using Cox regression models adjusted for age, sex, prevalent fractures, medications, and recent antibiotic use.We observed that higher alpha diversity was associated with decreased fracture risk (hazard ratio [HR] 0.92 per standard deviation increase in Shannon diversity, 95% confidence interval 0.87-0.96, P=0.006). For beta diversity, the first principal component was associated with decreased fracture risk (Aitchison distance, HR 0.90, 0.85-0.96, P=0.0007). We next determined the associations between the 10 most abundant phyla and fracture risk. Following Bonferroni correction ($p<0.05/10=5.0\times10-3$ required), Proteobacteria was associated with increased fracture risk (HR 1.14; 1.07-1.20, $P=1.0\times10-5$), while Tenericutes was associated with decreased fracture risk (HR 0.90; 0.85-0.96, $P=5.4\times10-4$). The strengths of these associations were mainly unchanged after further adjustments for diet.Explorative sex-stratified analyses showed that Shannon alpha diversity associated with fractures in women (HR 0.88; 0.82-0.95) but not in men (HR 0.99; 0.90-1.08). Further explorative analyses demonstrated that Proteobacteria was associated with increased (HR 1.13, 1.04-1.23) and Tenericutes with decreased (HR 0.90, 0.82-0.99) risk of major osteoporotic fractures (hip, humerus, forearm, and vertebral fractures, n=458) with similar effect sizes as observed for fractures at any bone site.In conclusion, the overall GM composition is associated with incident fractures in the large FINRISK cohort. Further studies are warranted to determine the underlying mechanism.

A novel periosteal cell type, identified by single cell RNA sequencing, senses mechanical loading and in response to it differentiates into osteoblasts *XUEHUA LI[1], Intawat Nookaew[2], Jinhu Xiong[3, 1], United States. [2]University of Arkansas for Medical Sciences, United States. [3]Univ of Arkansas for Medical Sciences, United States

Mechanical loading stimulates periosteal bone formation and osteocytes are considered to be the major cells sensing and transducing mechanical signals in bone. However, a complete understanding of the identity of mechanosensitive cells in periosteum is lacking. To determine which cell types are responding to mechanical stimulation in periosteum, we isolated periosteal cells from loaded tibia at different time points and performed 10X-based single cell RNA sequencing (scRNA-seq). The left tibiae of 7-month-old female C57BL/6J mice were loaded with 9N at 1 bout per day for 1, 2, and 5 days. Periosteal cells were then isolated 12 hours after loading for 12-hour time point and 24 hours after the last set of loading for the 2- and 5-day time points. scRNA-seq identified 8 clusters: Fibro-1, Fibro-2, Osteo-X, Osteoblasts, Chondrocytes, Articular Chondrocytes, Tenocytes, and a new cluster we refer to as Fibro-L. Comparing clusters between the control and 12-hour groups, we found that the number of Fibro-L is greatly increased within 12 hours after loading. The dramatic change of the cell number in this cluster within 12 hours cannot be explained by cell proliferation but the change in gene expression profile induced by mechanical loading. Differential gene expression analysis of this cluster showed increased expression of Ptgs2,

Lif, and Il-6 which are classic early response genes to mechanical loading. To confirm the increased expression of these genes in periosteum, we localized their mRNA using RNAscope based in-situ hybridization. Tibiae collected 4 hours after loading were used for RNAscope. Consistent with scRNA-seq analysis, we found increased Ptgs2, Lif, and Il-6 expression in osteocytes as well as cells at the periosteal surface, suggesting that periosteal cells are also capable of sensing mechanical stimulation. Differential gene expression analysis of this cluster at later time points showed that proliferation related genes such as Ki67 and Top2a were significantly elevated. In addition, RNAscope showed a dramatic increase of Top2a expression in the tibial periosteum 5 days after loading, demonstrating increased cell proliferation in periosteal cells. More importantly, cells in the Fibro-L cluster became Sp7 and Spp1 positive at day 5 consistent with their differentiation towards osteoblasts. Taken together, our results provide evidence that a subset of periosteal cells may directly sense mechanical loads and differentiate into osteoblasts.

RESPONSE OF BONE TO MECHANICAL LOADING IS HERITABLE AND CORRELATES WITH OSTEOCYTE LACUNAR MORPHOLOGY IN MICE *Nicole Migotsky[2], John Shuster[2], Surabhi Kumar[2], Charles Farber[3], Matthew Silva[4]. [2]Washington University in St Louis, . [2]Washington University in St Louis, United States. [3]University of Virginia, United States. [4]Washington University in St. Louis School of Medicine, United States

Mechanical loading is a potent anabolic and anti-catabolic stimulus for bone. Many bone traits are heritable, but little is known about the influence of genetics on the response of bone to increased mechanical loading. In this study we utilized two murine models of genetic diversity, the diversity outbred (DO) population and the eight inbred founder strains (Founders) that were crossbred to create the DO. We hypothesized that loading-induced bone formation varies with mouse genetic background and sex, is moderately heritable, and correlates with osteocyte lacunar morphology. The right tibia of 220 skeletally mature (5 mo-old) mice, including females and males, were loaded in axial compression to a peak tensile strain of 1500 µ?. The diaphyseal cortical responses to loading were assessed using classic dynamic histomorphometry and time-lapse µCT (comparing pre- and post-loading scans). Because osteocytes are thought to regulate the mechanoresponsiveness of bone, loading responses were correlated to lacunar morphology determined in a separate cohort of mice. Loading increased bone formation in a strain/sex dependent manner, with the inbred strain 129S1 having the largest response to loading on both periosteal and endocortical surfaces (ANOVA). Inbred strain A/J did not have a measurable response on either bone surface. Additionally, loading reduced bone resorption in a strain/sex dependent manner. For every measurement of periosteal bone formation, the outbred population (DO) had a higher increase due to loading than the inbred population (Founders). While sex differences were found in some inbred strains, there was no main sex effect when looking at all inbred or all outbred mice as a population. Broad-sense heritability (H2) was calculated for each bone formation outcome in the Founders. All periosteal formation outcomes have heritability over ~80%. Lacunar volume fraction positively correlated with increased loading response, while lacunar aspect ratio negatively correlated with increased loading response. Overall, bone responses to mechanical loading vary with genetic background and are moderately to highly heritable. Additionally, the volume fraction and elongation of osteocyte lacunae are significantly correlated with loading response indicating a relationship between osteocyte morphology and mechanosensitivity. This work supports further use of these genetically diverse mouse models to investigate how genetics regulates bone mechanoresponsiveness.

Regulation of Intracellular cAMP Levels in Osteocytes by Mechano-sensitive Focal Adhesion Kinase *Garyfallia Papaioannou[1], Tadatoshi Sato[2], Parthena Kotsalidis[1], Katelyn Strauss[1], Thomas Dean[1], Matthew Stokes[3], Thomas Gardella[1], Marc Wein[1]. [1]Massachusetts General Hospital, Harvard Medical School, United States. [2]Massachusetts General Hospital, Harvard Medical School and UMass Medical School , United States. [3]Cell Signaling Technology, United States

Introduction Osteocytes are the primary mechano-sensors in bone. Mechanical loading is sensed across their dendritic projections leading to transient reductions in tyrosine kinase focal adhesion kinase (FAK) activity. Previous studies suggested that FAK controls sclerostin expression in osteocytes, and pharmacologic FAK inhibition increases bone formation. However, our understanding of the signaling pathways downstream of FAK in osteocytes is incomplete. This study aims to identify novel bone anabolic pathways controlled by FAK. Methods/Results We performed tyrosine-focused phospho-proteomic profiling via tandem mass spectrometry in osteocyte-like Ocy454 cells to identify FAK substrates. We analyzed the tyrosine phospho-proteome of cells lacking FAK (via CRISPR ??) or treated with pharmacologic FAK inhibitors vs controls. Surprisingly, Gs?, PTH1R, and phosphodiesterase 8A (PDE8A), all proteins associated with cAMP signaling, were found as potential FAK targets based on their reduced tyrosine phosphorylation in both FAK KO or FAK inhibitor treated cells. A Glosensor system was used to measure cAMP levels in HEK293 cells. FAK pharmacologic inhibition or gene deletion increased basal and ligand-stimulated (ligands: isoproterenol, PGE2, PTH) cAMP levels. In Ocy454 cells, both phosphorylated protein kinase A substrate levels and cAMP target genes (Rankl, Wnt4) were increased by FAK inhibitors +/- PTH treatment. Mutating FAK phospho-acceptor sites in Gs? and PTH1R had no effect on PTH or FAK inhibitor stimulated cAMP levels. In addition, FAK inhibitor augmented cAMP levels even in the presence of forskolin that activates adenyl-cyclase downstream of Gs?. Therefore, PDE8A is a possible target and PDE8A inhibition (via PF04957325) in Ocy454 cells led to molecular changes (increased cAMP, PKA activity, cAMP target genes) similar to FAK inhibition. In vitro kinase assay showed that PDE8A is directly phosphorylated by FAK. Initial experiments measuring PKA activity in bones of mice after acute treatment with the FAK inhibitor VS6063 (60mg/kg) and/or PTH (5nmol/Kg) suggest that the effect of FAK inhibition on cAMP signaling also operates in vivo. Conclusion FAK inhibition acts synergistically with signals that activate adenyl-cyclase to increase intracellular cAMP. Mechanically-regulated FAK can modulate intracellular cAMP levels via effects on PDE8A. These data suggest a novel mechanism of crosstalk between mechanical and cAMP-linked hormonal signaling in osteocytes.

Piezo1 Regulates cGMP/PKG Signaling in Osteocyte Mechanotransduction *Yizhong Hu[1], Xinchen Wu[1], Fuhua Wang[1], Yingzi Yang[2]. [1]Harvard School of Dental Medicine, United States. [2]Harvard University, United States

Mechanical stimuli and osteocyte mechanotransduction are critical for maintenance of healthy adult bone. Following mechanical stimulation, increased [Ca2+]in initiates downstream signaling activities modulating bone anabolic responses. Enhanced cGMP/PKG signaling resulting from increased [Ca2+]in promotes osteoblast and osteocyte differentiation.

Recent works from our lab and others have demonstrated that the force-gated calcium ion channel Piezo1 at the cell membrane is required for load-induced bone adaptation. RNA-seq analysis of Piezo1-deficient mouse bones further demonstrated reduced cGMP/PKG signaling. We therefore hypothesize that Piezo1 regulates early mechanotransduction events through the cGMP/PKG pathway.To test this hypothesis, we generated a Piezo1-/- OCY454 osteocyte cell line using CRISPR-Cas9 (Fig. 1A). After 21-day differentiation, Piezo1-/- OCY454 expressed lower levels of osteocyte genes (DMP1, SOST, PHEX, TNFSF11) but higher levels of osteoblast genes (SP7, RUNX2, BGLAP) than WT OCY454, suggesting that Piezo1 deficiency impedes osteocyte differentiation. Furthermore, bulk RNA seq analysis of the differentiated Piezo1-/- and WT OCY454 revealed downregulation of hippo signaling and upregulation of Wnt signaling.In WT OCY454, stimulation by fluid shear stress and Yoda1 treatment, a Piezo1 activator, induced PKG activation measured by increased VASP Ser239 phosphorylation. These effects were abolished in Piezo1-/- OCY454, suggesting that mechanically stimulated Ca2+-dependent PKG activation acts through Piezo1(Fig. 1B). Furthermore, mRNA and protein levels of PKG1 and PKG2 decreased significantly in Piezo1-/- OCY454. Pharmacological activation of YAP, a downstream effector of Piezo1, increased prkg1/2 mRNA and PKG1/2 protein levels, suggesting that Piezo1 may transcriptionally modulate PKG signaling via YAP. Using primary BMSCs isolated from Piezo1f/f mouse, deletion of Piezo1 by Ad-Cre infection reduced osteogenic differentiation measured by ALP staining, consistent with published studies (Fig. 1C). Importantly, PKG activation by 8-pCPT-cGMP treatment rescued osteogenic differentiation defects in Ad-Cre-infected Piezo1f/f BMSCs measured by the number of ALP-positive CFUs. Taken together, these results indicate that Piezo1 regulates cGMP/PKG signaling in osteogenic differentiation and mechanotransduction.

Effects combining mechanical loading with sclerostin antibody, parathyroid hormone, or bisphosphonate treatment on mechanoregulation in trabecular bone in mice *Julia K. Griesbach[1], Friederike A. Schulte[1], Claudia Weigt[1], Marcella von Saglis-Soglio[1], Floor M. Lambers[1], Peter J. Richards[2], Michaela Kneissel[2], Gisela Kuhn[1], Ralph Mueller[3]. [1]ETH Zürich, Switzerland, [2]Musculoskeletal Disease Area, Novartis Institutes for Biomedical Research, Switzerland, [3]ETH Zurich, Switzerland

Osteoporosis is a prevalent disease leading to low bone mass and increased bone fragility often treated with medications such as parathyroid hormone (PTH), sclerostin antibodies (SclAB), or bisphosphonates (BIS). Further, mechanical loading can cause an anabolic bone response. We investigated how the combination of mechanical loading and three pharmacological treatments affects bone mechanoregulation.In vivo micro-computed tomography scans were obtained from the 6th caudal vertebra of ovariectomized (OVX) C57BL/6JRcc mice, treated with mechanical loading only at 0N and 8N (n=27/27) and/or with PTH (n=9/9), SclAB (n=10/10) or BIS (n=9/10), respectively. Formation, quiescent and resorption volumes were identified by registering the scans of week 20 and 22. Strain energy density (SED) was estimated using micro-finite element analysis at week 20. Conditional probabilities associating volumetric remodeling events with SED levels were calculated and parametrized. Area under the curve (AUC) for the receiver operating characteristic and the correct classification rate (CCR) of remodeling probabilities were compared to OVX 0N using unpaired Student's t-test with Bonferroni correction.Concurrent loading improved trabecular bone volume fraction (OVX: 0.0% to 14.5%; PTH: 37.5% to 66.3%, SclAB: 21.1% to 50.2%; BIS: 14.6% to 27.0%; p<0.05). All groups exhibited mechanoregulation, where bone was more likely to be formed in areas with high SED and resorbed in areas with low SED (Fig. 1A,B). While SclAB increased mechanoregulation in formation with and without loading, PTH only had this effect when combined with loading (Fig. 1C). Mechanoregulation of resorption was not significantly affected by PTH or SclAB (Fig. 1 D). BIS decreased mechanoregulation of resorption and formation compared to OVX 0N (Fig. 1C,D). Overall, mechanoregulation of the remodeling process increased when combining PTH or SclAB with mechanical loading and decreased when using BIS without loading (Fig. 1E).Combining mechanical loading and pharmacological treatments affects the mechanoregulatory response in bone. The combination of PTH or SclAB with mechanical loading will target the remodeling response more to the mechanical demands, while BIS treatment will cause a more untargeted response. These insights shed new light on the mechanisms of combined mechano-pharmacological treatments and might help clinicians make more informed treatment plans including physical therapy as an additional option.

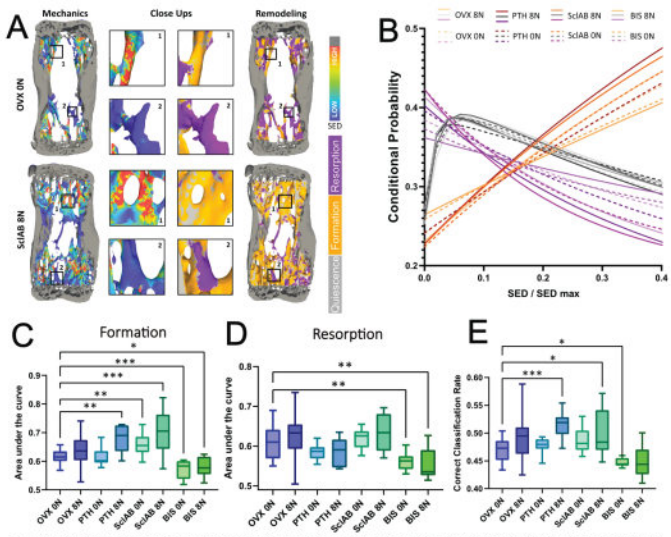

Fig. 1: A) Qualitative comparison mechanical environment and bone remodelling for OVX 0N and SclAB 8N; B) Conditional probabilities for formation (orange), quiescent (grey) and resorption (purple); Area under the curve of the receiver operating characteristic for C) formation and D) resorption; E) correct classification rate *: p<0.05; **:p<0.01; ***:p<0.001

Allelic Effects at the Cped1 Locus Interact with Parathyroid Hormone to Impact Bone Strength in Mice *Yingping Wang[1], Dana Godfrey[1], Robert Maynard[2], Nicole Szeto[1], Veronica Butler[1], Michael David[1], Gregory Ottenberg[1], Douglas Adams[1], Cheryl Ackert-Bicknell[1]. [1]University of Colorado, United States, [2]University of North Carolina, United States

Teriparatide is a recombinant peptide consisting of the first 34 amino acids of Parathyroid Hormone (PTH) and is an anabolic drug for treating osteoporosis. Available data suggests that not all patients respond to Teriparatide, and that response may be genetic. We conducted a Genome-wide Gene-Environment Association study (GWEAS) using Diversity Outbred (DO) mice, with intermittent PTH as the environmental variable. We treated 1173 mice with either PTH (40 ?g/kg/day) or saline for 4 weeks, starting at 12 weeks of age (equal male:female and PTH:saline). Mice were genotyped using the GigaMUGA array. Femur strength was measured in 3-point flexure. Genetic loci were mapped by fitting mixed-effects linear models at each marker and regressing the phenotype on the haplotype probabilities. In model 1, PTH treatment was an additive covariate and in model 2 PTH treatment was an interactive covariate with genotype. In model 1 we identified a quantitative trait locus (QTL) with a peak LOD at 22.31 Mbp (LOD = 8.23, CI = 21.38 to 22.35 Mbp), but in Model 2 the LOD dropped to 4.71, suggesting that this locus interacted with PTH to impact strength. This locus encompassed 6 genes: Kcnd2, Tspan12, Ing3, Cped1, Wnt16 and Fam3c, and is concordant with the human CPED1/WNT16 locus for BMD and fracture. We looked for cis-expression QTL (eQTL) to see if local genetic effects impacted femoral gene expression at this locus, as mapped in a discrete set of PTH naïve 188 female DO mice. No cis eQTL were found for Kcnd2 or Wnt16. For Ing3 and Fam3c, cis eQTL were found but the allele effects did not match those of our strength QTL, eliminating these 4 genes. A strong cis eQTL was found for Tspan12 (LOD 11.90) and the allele effects partially match our strength QTL. No primary eQTL was found for Cped1, but we have shown previously that Cped1 is highly alternatively spliced. When conditioning on the long transcript for Cped1 in a mediation analysis, we found an eQTL for Gm26719 (LOD = 20.79), which is likely a mis-annotated transcript for Cped1. Using mice homozygous for a CRISPR-induced mutation of Cped1, we measured a significant reduction in femoral strength for male Cped1mut femurs (16.7 +/- 1.7 N) relative to Cped1+/+ (18.2 +/- 2.5 N). Future studies will determine how these mice respond to PTH. We cannot rule out Tspan12 as contributory to the primary QTL, but the available data strongly support Cped1 as causative, and that this genetic locus interacts with PTH to impact bone strength.

ROI-based Spatial Transcriptomics as a Novel Approach to Reveal the Mechanism of Quiescent Bone Lining Cells Reactivation *Ahyoun Choi[1], Ji Yeon Lee[2], Sung Hye Kong[2], Chan Soo Shin[2], Sunghoon Kwon[3], Sang Wan Kim[2]. [1]Interdisciplinary Program in Bioengineering, Seoul National University, Republic of Korea. [2]Department of Internal Medicine, Seoul National University College of Medicine, Republic of Korea. [3]Department of Electrical and Computer Engineering, Seoul National University, Republic of Korea

Anabolic agents such as parathyroid hormone (PTH) and anti-sclerostin antibody (Scl-Ab) are highly effective in treating severe osteoporosis by increasing bone mass and restoring bone microstructures. One of the mechanisms by which these agents work is the modeling-based bone formation by reactivating quiescent bone lining cells (BLCs). Given that BLCs make up 80% of the trabecular bone surface, reactivating these cells has emerged as a promising target for osteoporosis treatment due to their potential contribution to bone formation. However, the underlying mechanisms are not fully understood.To investigate the molecular mechanisms underlying the reactivation of BLCs, we utilized a Dmp1-CreERT2:mTmG or Osteocalcin-CreERT2:mTmG mouse model to create four groups: active osteoblasts (Obs), inactive Obs (presumably BLCs), and reactivated Obs with PTH or Scl-Ab. This lineage tracing mouse model rendered target Obs to express green fluorescent proteins (GFP), which allowed us to specifically isolate region-of-interests (ROIs) containing them from mouse calvaria sections using our in-house spatially resolved laser activated cell sorter (SLACS). We performed ROI-based spatial transcriptomics on each group, generating transcriptome data from 100 ROIs in 48 male mice, with 6 mice in each group.Our analysis revealed the reactivated Obs exhibited features consistent with the response of anabolic agents, including increased expression of Col1a1 and Bglap genes and upregulation of canonical Wnt signaling. Notably, the Scl-Ab-treated group showed similar expression patterns to the active group in the Dmp1-CreERT2 mouse model, while the PTH-treated group had the distinct expression profile. Furthermore, differential gene expression analysis revealed upregulation of Kras gene in both the active and Scl-Ab-treated groups, compared to the inactive group. Gene set enrichment analysis showed downregulation of transforming growth factor-beta (TGF-?) signaling in the Scl-Ab-treated group, along with differential expression of Dcn, Apc, and Mmp13 genes. Our findings suggest that Kras and TGF-? signaling could be involved in the interconversion between mature osteoblasts and BLCs.In summary, spatial transcriptomics combined with lineage tracing mouse models sheds light on the genetic characteristics of BLCs and reactivated osteoblasts. Further functional studies are required to elucidate the possible role of Kras or TGF-? signaling in BLC reactivation.

Although bisphosphonates (BPs) are well established for treating bone disorders, many clinical and other studies suggest BPs also have beneficial extra-skeletal effects on cardiovascular disease, respiratory infections, some cancers, neurodegeneration and mortality. However, the mechanisms by which BPs induce such effects are unclear. Using multi-cell screening and studies of BP-treated aged mice and human patients, combined with genomic, transcriptomic, and proteomic analysis, we explored the hypothesis that BPs exert direct effects outside the skeleton to impact multiple aspects of aging.In multiple cell types, established and novel BPs (incl ZOL, ALN, OX14) increased cell growth at low doses (live cell imaging analysis, 1nM-0.1uM, up to 36%, p<0.01). Using fluoro-tagged BPs (ROX-RIS, FAM-ZOL, 0.1uM) to study whether BPs gain access to non-skeletal cells, we showed internalization and co-localization with lysosomal and endosomal organelles (kidney, liver, epithelia, cardiovascular, lung, prostate cells) in vitro. In vivo spatial transcriptomic analysis revealed differentially expressed genes/pathways in multiple organs of aged (24mth) ZOL-treated (125ug/kg) animals vs. untreated, including senescence markers SESN3, CLEC2J and ASB9 (p<0.05) with a shift in cellular composition toward those of young (12wk) untreated mice. Similarly, a 5000-plex plasma proteome analysis from osteopenic patients before/after ZOL treatment (36mth) showed significant alterations in ~400 proteins including GTPase regulators, and markers of senescence, autophagy and inflammatory responses. Following this, a mass spectrometry-based cellular thermal shift assay confirmed multiple ZOL-protein interactions (TP-MAP analysis). Reassuringly FPPS was the most BP-bound protein, but we found many similarly stabilized proteins previously unassociated with BP action such as PHB2, FOSL1, CLTB (p80 genes including those linked to cell cycle regulation, and senescence (e.g. CCDC68, CDC14B, IGFBP5, PRKACB, p<0.001). Functional cellular analyses confirmed pre-treatment of cells with BPs protected against the onset of DNA damage-induced senescence (SA-?-gal, ?-H2AX, x2 fold, p<0.01). These multi-omic analyses reveal both novel BP-binding proteins and unidentified transcriptomic/proteomic alterations in non-skeletal cells via which BPs might protect against human aging-linked disorders.

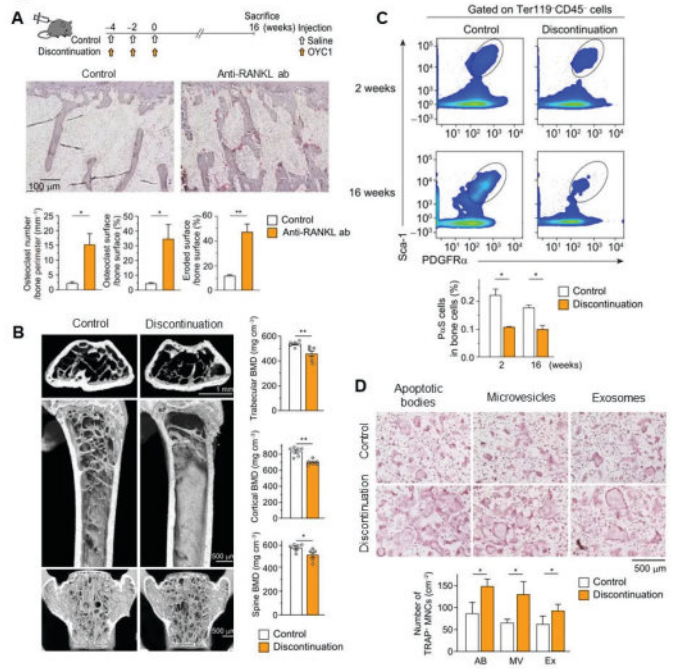
[8]Department of Medicine for Orthopaedics and Motor Organ, Juntendo University , Japan

The discontinuation of denosumab (anti-RANKL antibody) therapy may lead to an increased risk of multiple vertebral fractures in various pathological conditions. However, the pathophysiology underlying this risk is largely unknown.Eight patients who underwent discontinuation after multiple injections of denosumab had higher levels of TRAP-5b, the so-called “overshoot” phenomenon, compared to their pre-treatment levels. The rate of decrease in bone mineral density (BMD) during the withdrawal period was higher than in age-matched non-treated patients, suggesting a decrease in BMD independent of age-related physiological bone metabolism.To know the pathology of bone loss after discontinuation, we analyzed mice injected with anti-RANKL antibody. Overshoot and significant bone loss were observed in mice receiving continuous anti-RANKL antibody administration after treatment cessation, resembling the original pathology (Figure A and B). Bone mass rapidly decreased during overshoot (in vivo CT), and the ratio of mineral contents in the bone matrix was also reduced (FTIR). This deterioration of bone structure and quality resulted in bone fragility (three-point bending test). Furthermore, in mice long out of overshoot, bone resorption recovered, but osteoblast numbers and bone formation remained markedly reduced, even at the late phase (16 weeks after discontinuation). In the bone marrow, the number of Sca-1- and PDGFR?-expressing osteoblast progenitors (P?S cells) and ALP-positive early osteoblasts was greatly reduced (Figure C). These results suggested that sustained inhibition of osteoblastic lineage cells resulted in long-lasting bone loss.To explore the mechanism of overshoot of bone resorption, osteoclastic lineage cells were examined. Just before the overshoot, bone marrow cells contained a higher number of osteoclast precursor cells (c-Fms +cells), which formed TRAP+ mature osteoclasts more effectively than the control. RANKL levels were also elevated in mice injected with anti-RANKL antibody during overshoot. We found that these mice had higher amounts of RANKL-enriched extracellular vesicles (EVs) in sera, and that purified EVs stimulated osteoclastogenesis (Figure D). Thus, the accelerated bone resorption due to the accumulation of RANKL-bearing EVs and the long-term suppression of bone formation uncoupled from bone resorption leads to the severe bone loss that is characteristic of denosumab treatment discontinuation.

Figure



A. Schematic of the experimental setting for the mouse model of anti-RANKL discontinuation (Upper). Bone histomorphometric analysis in the proximal tibia of control (n = 3) and discontinuation mice (n = 3) 8 weeks after the last injection (Middle: TRAP staining).
B. Representative μCT images of the distal femur and spine of control (n = 8) and discontinuation mice (n = 8) 16 weeks after the last injection (Upper, axial view of metaphyseal region; middle, longitudinal view of femurs; lower, coronal view of spine).
C. The percentage of osteoblastic progenitors characterized by surface expression of PDGFRα and Sca-1 positive cells (PαS cells) in the femur of control (n = 4) and discontinuation mice (n = 4).
D. Effect of extracellular vesicles isolated from control and discontinuation mice serum during the overshoot period on the osteoclastogenesis of normal bone marrow monocyte/macrophage lineage cells. Representative images and the number of TRAP⁺ multi nucleated cells are shown (n = 4/groups).

Osteocyte RANKL is Critical for the Development of Cortical Porosity and High Bone Turnover in an Animal Model of Chronic Kidney Disease

*Corinne Metzger[3], Mizuho Kittaka[2], Alec Laplant[3], Yasuyoshi Ueki[2], Matthew Allen[3]. [3]Indiana University School of Medicine, . [2]Indiana University School of Dentistry, United States. [3]Indiana University School of Medicine, United States

Skeletal fragility and high fracture rates are common in chronic kidney disease (CKD). They contribute to reduced quality of life and increased mortality. A key component of bone loss in CKD with secondary hyperparathyroidism is cortical bone deterioration through both cortical thinning and the development of cortical porosity. Cortical porosity development progresses rapidly in both human CKD patients and animal models demonstrating it is a phenotype not directly tied to basal levels of intracortical remodeling (which is lacking in most rodents). We hypothesize that receptor activator of nuclear factor-?B ligand (RANKL), specifically from osteocytes, drives high bone resorption within cortical bone leading to the development of cortical porosity. To explore this hypothesis, we utilized male and female Dmp1-cre RANKL fl/fl mice after 10 weeks of adenine-induced CKD (Ad-CKD; 0.2% dietary adenine). All Ad-CKD mice regardless of sex or genotype had elevated blood urea nitrogen indicating reduced renal function and high parathyroid hormone (PTH). Micro-computed tomography of the distal femur revealed ~30% lower cortical thickness between wild-type Ad-CKD and wild-type control (CON) in both sexes. Cortical porosity was present in both sexes of wild-type Ad-CKD mice (average of 9.7% in male, 6.1% in females). Trabecular osteoclast-covered surfaces of the distal femur were ~3-fold higher in wild-type Ad-CKD mice compared to matched CON with corresponding higher bone formation rate. Ad-CKD mice lacking osteocyte RANKL had no statistical differences in cortical thickness or cortical porosity compared to sex- and genotype-matched CON groups with 3-6% differences in cortical thickness and cortical porosity values at or under ~2%. Additionally, Ad-CKD mice lacking osteocyte RANKL had no statistical differences in osteoclast-covered trabecular surfaces compared to matched CON groups. Likewise, there were no statistical increases in bone formation rate due to CKD in the transgenic Ad-CKD groups compared to matched controls. Overall, these data demonstrate that osteocyte RANKL is critical for the development of cortical porosity, cortical thinning, and high bone turnover seen in CKD with high PTH. Additionally, these data show that osteocyte RANKL is a key link between high circulating PTH and CKD-induced bone alterations. Anti-RANKL ligand

Induction of Osteocalcin+ Osteoblast Apoptosis Stimulates Paradoxical Bone Formation Via Osteoprogenitor Recruitment *LENA BATOON[4], AMY KOH[2], Laurie McCauley[3], Hernan Roca[4]. [4]University of Michigan, [2]U OF MICHIGAN, United States. [3]University of Michigan School of Dentistry, United States. [4]University of Michigan, United States

Billions of cells in the body undergo apoptosis daily - a crucial process for tissue homeostasis and organ development. In bone, osteoblasts routinely undergo apoptosis yet the relevance of this process remains underexplored. We generated a murine model with conditional expression of inducible caspase-9 (iCasp9) activated in the presence of Cre. Caspase-9 is an apoptosis-initiating enzyme and iCasp9 activity can be induced via a dimerizer (AP). To generate mice with inducible osteocalcin(OCN)+ osteoblast apoptosis, iCasp9 mice were crossed with OCNcre. OCNcre-iCasp9 mice at 3 weeks were injected intraperitoneally with AP or vehicle. Immunofluorescence of the vertebrae confirmed an increase in cleaved caspase-3+ apoptotic cells at 9h ($p<0.05$) and reduction in OCN+ osteoblasts at 24h ($p<0.01$) post AP injection, validating the model. Long-term AP treatment for 5 weeks induced a paradoxical increase in vertebral bone volume fraction ($p=0.0001$) irrespective of gender. Dynamic histomorphometry with calcein and xylenol orange injected at 7 and 2 days pre-harvest revealed that AP treatment enhanced bone formation rate ($p<0.05$) and mineral apposition rate ($p<0.05$). There was no change in TRAP+ osteoclasts or serum N-terminal telopeptide of type I collagen, indicating that the bone accrual was not due to changes in bone resorption. Increase in fractional bone volume did not translate in improved mechanical strength examined via compression testing likely due to disruption of the lacunocanalicular network. Long-term AP treatment increased empty osteocyte lacunae along with reduced canaliculi number and length. The number of sclerostin-expressing osteocytes was unaltered. To further understand the cellular mechanism, we stained for the pre-osteoblast growth factor amphiregulin (AREG) and osteoprogenitor markers osterix (OSX) and alpha-smooth muscle actin (?SMA). Induction of OCN+ cell apoptosis was associated with elevated AREG expression ($p<0.05$) and OSX+ cells in the bone marrow ($p<0.05$). ?SMA+ cells directly associated with bone surfaces were also increased ($p<0.01$). Interestingly, a similar long-term AP treatment regimen in OSXcre-iCasp9 mice did not trigger the bone increase observed with OCNcre-iCasp9 mice. Collectively, this work establishes the importance of osteoblast apoptosis in promoting osteoprogenitor recruitment and bone accrual. Importantly, it exposes the potential of targeting this mechanism to promote bone formation in the clinical setting.

Stat3 Persistent Activation in Osteoblasts Leads to High Bone Mass in Mice *Mariana Moraes de Lima Perini[1], Elizabeth Scott[2], Olivia Reul[2], Hong Du[3], Cong Yan[3], Jiliang Li[1]. [1]Department of Biology, Indiana University Purdue University Indianapolis, United States. [2]Department of Biomedical Engineering, Indiana University Purdue University Indianapolis, IN 46202, United States. [3]Department of Pathology and Laboratory of Medicine, Indiana University School of Medicine, IN 46202, United States

Signal Transducer and Activator of Transcription 3 (Stat3) plays an important role in bone formation and maintenance. Our previous studies have shown that osteoblast-specific deletion of Stat3 decreased bone mineral density (BMD) and strength. While overexpression of Stat3 in osteoblasts may increase osteogenic potential, overexpression of Stat3 in many other cell-types is associated with a wide range of cancers including prostate, breast cancer, etc. Stat3 overexpression is found throughout the tumor ecosystem in these cancers, in tumor cells, immune cells, and cancer-associated fibroblasts. To assess the consequences of Stat3 persistent activation in osteoblasts, we bred Osterix-tTA,tetO-EGFP/cre mice with CCSP-rtTA/(tetO)7-Stat3C bitransgenic mice to generate a doxycycline-controlled Osterix-tTA,tetO-EGFP/cre and Stat3c binary transgenic mouse model that over-expresses Stat3C (the constitutively active form of Stat3) selectively in osteoblasts lineage (OB-Stat3C mice). At 20 weeks of age, both male and female OB-Stat3C mice showed a significant increase in BMD and bone mineral content (BMC) compared to their littermate controls. Micro-CT analysis of the distal femur showed a significant increase in trabecular bone volume (520%; 882%), BV/TV (245%; 485.9%), trabecular number (174.5%; 257%), and trabecular thickness (26.7; 69.6%) for both male and female OB-Stat3C mice, respectively, when compared to their respective controls. Both histological images and micro-CT 3D reconstruction images (Figure 1) showed an excessive growth of trabecular bone not only in the distal part of the femur, but through the entirety of the femurs in both male and female OB-Stat3C mice. Bending tests of the femurs of male OB-Stat3C mice showed a significant increase of 119.77% in failure force while their females counterparts showed a significant increase of 55.22% compared to their respective controls. Furthermore, we did not observe any primary bone tumors even in 18-month-old mice. More importantly, we observed astonishing amounts of newly formed lamellar bone in the bone marrow of those mice, suggesting that Stat3 in osteoblasts and osteocytes not only stimulate lamellar bone formation but also does not induce tumor growth.

miR-219a-5p Improves Bone Mass in Mice and is Enriched in Osteoblast-derived Extracellular Vesicles *David Monroe[1], JAPNEET KAUR[2], Naureen Javeed[3], Madhusudhan Bobbili[4], Johannes Grillari[4], Joshua Farr[3], Jennifer Rowsey[3], Stephanie Vos[3], Ming Ruan[3], Sundeep Khosla[5]. [1]Mayo Foundation, United States. [2]University of Arkansas for Medical Sciences, [3]Mayo Clinic, United States. [4]Ludwig Boltzmann Institute for Traumatology, Austria. [5]Mayo Clinic College of Medicine, United States

We previously demonstrated that miR-219a-5p plays an osteo-anabolic role in cultured osteoblastic cells based on increased miR-219a expression during differentiation, enhancement of osteogenic marker expression with miR-219a mimics, and suppression of osteoblastic differentiation with a miR-219a antagonist. To test these effects in vivo, we developed a novel mouse model to express miR-219a under the control of a Cre-inducible system ("miR-219a-FLIP"). In the unrecombined state, the ubiquitous CAGGS promoter drives expression of EGFP, followed by an mCherry cassette with the miR-219a-5p sequence embedded in its 3' UTR in the reverse orientation (Fig 1A). Following Cre expression, a two-step recombination process results in loss of EGFP and expression of mCherry and miR-219a (Fig. 1B). We used the Actb-Cre to express miR-219a in all tissues and analyzed the bone phenotype at 4 months of age. We found significant ($p<0.05$) increases in BV/TV (+23%) and Tb.Th (+8%), with a trend for increased Tb.N. (+12%), in female mice at the spine. At the femur, significant increases in BV/TV (+46%) and Ct.Th (+7%) were observed, with a trend for increased Ct.Th (+4%). Similar trends were found in male mice. Osteoclast number was 2.9-fold decreased with no change in osteoblast number or activity, suggesting an anti-resorptive phenotype. We also found that miR-219a was present in EVs isolated from mouse calvarial osteoblasts. To validate this finding in vivo, we developed another novel mouse model where we could tag EVs from a select cell- or tissue-type using Cre mouse models. Using a similar design as in the miR-219a-FLIP model, we developed the "CAGS-SNORKEL" model where the SNORKEL protein (encoding a fusion of the EV-associated CD81 tetraspanin with various epitope tags) is expressed upon exposure to Cre. This model was crossed with either Prx1-Cre (early osteoblast progenitors) or Osteocalcin-Cre (late osteoblast/osteocyte), SNORKEL+ EVs isolated from bone marrow plasma using a magnetic bead protocol, and miRNA-seq performed. We found that miR-219a was enriched in osteoblast-derived EVs,

suggesting that miR-219a may perform its bone anabolic function, in part, through EV-mediated mechanisms. Cell culture studies further demonstrated that miR-219a increased Wnt activity through targeting of the Wnt inhibitor, Gsk3?. In summary, our data demonstrate that miR-219a is bone anabolic in vivo and may stimulate Wnt activity in bone using EV-mediated mechanisms.

Dual inhibition of sclerostin and Notum induces synergistic osteoanabolic action in mice *Roy Byung-Jun Choi[1], Alexander Robling[1], Jung Min Hong[2]. [1]Indiana University School of Medicine, United States. [2]Indiana University School of Dentistry, United States

The Wnt pathway has been an obvious target for designing skeletal therapies, mainly based on the Wnt inhibitor sclerostin. The sclerostin-neutralizing agent romosozumab was recently approved to treat patients at increased fracture risk. However, significant adverse events were found in clinical trials, prompting the FDA to assign a 'black-box warning' to patients at higher risk for cardiovascular complications. Thus, reducing the dose of sclerostin antibody while maintaining the anabolic potential of the drug will likely provide a safer and more cost-effective strategy to harness Wnt for fracture prevention. Previously, we reported that simultaneous pharmacological or genetic inhibition of the Wnt antagonists sclerostin and Dkk1 could be optimized to create potentiated effects in the cancellous bone compartment. This highly efficacious approach allowed significantly reduced drug dose yet maintained full (or improved) anabolic potential. We looked for other candidates that might be co-inhibited along with sclerostin to potentiate effects in the cortex. To start, we used genetic clues for molecules that preferentially affect the cortical compartment. Another Wnt inhibitor that has major effects on cortical but not cancellous bone is Notum, a secreted deacylase that removes palmitoylated modifications from Wnt ligands, thereby neutralizing Wnt's ability to interact with Fzd-Lrp5/6. Previously, we found Notum deletion mice had an additive effect on cortical bone formation in the absence of sclerostin. We looked at Notum as target to inhibit, alongside sclerostin, to improve cortical bone specifically. We generated double knockout mice in both Sost and Notum (Sost-/-;Notum-/-) and compared them to single knockouts and WT controls. Further, we performed analogous experiments with pharmacologic inhibitors, rather than genomic mutations. i.e., co-treatment of WT mice with sclerostin antibody and a small molecule inhibitor of Notum (LX-5061). Each experiment included evaluation by DXA-derived radiography, μCT, biomechanical testing and bone dynamic histomorphometry to assess the distal and midshaft femur, and lumbar vertebrae. Inhibition/deletion of Notum alone had mild cortical effects while co-suppressing/deleting sclerostin and Notum significantly improved bone mass and strength. Pharmacologic studies largely supported the genetic studies, suggesting that co-inhibiting sclerostin and Notum might be viable for treating low bone-mass disease in aged patients.

PTH regulates osteogenesis and suppresses adipogenesis through Zfp 467 in a feed-forward, PTH1R-cyclic AMP-dependent manner *Hanghang Liu[1], Phuong T. Le[1], Akane Wada[2], Isabella Le[1], Andrew Lee[1], Jun Zhou[2], Francesca Gori[2], Roland Baron[2], Clifford J. Rosen[1]. [1]MaineHealth Institute for Research, United States. [2]Harvard School of Dental Medicine, United States

Conditional deletion of the PTH1R in mesenchymal progenitors reduces osteoblast differentiation, enhances marrow adipogenesis and increases zinc finger protein 467 (Zfp467) expression. In contrast, genetic loss of Zfp467 increased Pth1r expression and shifts mesenchymal progenitor cell fate towards osteogenesis and higher bone mass. In this study, we hypothesized PTH1R and ZFP467 could constitute a feedback loop that facilitates PTH-induced osteogenesis and that conditional deletion of Zfp467 in osteogenic precursors would lead to high bone mass in mice. Similar to global Zfp467-/- mice that have significantly higher bone formation and bone volume assessed by ?CT and histomorphometry analysis, Prrx1Cre; Zfp467fl/fl but not AdipoqCre; Zfp467fl/fl mice exhibit high bone mass and greater osteogenic differentiation similar to the Zfp467-/- mice. qPCR results revealed that PTH suppressed Zfp467 expression primarily via the cyclic AMP/PKA pathway. Not surprisingly, PKA activation inhibited the expression of Zfp467 and gene silencing of Pth1r caused an increase in Zfp467 mRNA transcription. Dual fluorescence reporter assays and confocal immunofluorescence demonstrated that genetic deletion of Zfp467 resulted in higher nuclear translocation of NF?B1 that binds to the P2 promoter of the Pth1r and increased its transcription. As expected, NF?B1 was found heterodimerize with RelB to transactivate the transcription of Pth1r, higher protein level of NIK and activated non-canonical NF?B pathway was also observed in Zfp467 deficient osteoblasts. In addition, Zfp467-/- cells had enhanced production of cyclic AMP and increased glycolysis in response to exogenous PTH. And the osteogenic response to PTH was also enhanced in Zfp467-/- calvarial osteoblasts, and the pro-osteogenic effect of Zfp467 deletion was blocked by gene silencing of Pth1r or a PKA inhibitor. In conclusion, our findings suggest that loss or PTH1R-mediated repression of Zfp467 results in a pathway that increases Pth1r transcription via NF?B1 and thus cellular responsiveness to PTH/PTHrP, ultimately leading to enhanced bone formation.

Spatial transcriptomic analysis of a pre-clinical model of Nf1-deficient fractures pseudarthrosis *Jonathan Rios[1], Yared Kidane[1], Conan Juan[2], Carol Wise[3], Robert Tower[4]. [1]Scottish Rite for Children, United States. [2]UTSouthwestern Medical Center, United States. [3]Texas Scottish Rite Hospital, United States. [4]University of Texas Southwestern Medical Center,

Patients with Neurofibromatosis type 1 (NF1) may develop fracture pseudarthroses characterized by a persistent fibrotic, hypomineralized callus with a high re-fracture risk. Prior pre-clinical studies demonstrated impaired osteogenic potential of cultured periosteal and bone marrow progenitor cells in vitro. Delayed fracture healing phenocopying patient pseudarthrosis has been demonstrated in Postn-cre;Nf1flox/- (herein Nf1Postn) mice; however, molecular analyses of such delayed fracture healing is lacking.Spatial transcriptomics provides unprecedented resolution of cell type-specific gene expression profiling within the context of normal and diseased tissues. Here, we performed spatial transcriptomic analyses of fracture calluses from Nf1Postn and control mice. Spatial transcriptomic analysis was performed on control and Nf1Postn calluses 10 days after distal tibia osteotomy fracture using the 10X Genomics mouse FFPE Visium protocol.Spatial transcriptomic analysis detected a median 2,168 and 2,203 expressed genes per spot under tissue, with an average 4,315 and 4,631 unique molecular identifiers (UMI) per spot from 61,642 and 85,469 mean reads per spot, respectively. Graph-based clustering analysis detected eight tissue/cell types mapping to the fracture calluses, each with associated expression biomarkers that informed their predicted identities. Gene set enrichment analysis (GSEA) demonstrated significantly increased expression of pathways involved in cartilage development and chondrocyte differentiation (Cartilage), collagen deposition in the extracellular matrix (Ossifying perichondrium), and bone remodeling and biomineralization (Woven bone) within spatial clusters. Additionally, expression of genes representative of different morphogenetic pathways, such as BMP, TGF-?, and WNT, were spatially restricted within the fracture callus. Finally, GSEA analysis demonstrated reduced expression of pathways required for proper skeletal development and fracture healing, including BMP signaling, chondrogenesis, cartilage development, extracellular matrix, and bone remodeling pathways, in the Nf1Postn fracture compared to control. This study is the first to apply unbiased spatial transcriptomic analysis to resolve molecular gradients within a fracture callus and to spatially resolve molecular dysregulation leading to delayed fracture healing in a pre-clinical disease model.

Microbiome-Induced Intestinal Th17 Cells and Musculoskeletal ?? T Cells Improve Fracture Healing *Hamid Y Dar[1], Daniel Perrian[1], Subhashis Pal[1], Andreea Stoica[1], Sasidhar Uppuganti[2], Jeffry S Nyman[2], Rheinallt M Jones[1], M. Neale Weitzmann[1], Roberto Pacifici[1]. [1]Emory University, United States. [2]Vanderbilt University Medical Center, United States

IL-17 is a driver of the inflammatory phase of fracture repair. This cytokine is produced in the callus by ?? T cells and Th17 cells. However, the origin of the ?? T cells and Th17 cells involved in fracture repair, the mechanism by which they are home to the callus, and their contribution to fracture healing are unknown. Using a model of murine femoral fracture that heals by endochondral ossification, we found that femoral fractures were followed within 2- days by an expansion of callus ?? T cells. Their activation and release of IL-17 caused systemic inflammation and increased gut permeability. Demonstrating the relevance of ?? T cells, fractures did not increase gut permeability and fracture repair was delayed in TCRd-/- mice, a strain lacking ?? T cells. When the gut microbiota contained the Th17 cell-inducing taxa segmented filamentous bacteria (SFB), increased gut permeability led to the expansion of intestinal Th17 cells, higher callus levels of IL-17 with a peak at day 3- after fracture, and faster fracture repair. Studies using Kaede mice, a strain expressing a photo-convertible fluorescent protein that allows direct tracking of intestinal lymphocytes, demonstrated that fractures increased by ~ 3 folds the migration of intestinal Th17 cells to the callus with a peak at day 3. These studies also showed the existence of a small pool of microbiome-induced intestinal ?? T cells that migrate to the callus. IV injection of eGFP+ Th17 cells confirmed that fractures increased the tropism of Th17 cells toward the callus. Mechanistically, fractures increased the S1P-receptor-1 (S1PR1) mediated migration of Th17 cells from the intestine to the bloodstream. In addition, fractures increased the homing of circulating Th17 cells to the callus by upregulating the expression by callus stromal cells of CCL20, a ligand for the chemokine receptor CCR6 expressed by Th17 cells. Attesting to the relevance of these mechanisms, the fracture-induced increase in callus IL-17 levels was prevented, and fracture repair was impaired, by the deletion of ?? T cells, depletion of the microbiome by antibiotics, and lack of SFB in the gut microbiome. These findings demonstrated the relevance of the gut microbiome, ?? T cells, and Th17 cell trafficking for fracture repair. Modifications of microbiome composition via Th17 cell-inducing bacteriotherapy and avoidance of broad-spectrum antibiotics may represent novel therapeutic strategies to improve fracture healing.

Microbiome-Induced Intestinal Th17 Cells and Musculoskeletal γδ T Cells Improve Fracture Healing

IL-17 is a driver of the inflammatory phase of fracture repair. This cytokine is produced in the callus by γδ T cells and Th17 cells. However, the origin of the γδ T cells and Th17 cells involved in fracture repair, the mechanism by which they are home to the callus, and their contribution to fracture healing are unknown. Using a model of murine femoral fracture that heals by endochondral ossification, we found that femoral fractures were followed within 2- days by an expansion of callus γδ T cells. Their activation and release of IL-17 caused systemic inflammation and increased gut permeability. Demonstrating the relevance of γδ T cells, fractures did not increase gut permeability and fracture repair was delayed in TCRd-/- mice, a strain lacking γδ T cells. When the gut microbiota contained the Th17 cell-inducing taxa segmented filamentous bacteria (SFB), increased gut permeability led to the expansion of intestinal Th17 cells, higher callus levels of IL-17 with a peak at day 3- after fracture, and faster fracture repair. Studies using Kaede mice, a strain expressing a photo-convertible fluorescent protein that allows direct tracking of intestinal lymphocytes, demonstrated that fractures increased by ~ 3 folds the migration of intestinal Th17 cells to the callus with a peak at day 3. These studies also showed the existence of a small pool of microbiome-induced intestinal γδ T cells that migrate to the callus. IV injection of eGFP+ Th17 cells confirmed that fractures increased the tropism of Th17 cells toward the callus. Mechanistically, fractures increased the S1P-receptor-1 (S1PR1) mediated migration of Th17 cells from the intestine to the bloodstream. In addition, fractures increased the homing of circulating Th17 cells to the callus by upregulating the expression by callus stromal cells of CCL20, a ligand for the chemokine receptor CCR6 expressed by Th17 cells. Attesting to the relevance of these mechanisms, the fracture-induced increase in callus IL-17 levels was prevented, and fracture repair was impaired, by the deletion of γδ T cells, depletion of the microbiome by antibiotics, and lack of SFB in the gut microbiome. These findings demonstrated the relevance of the gut microbiome, γδ T cells, and Th17 cell trafficking for fracture repair. Modifications of microbiome composition via Th17 cell-inducing bacteriotherapy and avoidance of broad-spectrum antibiotics may represent novel therapeutic strategies to improve fracture healing.

Dysregulation of the Unfolded Protein Response Outputs by Diet-Induced Obesity may Impede Fracture Repair. *Lakshmi Kolora[1], Sara Higsley[1], Dana Godfrey[1], Kartik Shankar[2], Douglas Adams[3], SRIVIDHYA IYER[4]. [1]Department of Orthopedics, University of Colorado Anschutz Medical Campus, United States. [2]Department of Pediatrics, University of Colorado, Anschutz Medical Campus, United States. [3]University of Colorado, United States. [4] Univ of Colorado, Anschutz Medical Campus, United States

Obesity increases skeletal fragility and hinders fracture repair in humans and rodent models, but its biological basis is unknown. Endoplasmic reticulum (ER) stress, due to protein processing deficits, mediates development of obesity-related comorbidities including diabetes, but its contribution in the context of bone repair remains unaddressed. The Unfolded Protein Response (UPR) engages transcriptional (IRE1/XBP1s and ATF6) and translational (PERK) outputs that aid protein folding and transiently repress protein synthesis, respectively, to relieve ER stress. To comprehensively assess the UPR during fracture repair in obese backgrounds, 17-week-old diet-induced obese (DIO) and DIO control mice (Jax Labs) were administered tibial fracture by osteotomy. DIO mice exhibited lower callus bone volume (~32 %), strength (~35 %), and stiffness (~33%) at 28 days post-fracture (dpf). DIO suppressed expression of osteogenic (RunX2, Sp7, Col1a1) genes and augmented adiposity (Fabp4, Ppar?) in cultures of 10dpf callus. Notably, obesity also inhibited the expression of several IRE1/XBP1s targets in callus cultures, concomitant with apoptosis. The ATF6 protein levels were, however, unaffected. Furthermore, callus culture lysates obtained from DIO mice exhibited elevated PERK activity, as evidenced by increase in phosphorylation of PERK and its downstream target eIF2?. The expression of Gadd34 (a phosphatase that reverses p-eIF2? phosphorylation) was suppressed, substantiating a protracted PERK-induced translational arrest. In line with these findings, single-cell profiling of 10 dpf callus revealed ~3-fold increase in bipotential Cxcl12-abundant reticular (CAR) cells with obesity. However, CAR cell-dependent endothelial, B-cell and neutrophil niches were decreased, but adipocytes were increased ~10-fold in the obese callus. Per gene ontology analyses, DIO was associated with suppression of protein synthesis processes and upregulation of inflammatory genes in CAR cells. Further confirming a role for aberrant UPR in skeletal repair deficits, the ER stress attenuator TUDCA mitigated the HFD-induced low callus bone volume, and rescued the osteo to adipocytic skewing of the callus transcriptome. Our findings demonstrate that obesity dysregulates PERK and IRE1/XBP1s outputs during osteogenic fracture repair, a phase reliant on protein synthesis and processing, and underscores the potential of modifying the UPR to improve fracture repair in obese diabetic populations.

YAP regulates periosteal progenitor cell proliferation through both cell intrinsic and extrinsic co-transcriptional programs *MADHURA NIJSURE[2], Annemarie Lang[2], Elizabeth Seidl[2], Christopher Panebianco[2], Miriam Baitner[2], Gabrielle Tanner[2], Dakota Jones[2], Annapurna Pranatharthi-Haran[2], Greg Szeto[3], Nathaniel Dyment[2], Joel Boerckel[2]. [2]University of Pennsylvania, . [2]University of Pennsylvania, United States. [3]Seagen Inc, United States

Bone fracture repair activates the transcriptional regulator, YAP, in periosteal cells and initiates periosteal cell proliferation. Deletion of YAP, and its paralog TAZ, from Osterix-expressing cells impairs periosteal cell proliferation and periosteal expansion1. The transcriptional mechanisms by which YAP drives periosteal expansion are unclear. YAP does not directly bind to DNA but forms a complex with other transcription factors to regulate transcriptional activity. It is therefore important to identify both YAP transcriptional programs and the associated transcription factor partners.To this end, we used a gain-of-function model to induce expression of constitutively active YAP (YAPS127A) upon treatment with doxycycline. We isolated periosteal cells from 4-day old fracture calluses and treated them with 1?M doxycycline in vitro. We performed orthogonal Bulk mRNA sequencing (RNA-seq) and Assayed for Transposase Accessible Chromatin with sequencing (ATAC-seq) to quantify YAP-induced messenger RNAs and YAP-regulated chromatin accessibility, respectively. This analysis identified YAP target genes and putative transcription factor binding partners in periosteal cells.Gene set variation analysis revealed 236 gene sets most relevant to progenitor pool expansion during fracture repair (Fig 1A). YAPS127A activation significantly enriched gene sets involving cell cycle progression and Smad2/3 signaling and suppressed gene sets marking caspase pathways involved in apoptosis. Specifically, YAPS127A upregulated both cell intrinsic factors, such as Cdk6, and cell extrinsic or secreted factors, such as Bmp4 and Cyr61. Analysis of DNA motifs present in differentially accessible chromatin revealed enrichment of chromatin loci containing the consensus binding motifs of the TEAD and Smad2/3 transcription factors (Fig 1B). YAPS127A activation elevated canonical YAP-TEAD complex target genes and enriched Smad2/3-target gene sets, supporting roles for both TEAD and Smad2/3 as putative transcriptional co-effectors of YAP in periosteal osteoblast precursors. We further validated YAP-TEAD binding in periosteal cells by immunoprecipitating YAP and probing for TEAD (Fig 1C).Finally, to define the impact of YAP/TAZ signaling on cell proliferation in vivo, we deleted YAP/TAZ from Osterix expressing cells in mice. There was a significant decrease in proliferation and cell numbers of both Osterix-targeted cells and non-targeted cells, confirming that YAP/TAZ signaling functionally regulates periosteal progenitor proliferation through both cell intrinsic and extrinsic mechanisms (Fig 1D).Together, these data reveal that YAP and TAZ regulate proliferation-associated gene

expression partially through TEAD and promote functional periosteal expansion for fracture repair.References:1. Kegelman+, JBMR 2020

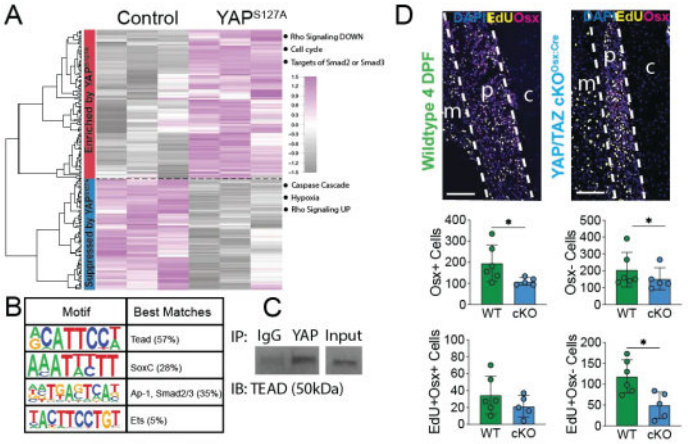

Figure 1. A. Gene Set Variation Analysis revealed 236 differentially regulated gene sets after YAP^{S127A} expression. **B.** TEAD Binding motifs were 57% enriched in open chromatin in YAP^{S127A} expressing cells. **C**. TEAD co-immunoprecipitates with YAP in periosteal cells. **D**. Neutrophil-derived TGF?1 causes age-related osteoporosis and delays fracture healing *Han Jiao[1], Jinxiao Fan[1], Shida He[1], Brendan Boyce[2], Jinbo Li[1]. [1]Hebei Medical University, China; [2]University of Rochester Medical Center, United States

During aging, enhanced myeloid lineage commitment promotes neutrophil generation, but neutrophil effects on bone homeostasis remain poorly understood. We generated Ly6G-CreERRosaDTA (Ly6G-DTA) mice in which tamoxifen induced diptheria toxin expression in neutrophils (Ly6G+) and caused specific ablation of >99% neutrophils in BM. Of note, femoral trabecular bone mass, thickness, number and mineral density in adult (8-mon-old) Ly6G-DTA mice were significantly higher than in WT littermates (BV/TV: 44.8+/-3.2% vs 22.1+/-2.0% in WT mice; p<0.001), associated with markedly increased bone formation and bone resorption, but cortical thickness was normal. Transplant of Ly6G-DTA mouse BM cells into 2-mon-old immunodeficient NSG mice caused a significant increase in trabecular bone mass and mineral density, suggesting that Ly6G+ neutrophils negatively regulate bone mass. TGF?1+CCR5+ neutrophil numbers increase in BM during aging and cause bone loss. Single-cell RNA-Seq data revealed that TGF?1+ neutrophils are a terminally differentiated subset in which pro-osteoclast differentiation signaling was highly activated and associated with high Il-1? and Dap12 transcription. To further determine the role of neutrophil-derived TGF?1 on bone aging, we next generated Ly6GCreERTGF?1fl/fl (TGF?1-cKO) mice and found that inducible deletion of Tgf?1 from Ly6G+ neutrophils caused significant decrease in TGF?1 protein levels in BM and impairment of neutrophil NET formation and phagocytosis. In addition, TGF?1-cKO mice have higher trabecular bone mass (BV/TV: 45.2+/-6.2% vs 22.1+/-2.0% in WT mice; p<0.001) and mineral density (BMD: 1.07+/-0.19 vs 0.40+/-0.07 g/cm3 in WT mice; p<0.001) than WT littermates, associated with markedly increased bone formation and resorption, similar to Ly6G-DTA mice. RNASeq analysis of tibial fracture callus of 4- (young) and 20-mon-old (aged) mice revealed that neutrophil chemotaxis and TGF? signaling pathways were more highly activated in aged callus. Notably, callus and woven bone volume were higher in Ly6G-DTA and TGF?1-cKO mice than WT littermates at 2-, 3- and 4-week post fracture (Woven bone: 5.2+/-1.9 mm3 in DTA, 5.3+/-1.6 mm3 in TGF?1-cKO vs 2.3+/-0.4 mm3 in WT mice; p<0.01), associated with increased bone formation and decreased callus fibrosis. These findings define novel roles of neutrophils and neutrophil-derived TGF?1 in bone homeostasis and fracture repair; blockade of neutrophils or TGF?1 might prevent age-related osteoporosis and enhance fracture repair.

ObjectivesHypophosphatasia (HPP) is an inherited multisystem disorder predominantly affecting the mineralization of bones and teeth. HPP is caused by pathogenic variants in ALPL, which encodes tissue non-specific alkaline phosphatase. A major challenge in diagnosing HPP is interpreting variants in ALPL classified as variants of uncertain significance (VUS) according to ACMG/AMP criteria, creating uncertainty in patients and treating physicians resulting in diagnostic delays. The ALPL gene variant classification project was established to reclassify VUS and to continuously assess and update genetic, phenotypic, and functional variant information in the ALPL gene variant database (https://alplmutation-database.jku.at/), an open-access archive for interpretations of the clinical significance of variants reported in ALPL. We aim to report the first results of newly classified variants in this project.MethodsAn international, multidisciplinary consortium of HPP experts has been established to reclassify the submitted VUS using a multi-step process adhering to the ACMG/AMP variant classification guidelines. These steps include a clinical phenotype assessment, deep literature review including artificial intelligence technology, molecular genetic assessment, and in-vitro functional testing (episomal pcDNA3 vectors used in a co-transfection model to express a variant in renal MDCK-II cells to measure ALP residual activity and assess dominant negative effect).ResultsCurrently, the ALPL database has 429 variants and 594 genotypes. The number of VUS reclassified or classified by the ALPL gene consortium since its inception in Feb 2021 is 58, as shown in the table below.VariantsNumber of VariantsReclassified to date58-Reclassified with functional testing-Reclassified from literature2813New submissions classified20Out of the 58 classified or reclassified variants, 4 were pathogenic, 29 likely pathogenic, 2 were likely benign, 1 benign, and 21 remained VUS. 84 new genotypes and 57 new phenotypes were added to the variants in the ALPL database.Through studying the submitted and reported phenotypes, we discovered distinct new phenotypes - asymptomatic heterozygote individuals featuring the typical biochemical signature of HPP (c.1225C>T, c.466C>T, c818C>T, c.244G>A, c.244G>C, c.906C>A, c.83A>G and c.299C>T) and heterozygote individuals with massive ectopic calcification (c.1559del and c.1250A>G).ConclusionThis classification project and the ALPL gene variant database serve the global medical community and widen the genotypic and phenotypic HPP spectrum by classifying ALPL variants based on ACMG/AMP criteria, thus facilitating improved genetic counselling and medical decision-making for affected patients and families and as a repository for clinicians and scientists to query a variant and view evidence of its pathogenicity.

Development of bone targeted anti-TGF? antibody for the treatment of osteogenesis imperfecta *I-Wen Song[1], Dianne Nguyen[1], Alyssa Tran[1], Ben Greene[2], James Cao[2], Xiaoyou Ying[2], Anna Park[2], Elizabeth Masterjohn[2], Denise Honey[2], Shiguang Liu[2], Sandesh Nagamani[1], Brendan Lee[1]. [1]Baylor College of Medicine, United States; [2]Sanofi, United States

Osteogenesis imperfecta (OI) is a genetic skeletal disorder for which, currently, there are no FDA-approved therapies. We, and others, have previously shown that excessive TGF? signaling is a key pathogenic driver in OI and that inhibition of TGF? could be a potential mechanism-specific approach for treatment. In a phase 1 study with fresolimumab, an anti-TGF? antibody, we found that individuals with moderate OI, i.e., OI type IV had increase in lumbar spine areal bone mineral density whereas individuals with the more severe forms, i.e., OI types III and VIII did not. This suggested a dose-specific effect based on disease severity that correlates with treatment studies in preclinical models of OI of varying severity. Here, we report on the pharmacodynamics and pharmacokinetics of fresolimumab and preliminary results in generating a bone-targeted anti-TGF? antibody to improve efficacy and safety. We found that peak plasma levels of fresolimumab were higher in individuals with

OI who received 4 mg/kg dose compared to 1 mg/kg. The plasma levels dropped to 84% of the peak level by day 15 and returned to baseline by day 90. Overall, an anabolic window, i.e., lower CTX and higher P1NP levels as compared to baseline values, were observed in 4 out of 8 participants. In the 4 mg/kg cohort, suppression in bone turnover marker osteocalcin was observed at day 30 and 180 together with an anabolic window. This alluded to the possible need for a higher anti-TGF? concentration in OI bone. Therefore, we generated a bone-targeted anti-TGF? antibody, 1D11-D10. After a single dose administration in WT mice, 1D11-D10 showed increased distribution to bone (lumbar and femur) and reduced concentrations in plasma, kidney and heart as compared to untargeted 1D11. Moreover, 1D11-D10 has a longer half-life of 76 days in bone compared to 16.3 days for 1D11 (t1/2 ratio=4.7). Importantly, at 0.3, 1, and 5 mg/kg 3 times/week dosing of Col1a2G610C/+ OI mice, 1D11-D10 showed comparable effect on bone mass at 1mg/kg and a trend towards higher efficacy at 5mg/kg comparing to untargeted 1D11. These data supported the effective bone targeting and a potential increased efficacy and safety profile for 1D11-D10. As bone targeted anti- TGF? therapy may offer wider therapeutic index, this may be important for clinical translation in OI and other skeletal diseases with TGF? dysregulation.

Standard bone microarchitecture assessment using HR-pQCT in adults with Osteogenesis Imperfecta: does it tell the whole story? *MELISSA BEVERS[1], Arjan Harsevoort[2], Koert Gooijer[2], Caroline Wyers[3], Hans Feenstra[2], Bert Rietbergen[4], Joop Van Den Bergh[5], Guus Janus[2]. [1]VieCuri Medical Center, [2]Expert Center for adults with Osteogenesis Imperfecta Isala Hospital, Netherlands, [3]VieCuri Medical Centre, Netherlands, [4]Eindhoven University of Technology, Netherlands, [5]VieCuri MC Noord-Limburg and Maastricht UMC,

Purpose: Osteogenesis imperfecta (OI) is a heterogenous disorder associated with bone fragility. In an ongoing study, we observed inhomogeneities in the trabecular compartment on high-resolution peripheral quantitative CT (HR-pQCT) scans, which potentially influence standard HR-pQCT analyses. The aim of this study was to assess bone microarchitecture in adults with OI using HR-pQCT and to evaluate whether inhomogeneities in the microarchitecture are captured by or influence standard HR-pQCT parameters. Methods: Limb-length dependent HR-pQCT scans of the distal radius and tibia were obtained from 118 adults with OI (41.8 [interquartile range (IQR): 25.1] year old). Cortical and trabecular microarchitecture were quantified using standard HR-pQCT analyses and compared to normative data from literature (Warden et al. Osteoporos Int 2021). Scans were also visually evaluated. Results: 91 radius and 91 tibia scans were analyzed after exclusion of scans with insufficient quality or deviating axial scan angles. At the radius, trabecular number (Tb.N) was low (Z-score: -2.5+/-1.4), and trabecular separation (Tb.Sp) was high (Z-score: -2.7 [2.7]). Trabecular thickness (Tb.Th), cortical thickness (Ct.Th), and cortical porosity (Ct.Po) deviated less from the normative data. 12% and 31% of the patients had a Z-score <-4 for Tb.N and Tb.Sp, respectively, and 0-3% had a Z-score 4 for Tb.Th, Ct.Th, and Ct.Po. The deviations from normative data were larger at the tibia. Void volumes of variable size were seen in the trabecular compartment, more often at the tibia and with corresponding highly negative Z-scores for Tb.N and Tb.Sp (Fig.1a). Local sclerotic spots and thickened trabeculae were also observed, mainly at the tibia and together or not with an increased Tb.Th (Fig.1b). A high Tb.Th was also seen in the absence of these thickened bone spots. In the cortex, locally increased porosity and reduced mineralization density were seen, mainly near the periosteum and not always fully captured by the standard HR-pQCT analyses (Fig.1c). Conclusion: The cortical and trabecular bone in adults with OI show local inhomogeneities. Standard HR-pQCT analyses do not give a complete impression of bone microarchitecture in OI and should be extended to better capture local inhomogeneities, e.g. by detection and evaluation of void volumes and local sclerotic regions in the trabecular bone and by evaluation of cortical and trabecular bone at a broader range of mineralization densities.

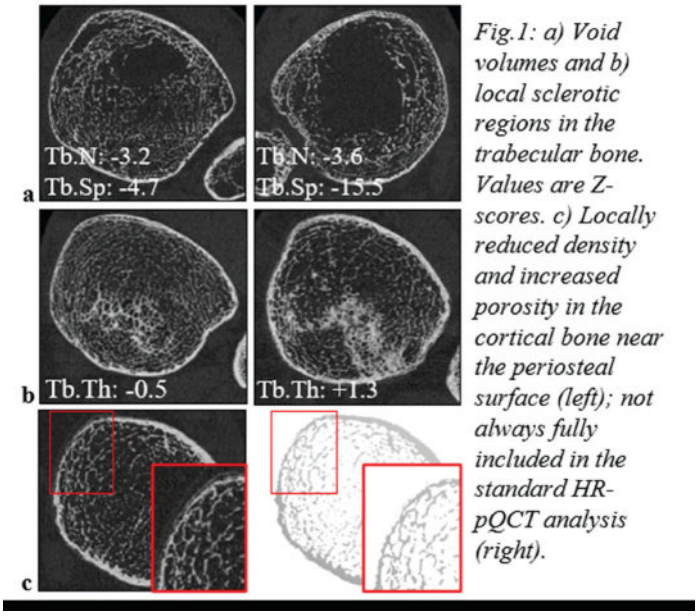

Fig.1: a) Void volumes and b) local sclerotic regions in the trabecular bone. Values are Z-scores. c) Locally reduced density and increased porosity in the cortical bone near the periosteal surface (left); not always fully included in the standard HR-pQCT analysis (right).

Purpose: Evaluate the temporal changes in and relationship between skeletal endpoints in response to palopegteriparatide (TransCon PTH), a prodrug with sustained release of PTH(1-34), in individuals with chronic hypoparathyroidism. Methods: PaTHway is a phase 3 trial of TransCon PTH with a randomized, placebo-controlled 26-week blinded period and 156-week open-label extension. Serum bone turnover markers (BTM) of bone formation (procollagen type 1 N-terminal propeptide [P1NP]) and bone resorption (C-telopeptide [CTx]) were assessed at baseline and weeks 12, 26, 38, and 52. Bone mineral density (BMD) was assessed by DXA at the lumbar spine, total hip, and distal 1/3 radius at baseline, weeks 26 and 52. Skeletal endpoints are reported herein for participants randomized to TransCon PTH with week 52 data (n=59). Results: At baseline, participants in the TransCon PTH group had a mean (SD) age of 49 (13) years; 75% were female, 41% of whom were postmenopausal. Through week 52, 81% (48/59) maintained normal serum calcium (8.3-10.6 mg/dL) and independence from conventional therapy (<=600 mg/day of elemental calcium and no active vitamin D). TransCon PTH treatment initially increased CTx and P1NP; responses peaked by week 12 and 26, respectively, and then declined through week 52 (Fig). From weeks 26 to 52, BTM decreased most in those with the highest values at week 26. Mean baseline BMD was high, as expected in hypoparathyroidism. With exposure to TransCon PTH over 52 weeks, mean BMD Z-scores and T-scores declined from above 0 toward age- and/or sex-matched norms at the lumbar spine and total hip, with a smaller magnitude of change from week 26 to 52 (Fig). Changes in BMD at the spine and hip were consistent across age, sex, and postmenopausal status, and at week 26 were inversely correlated with changes in P1NP and CTx at week 12 (R: -0.23 to -0.48). Conclusions: TransCon PTH treatment resulted in mobilization of calcium from the low bone turnover state in adults with hypoparathyroidism. Increases in BTM were correlated with declines from disease-elevated BMD at baseline. After week 26, BTM normalized toward sex and menopausal status appropriate levels and corresponded to lesser declines in BMD through week 52, similar to the results through week 110 in the Phase 2 PaTH Forward trial. These 52-week results reflect temporal changes trending toward a new skeletal steady state closer to age-appropriate norms with continued use of TransCon PTH in hypoparathyroidism.

[2]AP-HP, Endocrinology and diabetes for children, Reference center for rare diseases of the Calcium and Phosphate Metabolism, DMU SEA, OSCAR filière, EndoRare and BOND ERN, Bicêtre Paris Saclay Hospital, France. [3]Université Paris Cité, Laboratory Orofacial Pathologies, Imaging and Biotherapies URP2496 and FHU-DDS-Net, Dental School, and Plateforme d'Imagerie du Vivant (PIV), Montrouge, France

Background/aim: Hyperparathyroidism (HPHT) is a common feature in patients with X-linked hypophosphatemia (XLH) especially when treated with vitamin D analogues and phosphate supplements. Although the exact mechanism is not clear, it is assumed that phosphate supplements taken chronically stimulate parathyroid hormone (PTH) secretion. We prospectively assessed the effect of a novel pathogenetic treatment anti-FGF23 (burosumab) on PTH levels in children with XLH.Patients and methods: 37 XLH-children (23 girls / 14 boys; 8.8+/-3.2 years) were switched from conventional therapy to burosumab and completed at least three years of burosumab therapy. Subjects with secondary HPTH at baseline were excluded from analysis. The biochemical parameters of calcium-phosphate metabolism were measured at baseline (M0) and then every 6 months under burosumab (M6 up to M36). According to our national guidelines, the target serum phosphate upon burosumab was >1.2 mmol/l (>3.7 mg/dl). Results: After three years of treatment with burosumab, there was a global increase of PTH levels from 39.1+/-18.2 (M0) to 54.8+/-27.6 ng/l (M36) (18.5-88 ng/l) (p=0.001). Four subjects of 37 (10.8 %) developed secondary HPTH with mean+/-SD PTH levels equal to 110+/-17.9 ng/l. The subjects who developed HPTH tended to be older (10.0+/-1.2 vs 8.7+/-3.4 yrs, p=0.43, respectively) and had significantly higher PTH levels at baseline (62.8+/-22.5 vs 36.3+/-15.7 ng/l, p=0.004, respectively), in comparison to those without HPTH. Subjects with HPTH tended to have higher levels of serum phosphate at M36 (1.33 vs 1.19 mmol/l, p=0.11, respectively) and higher delta of phosphate increase from M0 to M36 (94% vs 63%, p=0.051, respectively), in comparison to those without HPTH. None of the children developed tertiary hyperparathyroidism. Conclusion:This is the first study describing the effect of anti-FGF23 treatment on PTH secretion in children with XLH. Although the benefit on phosphate homeostasis and bone mineralization has been fully demonstrated, we suggest that prolonged anti-FGF23 treatment may stimulate PTH secretion thus leading to development of hyperparathyroidism after three years of treatment. Nonetheless, longer follow-up study is needed to better understand and describe this phenomenon.

The serine synthesis pathway drives osteoclast differentiation through epigenetic regulation of NFATc1 expression *Steve Stegen[1], Karen Moermans[1], Ingrid Stockmans[1], Bernard Thienpont[2], Geert Carmeliet[1]. [1]Clinical and Experimental Endocrinology, KU Leuven, Belgium. [2]Laboratory for Functional Epigenetics, KU Leuven, Belgium

Mature osteoclasts display a specific metabolic profile, characterized by mitochondrial respiration to accommodate the bioenergetic demands of bone resorption, next to glycolysis that likely contributes to local acidification for dissolving bone mineral. However, whether metabolic adaptations are drivers of osteoclast differentiation or rather a consequence of an altered cellular state is poorly understood.Here, using mass spectrometry-based metabolomics and in vivo models, we identify the serine synthesis pathway (SSP) as a critical regulator of osteoclast differentiation. During early osteoclastogenesis, prior to NFATc1 induction, RANKL transiently activates the SSP, evidenced by enhanced 13C-glucose incorporation in serine and glycine, and increased expression of SSP enzymes. In contrast, mature osteoclasts relied more on serine and glycine uptake. The transient stimulation of the SSP is physiologically important, as deletion of the rate-limiting enzyme phosphoglycerate dehydrogenase (PHGDH) in osteoclast precursors (Lysozyme M-Cre) resulted in a high-bone-mass phenotype, caused by decreased bone resorption with no effect on bone formation. At the cellular level, the SSP is essential to initiate osteoclast differentiation, evidenced by a decrease in TRAP-positive osteoclasts and osteoclast-related gene expression in PHGDH-null cells, whereas proliferation or cell survival was not affected. As a mechanism, we found that the SSP-enzyme phosphoserine aminotransaminase 1 generates ?-ketoglutarate (?KG), which in turn stimulates ?KG-dependent demethylases that remove the repressive histone mark H3K27me3 at the Nfatc1 transcription start site and thereby activate gene expression. In vitro supplementation of cell-permeable ?KG fully rescued the differentiation defect in PHGDH-null osteoclasts by restoring H3K27Me3 levels and osteoclast-related gene expression. Finally, our findings also hold translational potential, since administration of the PHGDH inhibitor NCT-503 fully prevented bone loss in ovariectomized mice by reducing bone resorption, while bone formation was maintained.Together, this study reveals a RANKL-induced metabolic-epigenetic coupling mechanism in osteoclasts whereby SSP-dependent ?KG synthesis is linked to histone demethylation and Nfatc1 transcription (Fig 1). Moreover, PHGDH inhibition prevents estrogen deficiency-induced bone loss, suggesting that modulation of the SSP might be an appealing strategy to treat osteoporosis.

Bap1 Promotes Osteoclast Function By Metabolic Reprogramming *nidhi rohatgi[1], Wei Zou[2], Steven Teitelbaum[2]. [1]Washington University in St. Louis, United States. [2]Washington University in St. Louis School of Medicine, United States

Treatment of osteoporosis most commonly diminishes osteoclast number which suppresses bone formation thus compromising fracture prevention. Bone formation is not suppressed, however, when bone degradation is reduced by retarding osteoclast functional resorptive capacity, rather than differentiation. We find deletion of deubiquitinase, BRCA1-associated protein 1 (Bap1), in myeloid cells (Bap1?LysM), arrests osteoclast function but not formation. Bap1?LysM osteoclasts fail to organize their cytoskeleton which is essential for bone degradation. Consequently, bone mass increases in the mutant mice. The deubiquitinase activity of Bap1 modifies osteoclast function by metabolic reprogramming. Bap1 deficient osteoclast lineage cells upregulate the cystine transporter, Slc7a11, by enhanced H2Aub occupancy of its promoter. SLC7A11 controls cellular ROS levels and redirects the mitochondrial metabolites away from the TCA cycle, both of which are necessary for osteoclast function. Thus in osteoclasts, Bap1 appears to regulate the epigenetic-metabolic axis and is a potential target to reduce bone degradation while maintaining osteogenesis in osteoporotic patients.

Osteoclast Diversity Highlighted by Transcriptomic and Metabolic Analyses in vitro and in vivo *Julia Halper[1], Maria-Bernadette Madel[1], Valeriia Rezapova[1], Adrien Mahler[1], Konstantin Zaitsev[2], Maria Firulyova[2], Alexandre Gallerand[1], Rafael Argüello[3], Abdelilah Wakkach[1], Didier Pisani[1], Matthieu Rouleau[1], Stoyan Ivanov[1], Claudine Blin-Wakkach[1]. [1]Université Côte d'Azur, Laboratory of Molecular Physio-Medicine- CNRS- UMR7370, France. [2]ITMO University, Computer Technologies Department, Russian Federation. [3]Aix Marseille Univ-CNRS- INSERM, CIML, France

Osteoclasts (OCL) are myeloid cells with various origins, leading to phenotypic diversity. Previously, we showed that monocytes and dendritic cells give rise to two distinct populations of OCLs (MN- and DC-OCLs). Here, we explore OCL heterogeneity at the single cell level and characterize metabolic and functional traits, confirming heterogeneity of mature OCLs.Combination of bulk RNAseq of MN- and DC-OCLs with single-cell RNAseq on mature OCLs from bone marrow (BM-OCLs) revealed metabolic differences. Energetic properties of the subpopulations were defined by SCENITH (Argüello, 2020). Glycolytic and oxidative metabolism, bone resorptive and immune function were analysed in vitro. Metabolic analysis was performed on OCLs extracted ex vivo from Sham and osteoporotic mice (OVX).Transcriptomics identified different OCL clusters and markers, namely CD200 (adj.pVal=1.37*e-05) and CD16/32 (adj.pVal=0.00159) for steady-state and inflammatory OCLs, respectively; in line, MN-OCLs highly expressed CD200 (pVal<0.001) while DC-OCLs were predominantly CD16/32+ (pVal<0.0001) by FACS. Metabolic analysis of CD200+ OCLs revealed an important dependence on both glucose and mitochondrial metabolism, as MN-OCLs. No significant differences were observed in mitochondrial mass, ROS, resorption and antigen presentation capacity between these OCLs. In strong contrast, the CD16/32+ population, as DC-OCLs, displayed a shift from mitochondrial to glycolytic capacity (pVal<0.0001); reduced oxidative metabolism was accompanied by low mitochondrial mass (pVal<0.001) that produced less ROS (pVal<0.001), but increased lactate production through anaerobic glycolysis (pVal<0.01). Their resorption capacity was diminished (pVal<0.001) while antigen presentation was strikingly increased (pVal<0.0001).Importantly, OCLs isolated ex vivo from OVX mice had lower CD200+ but higher CD16/32+ percentage compared to Sham (pVal<0.05). As expected, these ex vivo OVX-OCLs displayed higher glucose dependence (pVal<0.05) than Sham-OCLs, but also a tendency towards increased mitochondrial dependence. Whether energetic demands are divergent for in vitro and ex vivo OCLs is currently under investigation.Here, we reveal the existence of 2 OCL subpopulations that clearly differ in metabolic, resorptive and immune properties, with varying proportions in OVX versus Sham. These findings support the prospect of targeting pathological OCL subsets to improve therapeutic approaches against pathologic bone loss.

Attenuation of NAD+ Metabolism in Osteoclasts Contributes to the Bone Protective Effects of Estrogens *ADRIANA CARVALHO[1], Kimberly Richardson[2], Aaron Warren[2], Maria Jose Almeida[3], Ha-Neui Kim[4, 1], . [2]University of Arkansas for Medical Sciences, United States. [3]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, United States. [4]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States

Mitochondria are a central node of the effects of RANKL on osteoclast formation and bone resorption. NADH oxidation to NAD+ is critical for Complex I activity and the generation of ATP by the electron transport chain. NAD+, in turn, promotes multiple redox reactions and the activity of NAD+-dependent enzymes such as Sirt3. Estrogens attenuate early stimulatory effects of RANKL on Complex I and mitochondria activity of osteoclast precursors. However, how these early effects of estrogens impact osteoclastogenesis remains unclear. Here, we examined the contribution NAD+ metabolism to the anti-osteoclastogenic effects of estrogen. Addition of RANKL to bone marrow-derived macrophages (BMMs) caused an increase in mitochondrial respiration, NAD+ levels, and NAD+/NADH ratio; and 17?-estradiol (E2) prevented all these effects. We next decreased NAD+ levels using FK866, a specific inhibitor of Nampt - the critical enzyme in the NAD salvage pathway. FK866 reduced NAD+ levels, NAD+/NADH ratio, ATP levels, mitochondria respiration, RANKL-induced osteoclast formation, and promoted apoptosis in osteoclast progenitors. While the effects of FK866 were stronger than the ones caused by E2, these findings support the idea that changes in NAD+ mediate the effects of estrogens. To determine the significance of these results to bone in vivo, we next used mice with decreased levels of NAD+ in the macrophage lineage. Specifically, we generated mice lacking one Nampt allele in LysM-cre targeted cells (Nampt?LysM). BMMs from these mice exhibited lower Nampt expression and NAD+ levels. Nampt?LysM mice and Nampt-flox littermate controls were sham-operated or ovariectomized (OVX) at 5 months of age and bone mass was determined 6 weeks later, using DXA BMD and micro-CT. Cortical and trabecular bone of sham-operated Nampt?LysM mice were indistinguishable from control. OVX decreased cortical thickness in the femur and trabecular bone volume in the spine of control mice but these effects were attenuated in the Nampt?LysM mice. Overall these results suggest that an increase in NAD+ levels in osteoclasts contributes to the increase of bone resorption in estrogen deficiency. Along with earlier evidence that the NAD+-dependent mitochondrial deacetylase Sirt3 also contributes to the increase in bone resorption in estrogen deficiency, collectively these findings indicate that inhibition of NAD+ is a functional consequence of suppressive actions of estrogens on osteoclast mitochondria.

Vitamin K-Dependent Carboxylation in Osteoblasts Regulates Osteoclastogenesis through Gas6 *Mathieu Ferron[1], Diep Ngoc Thi Pham[1], Monica Pata[1], B. Ashok Reddy[1], Julie Lacombe[1], Amélie Germain[1], Céline Schott[1]. [1]Institut de recherches cliniques de Montreal, Canada

Interventional and observational studies in humans suggest that vitamin K (VK) plays a role in the regulation of bone remodeling. In cells, VK functions as a co-factor for the ?-carboxylase (GGCX), an enzyme responsible for the conversion of glutamic acid residues (Glu) into ?-carboxyglutamic acid (Gla) residues in specific secreted proteins. This post-translational modification is notably present in osteocalcin, the most abundant non-collagenous protein in bone extracellular matrix (ECM) and an osteoblast-derived hormone affecting glucose metabolism. However, gain- and loss-of-function mouse models of osteocalcin have shown that this protein does not affect bone remodeling and is not required for normal bone ECM mineralization. Therefore, the mechanism and the Gla protein(s) through which VK influences bone density and/or quality remain to be characterized. To address this question, we generated mice lacking ?-carboxylation specifically in osteoblasts by breeding mice harboring a Ggcx floxed allele with the hOC-Cre transgenic line, which express Cre recombinase in osteoblasts. Histological analysis revealed that these Ggcxff;hOC-Cre mice have increased bone mass at 6 months of age. This phenotype appears to be caused by a decrease in the number of multinucleated bone resorbing osteoclasts. In co-cultures experiments, GGCX-deficient osteoblasts were less effective than control osteoblasts at supporting the generation of large osteoclasts. In contrast, osteocalcin-deficient osteoblasts did not display this phenotype, suggesting the involvement of another osteoblast derived Gla protein. Among all known Gla proteins, we found that, beside osteocalcin, Gas6 was the most highly expressed in osteoblasts. In cell culture assays, recombinant ?-carboxylated Gas6 dose-dependently increases the size of osteoclasts and the number of nuclei per osteoclasts in presence of RANKL and M-CSF. Genes involved in osteoclast differentiation were not affected by recombinant Gas6, suggesting that Gas6 might be involved in pre-osteoclast fusion. The Gas6 receptor tyrosine kinases, MerTK and AXL, were expressed in pre-osteoclasts and two different AXL inhibitors completely block osteoclast generation in co-culture assays, indicating that Gas6 signaling through these receptors is required to support pre-osteoclast fusion. This work identifies Gas6 as a novel osteoblast derived Gla protein regulating osteoclast maturation and potentially mediating the effect of VK on bone turnover.

Optimizing spatial transcriptomics in mouse bone from the single gene to the whole transcriptome identifies regional changes in response to applied load *Samia Saleem[1], Erica Scheller[1], ALEC BEEVE[2], Katherine Minielly[1], Lisa Lawson[3], John Shuster[1], David DeBruin[4], Michelle Brennan[5], Matthew Silva[6]. [1]Washington University, United States. [2], . [3]Washington University in St. Louis, . [4]St. Louis University , United States. [5]Saint Louis University , United States. [6]Washington University in St. Louis School of Medicine, United States

Spatial transcriptomics allows for resolution of gene expression in the spatial dimension from the single-gene to the whole transcriptome. However, methods are not well optimized for bone, which limits current applications. To overcome this, we optimized protocols for single gene RNAscope prior to adaptation for whole transcriptome analysis (WTA) using the NanoString GeoMx platform. This workflow was used to analyze gene expression in the periosteum and cortical bone after biomechanical loading of the mouse tibia. Specifically, 5-month old C57Bl/6 mice were loaded unilaterally to -2200 µ? for 5-days and sacrificed 4-hours after the final loading bout. Non-loaded and loaded tibias were harvested and transverse paraffin sections from the mid-diaphysis were prepared for analysis. Spatial capture tools were used to subdivide each section into regions of maximum tensile and compressive strain, resulting in four areas of interest (AOIs) per section (max compressive-bone; max compressive-periosteum; max tensile-bone; max tensile-periosteum). Periosteal and cortical bone AOIs expressed gene profiles in accordance with tissue type, providing evidence of successful AOI selection (ex. Postn, Bglap, Sparc, and Aspn enriched in periosteum; Mepe, Dmp1, and Dkk1 enriched in bone). The resulting spatial transcriptomic datasets were also validated against prior bulk tissue RNAseq. This identified 128 overlapping DEGs between gene sets ($p<0.05$, $Log2FC>|0.5|$) including known responders such as Bglap, Col1a1, Gja1, and Phospho1. Regression analysis of overlapping genes revealed relatively high concordance in fold change between techniques ($r2=0.556$, $p<0.001$). AOI-based subanalysis of the spatial data in bone vs periosteum identified 224 vs 809 significant DEGs with loading, respectively. Gene ontology analysis revealed an upregulation of genes associated with collagen fibril organization and mineralization in bone, while key genes and pathways associated with collagen biosynthesis, vesicle transport, osteoblast differentiation, and angiogenesis were more prominent in the periosteum. Further characterization based on FEA-determined stress maps identified a spectrum of loading-induced gene changes with maximal upregulation of osteoanabolic genes and pathways at sites of maximum compression. Overall, this

novel workflow substantially expands our capabilities for spatial WTA in bone tissues while clarifying the relationship between applied stress and regional skeletal adaptation.

Obesity impairs revascularization and bone healing in a mouse model of ischemic osteonecrosis *Zhuo Deng[1], Maria Aguirre[1], Harry Kim[1], Yinshi Ren[1]. [1]Scottish Rite Hospital, United States

Osteonecrosis (ON) of the femoral head (ONFH) is the major form of ON and affects patients in their early 30s. With the arising concerns of obesity worldwide, it is found that obesity is highly correlated to the increased incidences of ONFH. However, it is unclear if obesity directly affects the progression and healing of ON. The purpose of this study is to investigate the effects of obesity on bone healing and revascularization in an established mouse model of ischemic ON.A total of 27 mice are randomly assigned into three groups at the young adult age of 3 months: Group 1) Control mice fed with normal diet (ND); Group 2) Obese (Ob) mice fed with high-fat-diet (HFD) containing 60% kcal and Group 3) Weight Loss (WL) mice was initially fed with HFD and then switched to normal diet to reduce body fat. ON was surgically induced on the right distal femoral epiphysis and the left side serves as Sham control. All mice are sacrificed at 4 weeks after the surgery. Micro-CT, IHC and histomorphometry were used to measure bone remodeling and vascularization. Endothelial cell (HUVEC) tube formation assay and qPCR were performed to investigate the effects of LDL on endothelial cells.At 4 weeks after surgery, all mice in the control group had a complete revascularization of ON bone, while the Ob group had a significant reduction in re-vascularized marrow space ($p<0.05$) and endomucin positive vessel areas (50% reduction, $p<0.05$) (Figure 1). Histomorphometry on HE and TRAP staining showed significantly reduced osteoblasts($p<0.01$) and osteoclasts($p<0.01$) in Ob mice compared to control. WL animals show rescued bone remodeling and revascularization. Serum LDL was significantly increased in the Ob group compared to both control and WL groups. Addition of 100 μg/ml oxLDL markedly reduced endothelial cell branching in the tube formation assay with reduced total length ($p<0.05$), number of nodes ($p<0.01$) and branches ($p<0.05$), indicating decreased vascularization. Notch signaling is known to stimulate angiogenesis. Downstream gene analysis revealed that oxLDL decreased Notch4 and DLL1 expression ($p<0.05$), and activation of Notch signaling in HUVEC cells rescued the tube formation defect induced by oxLDL.Our study is the first to investigate the role of obesity in osteonecrosis bone healing. We identified a potential LDL-Notch signaling cascade that blocked angiogenesis in ON, providing novel thoughts for future treatment of ON.

CircFam190a: a positive regulator of osteoclast differentiation via acting as a scaffold for HSP90?/AKT1 *Kun Chen[1], Mingyou Xu[1], Zhi Li[1], Xingshi Yuan[1], Xifu Shang[1]. [1]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, China

The identification of key regulator factors that control osteoclasteogenesis is of vital importance. Accumulating evidence indicates that circular RNAs (circRNAs) are discrete functional entities. However, the complexities of circRNAs expressions as well as the extent of their regulatory functions during osteoclastogenesis are yet to be revealed.Using circular RNA sequencing, we identified 1013 circular RNAs during osteoclastogenesis. Among these, circFam190a, generated from the Fam90a gene, caught our attention [Attachment Figure1]. In mice with ovariectomy surgery, a condition characterized by hyperactive osteoclasts, circFam190a expression was significantly elevated. Similarly, the expression level of circFAM190A in post-menopausal osteoporosis patients was significantly up-regulated. In vitro culture studies demonstrated a significant increase in circFam190a expression during Rankl-induced osteoclastogenesis. These findings indicate a close relationship between circFam190a and osteoclasts, motivating us to further investigate.For in vitro function studies, circFam190a was found to enhance osteoclast formation and function, while its knockdown inhibited osteoclast formation. In vivo, overexpression of cirFam190a induced significant bone loss, whereas knocking down cirFam190a prevented pathological bone loss in an ovariectomized (OVX) mice osteoporosis model [Attachment Figure2]. Mechanistically, our data suggest that cirFam90a enhances the combination of AKT1 and HSP90?, promoting AKT1 stability. Moreover, the use of the AKT signaling inhibitor MK2206 successfully rescued circFam190a's osteoclast hyperactive phenotype in mice.Altogether, our findings highlight that circFam190a, a circular RNA that binds directly to HSP90? and AKT1, is an important positive regulator of osteoclasteogenesis [Attachment Figure3]. Targeting circFam190a could efficiently ameliorate OVX-induced osteoporosis. These findings contribute to our better understanding of the mysterious of circular RNA and bone metabolism, and provide potential therapeutic targets for treating pathological bone loss.

Altered Mitochondrial Protein Acetylation in Osteoclasts May Lead to Skeletal Disintegration in Young Adult Male Mice Exposed to Ionizing Radiation *Gareeballah Balla[1], Kimberly Richardson[2], Qiang Fu[3], Nukhet Aykinburns[2], Ha-Neui Kim[4]. [1]University of Arkansas for Medical Sciences , United States. [2]University of Arkansas for Medical Sciences, United States. [3]Institute of Nuclear Medicine, United States. [4]Univ. Arkansas for Medical Sciences, Central Arkansas VA Healthcare System, United States

The damaging effects of ionizing radiation (IR) on bone mass have been well documented in mice and humans. Biomarker studies conducted in patients indicated that increased bone resorption is a predominant source of bone loss. However, the mechanisms leading to the acute activation of osteoclasts that follows exposure to IR remain unknown. SIRT3, the primary mitochondrial deacetylase, plays a crucial role in maintaining mitochondrial quality control during stressful conditions, such as aging, and oxidative stress, most likely by promoting deacetylation of its target proteins. Here, we examined the contribution of osteoclast mitochondria to the adverse effects of low-dose IR. Cultured bone marrow-derived macrophages were exposed to ?-radiation (2 or 4 Gy), which resulted in an increase in osteoclast size and activity; and this was associated with an increase in mitochondrial respiration and mRNA levels of SIRT3. To determine the significance of these findings to bone in vivo, we next subjected 6-month-old male SIRT3 KO mice and WT littermates to 4 Gy total body irradiation with fractionated exposures for 3 months. Low-dose IR exposures caused a dramatic decrease in trabecular, but not cortical bone mass, in both the femur and the spine of WT mice, as determined by DXA and micro-CT. Notably, the IR-induced bone loss was greatly attenuated in SIRT3 KO mice. Consistent with the high trabecular bone mass, the serum marker of bone resorption, CTX was dramatically lower in irradiated SIRT3 KO mice than in irradiated WT littermate mice. Our proteomic analysis of SIRT3-deficient osteoclasts revealed a dramatic increase in acetylation of ATPIF1 and SOD2, which are essential for mitophagy and mitochondrial ROS, respectively. Knockdown of either ATPIF1 or SOD2 in osteoclast progenitors impaired resorptive activity and suppressed mitophagy, suggesting an important role in osteoclast function and mitochondrial quality control. In addition, Mito-TEMPO, a mitochondrial superoxide scavenger, dose-dependently decreased RANKL-induced osteoclast formation in ex vivo cultures from mice exposed to radiation. These results demonstrate that SIRT3 plays an essential role in excessive bone resorption that occurs with IR exposure by promoting deacetylation in osteoclast mitochondria. Understanding the mechanisms of mitochondrial quality control and protein acetylation in osteoclasts could pave the way for developing novel strategies to counteract radiation-induced bone loss.

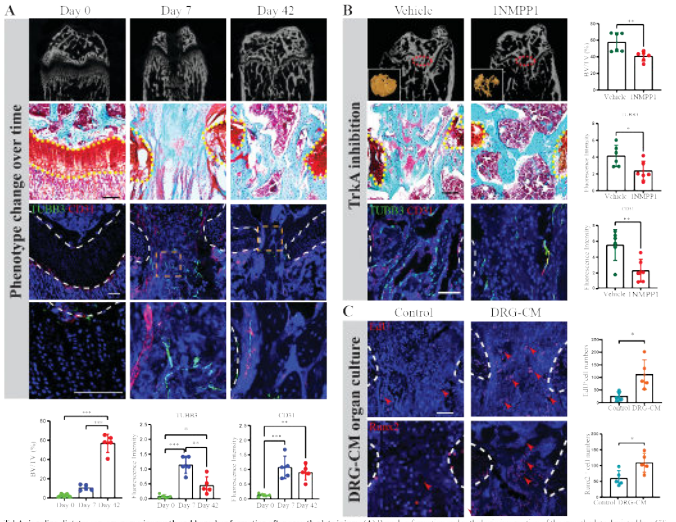
TrkA signaling dictates sensory nerve ingrowth and bony bar formation after growth plate injury *Xin Xing[1], Zhao Li[1], Sowmya Ramesh[1], Austin Chen[1], Mary Archer[1], Ziyi Wang[1], Qizhi Qin[1], Neelima Thottappillil[1], JiHye Yea[1], Mingxin Xu[1], Manyu Zhu[1], Thomas Clemens[2], Aaron James[1]. [1]Johns Hopkins University, United States. [2]University of Maryland, Baltimore, United States

Purpose: Injuries to the growth plate often lead to the formation of a bony bar, causing bone growth limitations, limb length discrepancies, and angular deformities in children. However, the mechanisms underlying this undesirable bony repair remain poorly understood. Recent studies have implicated TrkA+ sensory nerves in the regulation of skeletal cells and tissues, suggesting their potential role in the tissue response to growth plate injury. Methods: A drill hole injury was created in the distal epiphysis of 4-week-old male C57BL/6 and nerve growth factor (NGF)-eGFP reporter mice to model bony bar formation in growth plate injury. ?CT analysis, histology, TUBB3, and CD31 immunofluorescent staining were employed to assess bony bar formation, innervation, and angiogenesis at 1 and 6 weeks post-injury. Temporary inhibition of TrkA signaling was achieved in 4-week-old male TrkAF592A mice with 1NMPP1 treatment, and its effects were evaluated by ?CT analysis and immunofluorescent staining (TUBB3, CD31). Conditioned medium from dorsal root ganglia (DRG) was isolated for ex vivo organ culture of the injured growth plate, and EdU incorporation assay and Runx2 immunostaining were performed at 1 week post-culture. Results: ?CT analysis and histological staining revealed longitudinal disruption of the growth plate through the drill hole injury, resulting in a progressive increase in bone tissue formation at the injury site from day 7 to day 42 (Fig A). NGF expression, nerves, and blood vessels were found to be absent in the uninjured growth plate (day 0). Exuberant sprouting of nerves and vasculature into the growth plate injury site was identified at 1 week post-injury, which persisted above baseline at 6 weeks post-injury (Fig A). Inhibition of TrkA signaling significantly reduced bony bar formation at 6 weeks (-17% BV/TV) in the injured growth plate, along with decreased innervation (1.75-fold), and vascularization (2.42-fold) at 1 week post-injury. Ex vivo organ culture experiments demonstrated that conditioned medium from DRG-derived sensory neurons resulted in a 1.82-fold increase in EdU-positive cells and a 4.48-fold increase in Runx2-positive cells in the injured growth plate (Fig C). Conclusions: To our knowledge, this study represents the first investigation into the role of TrkA+ sensory nerves in the growth plate's response to injury. The findings contribute to our understanding of pathologic endochondral ossification and may facilitate the development of future preventative biological treatments.



TrkA signaling dictates sensory nerve ingrowth and bony bar formation after growth plate injury. (A) Bony bar formation and pathologic innervation of the growth plate depicted by µCT images, Safranin O/Fast green staining, TUBB3, and CD31 immunofluorescent (IF) staining at day 0, 7, and 42. Quantitative analysis includes BV/TV measured by µCT and semiquantitative analysis of TUBB3 and CD31 expression. N=5 (B) Inhibition of TrkA+ sensory nerves reduce bony bridge formation as observed in µCT images, Safranin O/Fast green staining of the injured growth plate in TrkA^{F592A} mice treated with 1NMPP1 or vehicle control at day 42 after injury. TUBB3 and CD31 IF staining was performed at day 7 after injury. Quantitative analysis includes BV/TV and semiquantitative analysis of TUBB3 and CD31 expression. N=4-6 (C) Dorsal root ganglion-derived conditioned medium (DRG-CM) modulates the metabolism of in vivo cultured injured growth plate, as indicated by EdU incorporation and Runx2 IF staining. N=5. Accelerated Physical Decline after Fracture in Older Men - the Prospective STRAMBO Study *Pawel Szulc[1], Joshua Lewis[2], Roland Chapurlat[3]. [1]INSERM UMR 1033, University of Lyon, Hopital E. Herriot, Pavillon F, France. [2]Edith Cowan University, Australia. [3]INSERM UMR 1033, France

Prospective data on the loss of muscle strength and physical function after a fracture are scarce. Few studies have compared fracture-related loss of muscle strength and physical function with normal ageing-related decline. Our aim was to compare the loss of muscle strength and physical function after an incident fragility fracture to normal ageing-related decline in a prospectively followed cohort of older men.In 823 men aged 60-87 years, grip strength measurements and clinical tests (chair stands, balance) were performed every 4 years for 12 years. Incident vertebral fractures were assessed every 4 years on the lateral spine DXA scans. Self-reported low trauma non-vertebral fractures were confirmed by health professional. In 155 men with incident fracture, we compared the status on the first visit after fracture vs. that on the last visit before the fracture. In men without fracture (controls), we compared the status on the first follow-up (4 years) vs. baseline.After adjustment for confounders, the loss of grip strength was 41% higher (0.28SD, p<0.01) in men with incident fracture vs. controls. Men with fracture were more likely to become unable to stand for 10s with closed eyes (OR=4.80, 95%CI: 1.49-15.42, p<0.01) or to have an incident deterioration on the chair stand test (OR=2.45, 95%CI: 1.49-4.05, p<0.001) vs. controls. The risk of decline on the dynamic balance tests (tandem walk) was higher in men with fracture vs. controls: forwards (OR=2.04, 95%CI: 1.22-3.42, p<0.01), backwards (OR=2.25, 95%CI: 1.31-3.85, p<0.005).The decline after fracture was also greater in anatomical regions remote from the fracture site. Grip strength decreased more (34%, 0.24SD, p<0.05) in men who had no upper limb fracture vs. controls. The risk of decline in the tests of the lower limbs was higher in men who had no lower limb fracture, e.g., chair stands (OR=2.73, p<0.001) or tandem walk backwards (OR= 2.08, p<0.05). Men with incident vertebral fracture had 38% higher loss of grip strength (0.29SD, p<0.05) as well as higher risk of decline on the chair stands (OR=2.42, p<0.01) and on the backward tandem walk (OR=2.53, p<0.01).In older men followed prospectively, fractures were associated with greater loss of muscle strength and higher risk of physical function decline vs. normal ageing. This rapid decline was general and not limited to the fracture site. Thus, rehabilitation programs to prevent this post-fracture functional decline are urgently needed.

AI-based Osteoporosis Screening with Chest Radiographs: Correlation Analysis between AI-Score and T-Scores *Mingyu Kim[1], Sung Jin Bae[2], Jung-Min Koh[2], Gaeun Lee[1], Namkug Kim[2], Miso Jang[2]. [1]Promedius Inc., Republic of Korea. [2]Asan Medical Center, Republic of Korea

Osteoporosis is a major public health challenge with significant implications for global health. Given the heightened treatment uptake and compliance rates resulting from raising awareness of osteoporosis, osteoporosis screening emerges as the most effective approach. In this study, we investigated the correlation between T-scores and an AI-score outputs from an AI model for osteoporosis screening with chest radiographs. The AI model was trained using deep learning by matching chest radiographs with DXA-based osteoporosis diagnosis.

The training data were obtained from the Health Screening and Promotion Center in Asan Medical Center, Korea (IRB No 2019-1226). The model achieved AUC of 0.91 and 0.88 for internal and external test set, respectively (Jang et al., J. Bone Miner Res. 2022, 37, 369-377). Using the test set, we evaluated the Spearman correlation coefficient between the AI-score and the T-scores (Femoral neck and Lumbar spine). Our findings revealed correlation coefficients of -0.594 and -0.741 for T-scores from the Femoral neck and Lumbar spine, respectively. AI-score is continuous values between 0 and 1. Negative correlation is due to inverse relation between the T-score and the AI score. Here, only correctly classified by AI model to either of non-osteoporosis or osteoporosis data were used for correlation analysis. Notably, the T-score from the Lumbar spine demonstrated a 24.7% higher correlation than that from the Femoral neck. This implies that the AI model easily learns lumbar spine structure in chest radiograph where femoral neck does not cover. Despite the promising results of our study, several limitations should be acknowledged. The AI model and evaluated data were limited to a specific medical center in Korea, which may introduce variations in correlation tendencies with other populations. In addition, the AI-score distribution in the figure is highly skewed towards 0s and 1s indicating that the need of T-score calibration by training AI model to estimate T-score directly. In conclusion, our study highlights the potential of AI-based screening models to predict T-scores across a continuous range from normal to osteoporosis. This correlation function can be used for monitoring individual patients for appropriate treatment as well as enabling early-stage detection even in the absence of discernible symptoms. Future research should consider broader population samples and further refinement of the AI model to enhance its clinical utility.

Bone-Targeted Pre-Conditioning Prevents Bone and Muscle Injury in Australian Army Recruit Training: The PREFIT Study *Belinda Beck[1], Graeme Jones[2], Stephan Rudzki[3], Mark Barclay[4], Paul Scuffham[1]. [1]Griffith University, Australia. [2]University of Tasmania, Australia. [3]Canberra Sports Medicine, Australia. [4]Kapooka Health Centre, Australia

PurposeBone will adapt to progressive mechanical loading but overly rapid training increments such as occurs in Army recruit training (ART) causes bone stress injuries. We hypothesized that bone-targeted training prior to ART would reduce injuries during ART. Our aims were to determine 1. if bone-targeted preconditioning could reduce musculoskeletal injuries and costs during ART at the Army Recruit Training Centre (Kapooka, NSW, Australia), and 2. factors related to incidence of musculoskeletal injury during ART.MethodsPREFIT was a prospective, voluntary controlled trial of 45mins 5d/wk bone-targeted preconditioning offered to candidates to the Australian Army scheduled to enlist within 5 months. At baseline, enlistment and march out we collected biometrics, health history, medications, heel BUA (QUS, Achilles, GE); muscle strength and power (TTM Muscle Meter; GymAware, respectively); functional reach; #push-ups, #sit-ups, shuttle run performance, vitamin D; prior physical activity (BPAQ); dietary calcium (AusCal) and prior injuries. Preconditioning adherence and musculoskeletal injuries sustained during 12-week ART were monitored. We compared rates and costs of musculoskeletal injury in recruits who did and did not undertake PREFIT training and examined predictors of injury.ResultsWe enrolled 91 candidates into PREFIT training of which 37 entered recruit training (54 decided not to enlist). Only 25 completed sufficient PREFIT training prior to enlisting to qualify as 'pre-trained'. 349 platoon-mates consented to be controls. Mean age was 22+/-5.4yrs. 19% of the PREFIT-group versus 61.2% of non-PREFIT trained recruits sustained an injury. 10.7% of the PREFIT group sustained a musculoskeletal injury versus 37.7 % of the non-PREFIT group. There was insufficient power to examine bone injuries, but for every 1-unit increase in BUA or #push-ups, the odds of a bone injury was 0.97 and 0.96 times lower, respectively (p=0.033; p=0.041). Variables associated with a lower extremity injury and bone injury included height, BUA, leg power, #push-ups, #sit-ups, shuttle run, smoking, and previous medication. Total medical cost was $1308/PREFIT recruit versus $2,241/non-PREFIT recruit, i.e. almost double. No PREFIT recruit was discharged due to injury versus 4 non-PREFIT.ConclusionsA bone-targeted preconditioning program was a simple strategy to reduce musculoskeletal injury and cost to the Army for recruit training. Taller, stronger, fitter recruits are less at risk.

Improved Real-World Prediction of Hip Fracture Using CT-Based Measurements of Bone, Muscle, and Soft Tissue in Women and Men *Tony Keaveny[1], David Lee[2], Mary Bouxsein[3], Eric Orwoll[4], Sundeep Khosla[5], Michael McClung[6], Ethel Siris[7], David Kopperdahl[2], Annette Adams[8]. [1]University of California, Berkeley, United States. [2]O.N. Diagnostics, United States. [3]Beth Israel Deaconess Medical Center, Harvard Medical School, United States. [4]Oregon Health & Science University, United States. [5]Mayo Clinic College of Medicine, United States. [6]Oregon Osteoporosis Center, . [7]Columbia University College of Physicians and Surgeons, United States. [8]Kaiser Permanente Southern California, United States

Introduction: Reflecting the biomechanics of hip fracture, we hypothesized that combined measurements related to bone strength, postural instability, body size, and soft tissue cushioning can improve clinical prediction of hip fracture compared to standard of care. Specifically, using measurements taken only from a patient's hip-containing CT scan, we developed a method ("Biomechanical CT Plus", BCT+) for identifying patients at high risk of hip fracture and then compared fracture prediction for BCT+ versus BMD and FRAX.Methods: Our case-cohort sample of 11,461 patients was drawn from 271,389 patients age >= 65 who had a hip-containing CT scan (start of observation) during clinical care. Cases were all those with a hip fracture after the CT scan; an equal number of sub-cohort patients was randomly selected (sex- and facility-matched). Using the CT scan, over 50 measurements in the hip region were taken of: 1) strength (by finite element analysis), density (volumetric and areal, including DXA-equivalent hip BMD T-score), and geometry of the bone; 2) muscle morphology; 3) body composition; and 4) soft tissue thickness. Hip fracture status and risk factors for FRAX were taken from electronic records. The BCT+ model was formulated by sex-specific logistic regression (nine variables were chosen) for patients from half the facilities (outcome = hip fracture status at five years). For the other facilities, fracture prediction for the BCT+ model was compared against predictions from hip BMD T-score (lower of femoral neck/total hip) and FRAX 10-year probability of hip fracture (with femoral neck BMD T-score).Results: Overall, there were 4,959 hip fractures at five years. For BCT+, risk of hip fracture increased with higher values of age, bone volume, intra-muscular % fat content, and body-composition total area (women only) and with lower values of femoral strength, ratio of trabecular-to-cortical volumetric BMD, muscle size (area), body-composition % fat content (women only), and posterior fat thickness (women only). Area under the ROC curve was significantly higher (p<0.0001) for BCT+ (0.79, 95% CI: 0.77-0.80) than for BMD (0.72, 0.71-0.74) and FRAX (0.73, 0.72-0.75); these trends persisted by sex (women: 0.79/0.72/0.74, respectively; men: 0.78/0.72/0.73). For all specificity values, sensitivity was highest for BCT+ (Figure).Conclusions: In a real-world clinical setting, prediction of hip fracture was improved by BCT+ compared to current standard of care.

Fracture following Kidney and Simultaneous Pancreas-Kidney Transplantation is predicted by DXA-derived Bone Mineral Density and Advanced Hip Analysis *Tahira Scott[1], Jasna Aleksova[2], Ryan Gately[1], Harpreet Kaur[3], Carmel Hawley[1], Mirna Vucak-Dzumhur[3], Mina Khair[1], James Elhindi[4], Grahame Elder[5]. [1]Faculty of Medicine, The University of Queensland, Princess Alexandra Hospital, Australia. [2]School of Clinical Sciences, Monash University, Hudson Institute of Medical Research, Australia. [3]Westmead Hospital, Western Sydney Local Health District, Australia. [4]Westmead Hospital, University of Sydney, Australia. [5]Westmead Hospital, Univeristy of Notre Dame,University of Sydney, Garvan Institute of Medical Research, Australia

Patients with kidney failure have accelerated trabecular and cortical deterioration and elevated fracture risk that remains high following kidney transplantation. Contributing factors include chronic kidney disease-mineral and bone disorder and immunosuppressive treatment. BMD is less predictive of fracture in patients with kidney failure. This study aimed to determine if the DXA-derived trabecular bone score (TBS) and advanced hip analysis (AHA) improved BMD-based fracture prediction.Patients from two Australian transplant centres receiving kidney or simultaneous pancreas-kidney (SPK) transplants were included. Baseline information included demographics, medications and lab. data. A DXA scan was performed as soon as practical post-transplant to provide BMD, TBS and AHA parameters; femoral neck, calcar and shaft cortical thickness (CTh), and the femoral neck buckling ratio (BR), an indicator of structural instability defined as radius/CTh. Patients received treatment to reduce post-transplant BMD loss based on a risk algorithm(1). Parameters with skewed distributions were log transformed, and hazard ratios were determined using Kaplan Meier and Cox proportional hazard models with multivariable adjustment.Of 357 kidney and SPK transplant recipients, 289 (83%) received a kidney-only transplant. Mean age was 48+/-13 years, 62% were male, 20% had type 1 diabetes mellitus (T1DM) and median dialysis vintage was 29 months (IQR: 12, 60). There were 81 incident fractures, with median time to fracture or censoring 4.4 years (2.5, 5.5). Incident fracture was predicted by T1DM (p<0.001), former smoking (p=0.017), lower 25OHD (p=0.045), axial BMD (p<0.01), CTh (all sites p<=.01) and the BR (p=0.004; HR 1.83 (1.34, 2.49) for each log-unit increase), but not by the TBS. After multivariate adjustment, T1DM, 25OHD, smoking, prevalent fracture and hip BMD remained significant predictors. Using the BMD-based risk algorithm, inclusion of an interaction parameter for BR above or below the median improved the model fit (HR 2.36 (0.96, 5.80); p=0.06). Fracture risk increased from low-risk and low BR, to low-risk high BR, and high risk (Fig. 1).DXA-derived BMD, AHA cortical parameters and the BR predict incident fracture in kidney and SPK transplant recipients but TBS does not. AHA by DXA is readily available and may improve fracture risk assessment, particularly in kidney and SPK transplant patients whose BMD suggests fracture risk is low.1. Elder G. Transplantation 2023

Exploring a Whole New World of Bone: Osteomorphs and Insights Utilizing an Ovariectomized Cynomolgus Monkey Model *Alana Stahl[1], Alexandra Olsen[2], Andrew Sawatsky[1], Brent Edwards[3], Roman Krawetz[4]. [1]McCaig Institute for Bone and Joint Health, Faculty of Kinesiology, Canada. [2]McCaig Institute for Bone and Joint Health, Department of Biomedical Engineering, Canada. [3]McCaig Institute for Bone and Joint Health, Faculty of Kinesiology, Department of Biomedical Engineering, Canada. [4]McCaig Institute for Bone and Joint Health, Department of Biomedical Engineering, Department of Cell Biology and Anatomy, Cumming School of Medicine, University of Calgary, Canada

Antiresorptive treatments for osteoporosis include denosumab (DMAb) and alendronate (ALN), which inhibit the function and survival of osteoclasts and the action of osteoclasts, respectively. Osteomorphs are osteoclasts that have been recycled via fission into smaller, highly mobile units. These osteomorphs can then fuse together to form new osteoclasts when needed. Though their mechanics remain elusive, osteomorphs play a role in bone resorption and therefore are likely active players in osteoporosis. The purpose of this study was to determine the effects ALN and DMAb have on osteoclast and osteomorph survival in a non-human primate model of osteoporosis.Adult cynomolgus monkeys were ovariectomized and randomly assigned to 12 monthly injections of s.c. vehicle (VEH; n = 6), s.c. DMAb (25 mg/kg, n = 6), or i.v. ALN(50 ?g/kg, n = 6). Other groups received 6 months of VEH followed by 6 months of DMAb (VEH-DMAb; n = 6) or 6 months of ALN followed by 6 months of DMAb (ALN-DMAb; n = 6. After sacrifice, the humeri were fixed, decalcified, then paraffin embedded. Sections were stained with TRAP and CD115 and the slides were fluorescently imaged. Tissue cytometry (TissueQuest) was performed on the images to detect and quantify cells expressing none, either or both marker. The number of cells/mm2 for all cell populations of interest (osteoclasts and osteomorphs) was analyzed.Cells expressing TRAP alone (osteoclasts) and those expressing both CD115 and TRAP (osteomorphs) were detected within all treatment groups (Fig. 1). Animals receiving treatment (ALN or DMAb) had significantly lower TRAP cell counts than the VEH group. There were no differences in the number of osteomorphs (CD115 and TRAP double positive cells) between any treatment groups.DMAB inhibits RANK ligand (RANKL), which in turn prevents osteoclasts from resorbing bone. It has been suggested that blocking RANKL inhibits the fusion of osteomorphs into osteoclasts, causing the accumulation of osteomorphs, which has never been previously observed in a non-human primate. Interestingly, while we observed a decrease of osteoclasts with treatment (as expected), osteomorph numbers were not impacted by ALN or DMAb. This resulted in an increase in the relative abundance of osteomorphs vs. osteoclasts in animals, particularly in the DMAb treatment group. Further research is required to understand the role of osteomorphs and if these cells play a role in rebound resorption after DMAb cessation.

Delineating the role of Fshr in Bone Remodeling Using Novel Genetic Mouse Models *Mingxin Sun[1], Hongqian Chen[1], Li Xing[1], Libin Chen[1], Dr. Clifford ROsen[2], Mone Zaidi[3], Peng Liu[1]. [1]Laboratory of Bone and Adipose Biology, Shanxi Medical University, Taiyuan, China, China. [2]Maine Medical Center, United States. [3]Mount Sinai Medical Center, United States

FSH, secreted by anterior pituitary gonadotropic cells, has been traditionally held as a hormone that solely regulates reproduction through its G-protein-coupled receptor, the FSHR. However, there is increasing evidence for roles of FSH in the regulation of bone and adipose tissue remodeling, vascular function, lipid homeostasis, and cognition [e.g. Cell, 2006 PMID: 16630814; Nature, 2017, PMID: 28538730; Nature, 2022; PMID: 35236988]. Nevertheless, the extragonadal expression and function of the FSHR has been debated. To address this challenge and to precisely localize Fshr expression, we created a Fshr promoter-driven ZsGreen reporter mouse line. We found strong Fshr expression in the osteoclast, osteoblast, bone lining cells, and osteocytes. To understand the role of the FSHR in bone formation, we further developed floxed Fshr cKO mice, which we bred with a 10 kb Dmp1-CreERT2 line. We used micro-CT and NMR to sequentially assess bone and adipose tissues in mice on normal chow or high fat diet (HFD). Significant increases in bone mass were noted in both male and female tamoxifen (TMX)-induced Fshr cKO mice, on both normal chow and HFD, compared with the respective uninduced controls. In addition, we found an increase of markers of bone turnover, including osteocalcin, PINP and TRACP5b (ELISA). Histomorphometric parameters of bone resorption were also elevated, indicating that both bone formation and bone resorption were increased in Fshr cKO mice. Surprisingly, on quantitative NMR and micro-CT, we also noted a marked reduction of visceral adipose tissue in male Fshr cKO mice, but not in females fed on normal chow. There were no differences in subcutaneous adipose tissue in both sexes. However, when fed on HFD, both males and females showed a significant reduction in visceral and subcutaneous adipose tissue. We also studied the ovariectomized and aged Fshr cKO mice to find increased bone mass in the Fshr cKO, while trabecular bone was lost in the respective uninduced controls. To study the mechanism underpinning the bone conservation in Fshr cKO mice, we performed RNA-seq on femur-derived RNA from Fshr cKO and uninduced control mice on normal chow and HFD. We found that sclerostin (Sost) expression was downregulated by 10-fold in Fshr cKO mice fed on HFD compared with uninduced controls. However, there was an unexplained increase in Sost expression by 2-fold in the Fshr cKO mice fed on normal chow. In addition, we found a 5-fold increase in Lcn2 expression. The results collectively demonstrate that the selective deletion of the Fshr in osteocytes in adult, aging and ovariectomized mice, yields a remarkably robust bone conservation, while also resulting in a lean phenotype, via a yet uncharacterized mechanism.Our results suggest that removing the inhibition of bone formation by the Fsh-Fshr complex could have therapeutic implications.

Denosumab inhibits the transition from erosion to formation in cortical remodeling of osteoporotic patients, similar to bisphosphonates *Xenia Borggaard[1], Jean-Paul Roux[2], Jean-Marie Delaisse[3], Shuang Huang[4], Pascale Chavassieux[5], Christina Andreasen[6], Thomas Andersen[7]. [1]Odense University Hospital, Denmark. [2]INSERM, UMR 1033, Universite de Lyon, France. [3]Odense University Hospital, KI, University of Southern Denmark, Denmark. [4]Amgen Inc, United States. [5]INSERM UMR1033, Universite De Lyon, France. [6]ODENSE UNIVERSITY HOSPITAL, Denmark. [7]University of Southern Denmark, Denmark

Osteoporosis is caused by an imbalance between bone resorption and bone formation, causing low bone mass and fragile bones. Denosumab inhibits maturation of osteoclasts thereby increasing BMD and reducing osteoporotic fractures. The increased BMD is presumably caused by closure of remodeling spaces and secondary mineralization. However, many questions concerning its effect on cortical bone remain unanswered. In this study, we use a series of new histomorphometric endpoints to investigate the intracortical and periosteal effect of denosumab treatment within bone biopsies collected during the FREEDOM study.The study included 164 iliac crest bone biopsies from osteoporotic patients treated with denosumab or placebo for 2-3 years. Goldner Trichrome stained sections cut from the biopsies were scanned under polarized light using Olympus VS200 microscope. Cortical area and area/size of intracortical pores were semi-automatically measured using VS200 Desktop 3.2.1 & DNN TruAI software. Each intracortical pore was manually classified according to their remodeling stage (eroded, eroded-formative, formative, or quiescent), and the percentage of eroded and formative periosteal surfaces were measured.In total, 8411 intracortical pores were measured and classified. The analysis revealed a significant reduction in mean pore diameter ($p = 0.002$), but no reduction in mean pore area ($p = 0.15$) or decrease in cortical porosity ($p = 0.077$) in patients treated with denosumab compared to placebo. Despite the reduction in mean pore diameter, the prevalence of eroded pores was not changed ($p = 0.78$) but their contribution to the total pore area increased significantly ($p < 0.001$) in the denosumab-treated patients. In contrast, prevalence, size, and contribution to the total pore area of eroded-formative and formative pores were significantly reduced ($p < 0.001$) in the denosumab-treated patients. On the periosteal surface, denosumab-treatment resulted in a significant reduction of formative surfaces ($p = 0.036$), while the prevalence of eroded surfaces increased significantly ($p = 0.009$) compared to placebo.The cortical histomorphometry demonstrates that denosumab delays the transition from erosion to formation in the remaining intracortical and periosteal remodeling events, likely due to an absence of osteoclasts and their coupling factors. We observed no modeling-based bone formation on the periosteal surfaces, as previously shown in femurs of denosumab-treated monkeys.

Preliminary Data From a First-in-Human, Randomized, Double-blind, Placebo-Controlled, Phase 1 Study of MBX?2109, a Once-Weekly Parathyroid Hormone Replacement Therapy, in Healthy Adults *Mary Jane Geiger[1], Martin Frenzel[2], Richard Bergstrom[3], Patricia Carney[1], Richard DiMarchi[4]. [1]MBX Biosciences, United States. [2]Cytel Inc, United States. [3]B2S Life Sciences, United States. [4]MBX Biosciences and Indiana University, Department of Chemistry, United States

Background: Hypoparathyroidism (hypoPT) is a rare condition characterized by parathyroid hormone (PTH) deficiency resulting in hypocalcemia and hyperphosphatemia. Standard of care with large doses of active vitamin D and calcium fails to adequately and consistently control serum calcium and disease symptoms. MBX 2109 is a novel PTH peptide prodrug being developed as a treatment for hypoPT. The N- and C- termini are respectively extended by 2 and 1 amino acids, with the same fatty acid attached at each end of the prodrug. MBX 2109 chemically converts to active drug by an intramolecular cyclization controlled by temperature and pH. This releases a fatty acylated, N-terminal dipeptide of MBX 2109 and an active drug containing a C-terminal fatty acid with full and selective binding potency for the PTH type 1 receptor. The fatty acids bind plasma proteins and extend circulating residence time of MBX 2109 and active drug. We evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of single and multiple ascending doses

(SAD/MAD) of MBX 2109 in healthy adults.Methods: This was a phase 1, randomized, double-blind, placebo-controlled, SAD/MAD trial (NCT05158335) in 76 healthy adults. SAD/MAD cohorts comprised up to 8 or 10 adults each (6-8 active, 2 placebo) who received subcutaneous doses of 50-600 ?g (SAD, 5 dose levels) or 200-900 ?g (MAD, 4 dose levels, 4 doses once weekly [QW]). Endpoints included plasma concentrations of MBX 2109 and active drug, albumin-adjusted serum calcium, and intact PTH(1-84) levels.Results: After single MBX 2109 doses, MBX 2109 and active drug concentrations increased linearly and dose proportionally (Figure). The geometric mean half-life of MBX 2109 and active drug was ~3.4-4.2 and ~5.5-6.9 days, respectively, across dose groups, supporting QW dosing. MBX 2109 200-900 ?g QW were associated with dose-related increases in mean albumin-adjusted serum calcium and concomitant suppression of mean intact PTH(1-84) levels. MBX 2109 was generally well tolerated (mostly mild treatment-emergent adverse events [AEs]) with no drug-related serious or severe AEs. No doses were associated with dose-limiting toxicity. Injection site reactions were generally mild (primarily erythema).Conclusions: MBX 2109 and active drug PK and PD support QW administration and demonstrate MBX 2109's pharmacologic effect in healthy adults, supporting advancement into phase 2 clinical development.

Figure. Arithmetic Mean Concentration Time Profiles by Dose for the MBX 2109 Prodrug (A) and Active Drug (B) After Single Doses of MBX 2109.

Citrate, a critical TCA cycle intermediate, is present in bone at high concentrations (1-5 wt%) where it is bound to mineral apatite surfaces in a pattern compatible with a structural role. We previously showed that osteoblasts use a specialized metabolic pathway, mediated by the plasma membrane citrate transporter SLC13A5, to regulate uptake, endogenous production and deposition of citrate into bone. Loss of function of this pathway impairs mineralization of bones and teeth in young mice and in children with mutations in SLC13A5 due to increased mineral citrate. Since other studies have suggested that deletion of Slc13a5 in mice mitigates age-related cardiovascular and metabolic pathologies and reducing the expression of the I'm not dead yet (Indy) gene, an orthologue for Slc13a5, increases lifespan in Drosophila melanogaster and C. elegans, we hypothesized that SLC13A5 exerts a unique function in skeletal aging in mice. Furthermore, we translated our findings in humans using a drug target Mendelian Randomization (MR) approach from UK biobank data.We compared young (10 wks) and aged (52 wks) osteoblast-specific Slc13a5 (Slc13a5Oc-cre) mutant mice to littermate Slc13a5fl/fl controls of the respective age. While young female Slc13a5Oc-cre mice exhibited reduced cortical thickness ($p<0.01$) and increased fragility (reduced ultimate moment, $p<0.05$) in 3pt bending tests as we reported earlier, old female Slc13a5Oc-cre mice exhibited a striking reversal of the phenotype marked by a 50% increase in elasticity (Young's modulus, $p<0.05$) without affecting the moment of fracture. Similarly, old male Slc13a5Oc-Cre mice show significant widening of the bone ($p<0.001$) and increased bone strength by 3pt bending (increased ultimate moment, $p<0.05$), while young male mutants were phenotypically normal. In humans, we observed that SNPs associated with reduced function of SLC13A5, indicated by increased plasma citrate levels, were associated with lower risk of osteoporosis in UK Biobank participants (-0.0034 +/-0.0013, $p<0.0097$), while an association between osteoporosis risk and plasma citrate levels in general, was not found (-0.000443 +/-0.0011, $p<0.6877$), indicating that the effect is mediated by SLC13A5. Together, our mechanistic data in mice and MR studies in humans suggest that reducing the function of SLC13A5 in older age has beneficial effects on age related bone loss, which renders pharmacological inhibition of SLC13A5 as a promising approach to treat osteoporosis.

Impaired Fracture Healing in Novel Transchromosomic TcMac21 Down Syndrome Mice *Catrina Silveira[1], KIRBY M. SHERMAN[2], Alyssa Falck[3], Lindsay Dawson[4], Dana Gaddy[5], Larry Suva[6]. [1]Texas A&M University, Departments of Veterinary Physiology & Pharmacology, United States. [2]Texas A&M University , . [3]Texas A&M University, . [4]Texas A&M University College of Veterinary Medicine, United States. [5]College of Veterinary Medicine, Texas A&M University, United States. [6]Texas A&M University, College of Veterinary Medicine and Biomedical Sciences, United States

Down Syndrome (DS) (trisomy of human chromosome 21 (Hsa21) (Ts21)) occurs in approximately one in 800 live births. Low BMD in Ts21 is secondary to low bone mass accrual, which contributes to significantly increased fracture risk and fracture non-union. Recently we demonstrated that long-bone fracture healing is significantly impaired in DP16 DS mice, ultimately resulting in fracture non-union. These results prompted us to investigate long-bone fracture repair using novel human transchromosomic (Tc) mouse models using Tc1 and Tc(HSA21q;MAC)1Yakaz (TcMac21) murine DS models. Tc1 carries 158 of 213 functional Hsa21 protein coding genes but is mosaic (with each individual Tc1 animal unique), whereas TcMac21 contains 93% of Hsa21 protein coding genes, and is not mosaic. Thus, TcMac21 is the most complete genetic DS mouse model to date, yet no detailed skeletal analyses have been reported. Both Tc1 and TcMac21 replicate multiple DS phenotypes including cardiac, craniofacial, and neurocognitive abnormalities. Tc1 DS mice have no basal bone phenotype regardless of age or gender. Like DP16 DS mice, male TcMac21 DS mice have decreased BMD at both 8 weeks and 4 months of age as well as significantly decreased BV/TV, with increased Tb. Sp and decreased Ct. Th compared to WT. Despite the differences in basal bone phenotype, both TcMac21 and Tc1 DS mice exhibit significantly impaired fracture healing. Fractures were induced using the middle phalanx (P2) non-stabilized fracture model. P2 fractures were induced on digits II and IV of the hindfeet of 16-week-old male TcMac21 and Tc1 DS mice. Following fracture, sequential in vivo ?CT was utilized to determine anatomical changes over 42 days post fracture (DPF). Analysis revealed that both male TcMac21 and Tc1 DS mice exhibited lower percent fracture healing (0 of 8; 0% and 1 of 14; 7.1% respectively) at 42 days DPF compared to WT counterparts. Collectively, these data demonstrate that TcMac21 DS mice (like other DS mice) exhibit a low bone mass phenotype and that both TcMac21 and Tc1 DS mice have impaired fracture healing. TcMac21 is a new humanized model of DS, with a freely segregating Hsa21 with which to further study the skeletal complications of DS. Ongoing studies targeting identification of the cellular mechanisms specific to DS bone repair in multiple Tc and other DS mouse strains will be paramount to translate clinically to the management of fracture non-union in Ts21 humans.

Correction of Paradoxical Mineralization in murine CKD-MBD with ENPP1 Enzyme Biologics *Hana Kim[1], Tayyaba Ishaq[1], Paul Stabach[1], Thomas Carpenter[2], William O'Neill[3], Demetrios Braddock[1]. [1]Yale University Department of Pathology, United States. [2]Yale University Department of Pediatric Endocrinology, United States. [3]Emory University, Department of Nephrology, United States

Background: Chronic Kidney Disease-Mineral & Bone Disorder (CKD-MBD) is a prevalent mineralization disorder characterized by medial arterial calcifications and decreased bone mass, in which bone mass inversely correlates with vascular calcifications in a 'Paradoxical Mineralization' disorder to underscore the confusing pathogenesis. Plasma levels of pyrophosphate (PPi) are reduced in CKD patients, suggesting a potential role for the enzyme producing PPi, ENPP1, in the pathogenesis of CKD-MBD.Experimental Plan: To induced CKD we placed mice on a high phosphate, high calcium, low magnesium diet (1.2% Ca, 1.8% Pi, 0.04% Mg) and alternated adenine between 0.15% - 0.3% over 33 weeks in a manner similar to previous murine CKD models induce with an alternating adenine diet (Jia et al. BMC Nephrology 2013, 14:116). Once the animals had developed renal failure (BUN>60 mg/dl) we began dosing the mice with weekly doses of either vehicle or soluble

(1118) or bone targeted (2000) ENPP1-Fc, monitoring BUN and plasma PPi concentrations weekly. At 33 weeks the animals were sacrificed and aortic vascular calcifications were chemically quantitated, and subcutaneous calcifications and cardiac calcifications were assessed by weight and micro-CT, respectively. Bone mineralization in the animals was assessed using biomechanical testing of femurs and micro-CT analysis of tibias.Results: The high-adenine, high-phosphate diet induced progressive renal failure in CKD mice, marked by elevated BUN levels and reduction of plasma PPi levels, which inversely correlated with BUN and markedly dropped on the final week for the diseased groups. With respect to the untreated CKD group, both variants of our ENPP1 enzyme significantly reduced aortic calcification, maintaining low levels comparable to the wild-type. Additionally, comparison of bone biomechanical properties showed significant improvement in stiffness and maximum load in both treatment groups. Micro-CT scans of tibial trabecular bone also showed improved trabecular number, thickness and spacing in the biologic-treated mice. Finally, untreated CKD mice demonstrated an inverse correlation between vascular calcification and Trabecular BV/TV, cortical thickness, and maximum load of femurs in biomechanical testing, reproducing the paradoxical mineralization present in human CKD-MBD.Conclusions: Our studies demonstrate that a modified version of the alternating adenine diet reproduces paradoxical mineralization present in humans with CKD-MBD and demonstrates prevention of vascular calcification and amelioration of the bone mineral abnormalities with ENPP1 biologics, suggesting a role for ENPP1 in the pathogenesis of CKD-MBD, and treatment of the mineralization phenotype with recombinant ENPP1-Fc.

Pooled single-cell CRISPRi screen in hFOB1.19 cells identifes effector genes at BMD GWAS loci *Mitchell Conery[1], James Pippin[2], Yadav Wagley[6], Andrew D. Wells[2], Benjamin F. Voight[4], Babette Zemel[5], Kurt Hankenson[6], Alessandra Chesi[4], Struan Grant[7]. [7]Children s Hospital of Philadelphia / University of Pennsylvania, United States

Genetic factors strongly influence bone mineral density (BMD) and osteoporosis risk over time. To date, genome-wide association studies (GWAS) have discovered over 1,100 independent BMD signals; however, the causal variant(s) and respective effector gene(s) for the majority of these loci remain unknown. We previously published the results of a 3D genomics-based 'variant-to-gene' mapping method for BMD loci based on ATAC-seq, RNA-seq, and chromatin confrmation capture data from hMSC-derived osteoblasts. We have since applied this approach, which links putative causal variants in open chromatin to candidate effector genes via chromatin interactions with open promoters, to a dataset derived from the human fetal osteoblast 1.19 cell line (hFOB). For validation of both sets of fndings at scale, we conducted a CRISPRi screen in hFOBs differentiated for fve days. To reduce background noise and avoid issues stemming from non-random assortment of guide RNAs, we executed the screening process at a low multiplicity of infection (~1 guide RNA per cell). We targeted 89 GWAS-tagged distal regulatory elements linked to one or more known osteoblast-expressed genes via chromatin interaction and observed effects on gene expression in a 1Mb range via single-cell RNA sequencing (scRNA-seq). Post-screening, we used CellBender to denoise our data and a two-tiered strategy to eliminate cellular debris and doublets. This approach employed the clustering of low-complexity cells and stringent fltering of droplets exhibiting >90,000 unique molecular identifers (UMIs) or >10% mitochondrial reads. We ultimately retained 27,383 high-quality cells that received a single unique guide. Using SCEPTRE and the top 15 expression principal components as covariates, we identifed 22 successful CRISPRi perturbations for 19 of the targeted elements. We observed eight connections implicated via our mapping strategy, for example, CPED1, a locus previously reported by our group, as well as 14 novel implicated genes including two HOXD genes that suggest an important role for developmental patterning in the establishment and maintenance of BMD. These results warrant confrmation of the BMD modulating effects of all 22 genes with siRNA knockdown and paired functional assays. In conclusion, our strategy in the osteoblast-lineage has yielded crucial functional insights for BMD GWAS loci and provides a methodological framework for studying the genomics of other musculoskeletal traits and diseases.

Measuring in vivo musculoskeletal metabolism at a single-organelle level *Kai Chen[1], Nathan Pavlos[2], Jiake Xu[2], Matthew Greenblatt[3], Killugudi-Swaminatha Iyer[2], Haibo Jiang[4]. [1]The University of Western Australia, Australia, [2]University of Western Australia, Australia, [3]Weill Cornell Medical College, United States, [4]University of Hong Kong, China

Metabolism refers to a series of chemical reactions that occur within living organisms. Musculosketal system is highly metabolically active and exhibits enormous metabolic heterogeneity, which is challenging to measure. An in vivo investigation of metabolism is critical as it is difficult to recapitulate in vitro, where cells exhibit distinct metabolic behaviors and dependencies. Therefore, the holistic understanding of musculoskeletal biology and diseases requires the in vivo spatial mapping of the chemistry and metabolism across organelles, cells, and matrix. However, this remains unresolved with existing molecular imaging approaches. The mineralized nature of musculoskeletal tissues poses additional challenges to this endeavor.Here, using correlative electron and ion microscopy (CEIM), we have developed an imaging platform specialized for the musculoskeletal system, enabling the in vivo metabolic profiling of cells and matrix down to a single-organelle level. Electron microscopy (EM) provided the ultrastructural details, and the same area, mapped by ion microscopy (IM) using nanoscale secondary ion mass spectrometry (NanoSIMS) intrument, enabled the visualization of chemical elements (e.g., 1H, 12C-, 31P-, 32S-) with a spatial resolution down to approximately 40 nm. Following the oral administration of stable isotope-labelled (i.e., 13C, 15N) amino acids in mice over time periods ranging from minutes to weeks, we spatiotemporally profiled the chemcial elements and metabolic heterogeneity across single cells (e.g., osteoblasts, osteoclasts, chondrocytes, tenocytes, myocytes) and single organelles (e.g., ER, Golgi apparatus, secretory grannules, mitochondria) in vivo. Furthermore, our data also revealed the diverse matrix renewal patterns and aging-related decline throughout the musculoskeletal system. Taken together, our study delivered a landscape of nanoscale metabolim and matrix renewal in the musculoskeletal system in vivo.

A CNP Analog as Adjuvant Treatment for the Growing Osteogenesis Imperfecta Mouse: A Pilot Study *MICHAEL BOBER[1], Ketsia Seide[2], Jack Mulcrone[2], Erin Carter[2], Nancy Pleshko[3], Cathleen Raggio[4]. [1]Nemours Children's Hospital, Delaware, [2]Hospital for Special Surgery, United States, [3]Temple University, United States, [4]HSS, United States

Purpose: Osteogenesis imperfecta (OI) is a heterogenous type 1 collagenopathy characterized by bone fragility. Bisphosphonates decrease fracture incidence and are utilized to manage moderate to severe forms of OI in children. C-type natriuretic peptide (CNP) is produced in the growth plate and positively regulates linear bone growth. This study aims to evaluate if the addition of a CNP Analog (vosoritide) to standard bisphosphonate (alendronate (ALN)) therapy will reduce fracture incidence, improve growth, increase bone mineral density (BMD), and/or improve bone strength in a growing oim/oim mouse model of moderate-to-severe OI.Methods: Starting at 2 weeks of age, growing oim/oim mice (N=17) were divided into 4 groups, saline-treated (controls, N=8), and treated oim/oim mice where all received weekly ALN and one of 3 CNP dosages: 20 ug/kg 5 days/week (20x5) (N=3), 20 ug/kg 3 days/week (20x3) (N=3), or 10 ug/kg 3 days/week (10x3) (N=3). Faxitron images were taken at 2 and 14 weeks (sacrifice) to asssess femoral length, vertebral height, and other bone microstructural parameters by microcomputed tomography analysis. Results: At sacrifice, mice in the 20x5 group had no new fractures, compared to 1 fracture in 1 mouse in both the 20x3 and 10x3 groups. All 3 treatment groups had increased femoral lengths compared to the untreated oim/oim mice (Fig 1); the greatest increase was in the 20x5 group with the 20x3 and 10x3 having similar increases. All treated groups had an increase in vertebral height; both the 20x5 and 10x3 groups had higher vertebral heights than the 20x3 group, but were not different from each other. In comparison to untreated oim/oim mice, all 3 dosage groups had increased cortical bone tissue mineral density (TMD), cortical bone mineral density (BMD), cortical bone thickness, trabecular bone volume fraction (BVF), trabecular BMD, and trabecular bone number. All 3 dosage groups had decreased trabecular bone separation (Fig 2).Conclusion: In this preliminary pilot study, it appears that the adjuvant treatment with a CNP analog results in an overall increase in both femoral and vertebral heights without compromising fracture reduction. In addition, the combination treatment appears to have an additive beneficial effect on both trabecular and cortical bone, the latter of which was not seen with bisphosphonates alone. Continued enrollment will yield the best dosage to maximize the positive bone effects.We thank BioMarin for their grant support.
